A host-based IDS is installed on a single host and monitors all traffic coming into the host. A host-based IDS can analyze encrypted traffic because the host operating system decrypts that traffic as it is received.

A network-based IDS is a dedicated device installed on the network. It analyzes all traffic on the network. It cannot analyze encrypted traffic because the packet contents are encrypted so that only the recipient can read the packet contents.

A protocol analyzer examines packets on the network, but it cannot look at the contents of encrypted packets.

A port scanner probes a device to identify open protocol ports.

A VPN concentrator is a device used to establish remote access VPN connections.

q_ids_host_02_secp8

What do host-based intrusion detection systems often rely upon to perform detection activities?

Answers:

- Network traffic
- ***Auditing capabilities**
- External sensors
- Remote monitoring tools

Explanation:

A host-based IDS often relies upon the host system's auditing capabilities to perform detection activities. The host-based IDS uses the logs of the local system to search for attack or intrusion activities.

Host-based IDSs do not analyze network traffic, use external sensors, or rely upon remote monitoring tools.

q_ids_host_03_secp8

What is the MOST common form of host-based IDS that employs signature or pattern-matching detection methods?

Answers:

- ***Antivirus software**
- Firewalls
- Honeypots
- Motion detectors

Explanation:

Antivirus software using signatures is the most commonly deployed form of a host-based IDS.

Firewalls are primarily designed to secure the network from cyberattacks. They check all incoming and outgoing traffic on a network according to a defined set of rules, not signature or pattern-matching detection methods.

While honeypots help to refine an organization's intrusion detection system (IDS) and threat response, they do so by mimicking a target for hackers, and uses their intrusion attempts to gain information about cybercriminals and the way they are operating or to distract them from other targets.

Motion detectors are hardware that sense physical movements to perform tasks such as helping to turn on outside lights. They do not employ signature or pattern-matching detection methods.

q_ids_ids_01_secp8

Which security mechanism can be used to detect attacks that originate on the internet or from within an internal trusted subnet?

Answers:

- Firewall
- ***IDS**
- Security alarm
- Biometric system

Explanation:

An IDS is a security mechanism that can be used to detect attacks that originate on the internet or from within an internal trusted subnet.

A firewall is only able to filter traffic crossing through its interfaces. So, firewalls are unlikely to detect attacks within trusted areas that are not filtered.

A security alarm is a form of physical intrusion detection. In other words, it is not suited for detecting electronic or online attacks.

Biometric systems are a form of an authentication mechanism, not a detection mechanism.

q_ids_ids_02_secp8

Which of the following is a security service that monitors network traffic in real time or reviews the audit logs on servers looking for security violations?

Answers:

- Firewall
- Switch
- Padded cell
- ***IDS**

Explanation:

An IDS (intrusion detection system) is a security service that monitors network traffic in real time or reviews the audit logs on servers looking for security violations.

Firewalls filter traffic crossing a border of a network environment in order to block unauthorized or security-violating traffic.

A switch is a networking device used to establish temporary electronically dedicated links between two systems to improve throughput and communications isolation.

A padded cell is a fake network environment generated to lure and snare intruders.

q_ids_ids_03_secp8

An active IDS system often performs which of the following actions? (Select two.)

Answers:

- Requests a second logon test for users performing abnormal activities.
- ***Updates filters to block suspect traffic.**
- ***Performs reverse lookups to identify an intruder.**
- Traps and delays the intruder until the authorities arrive.
- Cannot be detected on the network because it takes no detectable actions.

Explanation:

An active IDS performs behaviors that can be seen by anyone watching the network. Usually, these actions are necessary to block malicious activities or discover the identity of an intruder. Updating filters and performing reverse lookups are common behaviors of an active IDS.

No form of IDS requires users to perform a second logon based on questionable activities. There are some authentication systems, such as CHAP, that periodically re-authenticate, but that is done at random time intervals and is not visible to the user. A solution that serves to trap and delay the intruder until the authorities arrive describes a man trap (a physical security mechanism). However, this definition could be stretched to include honeypots and padded cells (logical or technical security mechanisms often used in conjunction with an IDS).

A passive IDS cannot be detected on the network because it takes no detectable actions.

q_ids_ids_04_secp8

Which of the following devices can monitor a network and detect potential security attacks?

Answers:

- ***IDS**
- Proxy
- CSU/DSU
- DNS server

Explanation:

An intrusion detection system (IDS) is a special network device that can detect attacks and suspicious activity.

A proxy server is a type of firewall that can filter based on upper-layer data.

A CSU/DSU is a device that converts the signal received from the WAN provider into a signal that can be used by equipment at the customer site.

A DNS server provides IP address-to-host name resolution.

q_ids_ids_05_secp8

An IT security manager at a technical college wants to increase the use of controls that generate alerts where ongoing attacks are suspected in the organization's network infrastructure.

Which of the following is a suitable illustration of this type of control?

Answers:

- ***Implementing an intrusion detection system**
- Using strong password policies
- Establishing a secure firewall
- Regularly updating antivirus software

Explanation:

An intrusion detection system (IDS) is a detective control that monitors network traffic and analyzes it for signs of possible intrusions, such as security threats or malicious activities.

Although important, strong password policies are typically preventive controls. They work to prevent unauthorized access by requiring users to set strong passwords but do not actively detect breaches or malicious activities.

Firewalls are primarily preventive controls. They prevent unauthorized access to or from a network by controlling incoming and outgoing traffic based on predetermined security rules. They do not actively detect breaches or malicious activities.

Regularly updating antivirus software is a preventive control. Updated antivirus software helps prevent malware from infecting the system but does not detect breaches or security incidents actively.

q_ids_ids_06_secp8

An e-commerce company recently identified suspicious activity on its web-based application suggesting a zero-day exploit. The security team suspects that a vulnerability in the application might be under active exploitation by malicious actors before the company identified and patched it.

With no known fixes available for a zero-day exploit, what should be the initial course of action for the security team to minimize potential damage and safeguard the application and its users?

Answers:

- ***Implement intrusion detection systems (IDS) and application firewalls.**
- Perform a comprehensive system backup.
- Update the antivirus software on all company devices.
- Enforce password changes for all users.

Explanation:

IDS and application firewalls provide immediate protection by identifying and blocking potentially malicious activity, thus serving as an effective response to zero-day exploits in a web-based application.

Although system backups are important for data recovery, they do not directly address or prevent an active zero-day exploit.

While updating antivirus software can help protect against known threats, it is often ineffective against zero-day exploits as these are previously unknown vulnerabilities that antivirus signatures do not cover yet.

Enforcing password changes for all users might improve account security, but it doesn't directly address the zero-day exploit in the application's code.

q_ids_ips_01_secp8

You are concerned about attacks directed at your network firewall. You want to be able to identify and be notified of any attacks. In addition, you want the system to take immediate action to stop or prevent the attack, if possible.

Which tool should you use?

Answers:

- IDS
- ***IPS**
- Packet sniffer
- Port scanner

Explanation:

Use an intrusion prevention system (IPS) to both detect and respond to attacks.

An intrusion detection system (IDS) can detect attacks and send notifications, but it cannot respond to attacks.

Use a port scanner to check for open ports on a system or a firewall.

Use a packet sniffer to examine packets on the network.

q_ids_ips_02_secp8

Which of the following devices is capable of detecting and responding to security threats?

Answers:

- IDS
- ***IPS**
- DNS server
- Multi-layer switch

Explanation:

An intrusion prevention system (IPS) can detect and respond to security events. An IPS differs from an IDS because it can respond to security threats, not just detect them.

A DNS server provides IP address-to-host name resolution.

A multi-layer switch uses an ASIC module to switch packets based on packet or data content instead of using the CPU and software.

q_ids_ips_03_secp8

Your organization uses a web server to host an e-commerce site.

Because this web server handles financial transactions, you are concerned that it could become a prime target for exploits. You want to implement a network security control that analyzes the contents of each packet going to or from the web server. The security control must be able to identify malicious payloads and block them.

What should you do?

Answers:

- Implement an application-aware IDS in front of the web server.
- ***Implement an application-aware IPS in front of the web server.**
- Install an anti-malware scanner on the web server.
- Implement a packet-filtering firewall in front of the web server.
- Implement a stateful firewall in front of the web server.

Explanation:

You should implement an application-aware IPS in front of the web server. Even though an application-aware IDS can analyze network packets to detect malicious payloads, only an application-aware IPS can both detect and block malicious packets. Because of this, an application-aware IPS would be the most appropriate choice.

Installing an anti-malware scanner on the web server itself is a good idea, but it can only detect malware after it has been installed on the server.

Using a packet-filtering firewall or a stateful firewall is also a good security measure, but neither are capable of inspecting the contents of network packets.

A packet-filtering firewall can only filter based on IP address, port, and protocol.

A stateful firewall can only monitor the state of a TCP connection. These devices should be used in conjunction with an IDS or an IPS to protect a network.

q_ids_logs_anomaly_secp8

A security architect at a multinational corporation designs a comprehensive security strategy to defend against advanced persistent threats (APTs).

The strategy includes real-time analysis of network traffic, detection of unknown threats, correlation of events across different layers, and automatic response to mitigate risks. The architect also ensures compliance with international regulations on data privacy.

Which data sources and security components combination would BEST align with this multifaceted approach?

Answers:

- ***Intrusion prevention system/intrusion detection system (IPS/IDS) logs, anomaly detection, and automated response mechanisms**
- Application logs and endpoint security
- Network logs, firewall logs, and operating system (OS)-specific security logs
- Vulnerability scans, packet captures, and dashboards

Explanation:

Intrusion prevention system/intrusion detection system (IPS/IDS) logs, anomaly detection, and automated response mechanisms provide real-time network traffic analysis, detect unknown threats through anomaly detection, correlate events, and enable automatic response, ideal for advanced security requirements.

Application logs and endpoint security provide insights into software activities and endpoint protection but lack real-time network analysis and advanced threat detection capabilities.

Network, firewall, and operating system (OS)-specific security logs offer information about network operations and connections but don't provide real-time analysis or automatic response to advanced threats.

Vulnerability scans, packet captures, and dashboards provide a view of system weaknesses and network packets but miss real-time threat detection and mitigation capabilities.

q_ids_network_based_secp8

An eCommerce company utilizes an advanced firewall for network protection. However, due to an increasing variety of threats, their existing setup is not enough. The company considers enhancing its firewall with intrusion detection and prevention systems (IDS/IPS).

What should be their primary approach in this scenario?

Answers:

- ***Add network-based IDS/IPS and maintain the firewall rules.**
- Discard firewall rules and rely solely on network-based IDS/IPS.
- Abandon the firewall and adopt host-based IDS/IPS.
- Keep the firewall and ignore IDS/IPS adoption.

Explanation:

Introducing network-based IDS/IPS while keeping firewall rules will augment the company's network protection. The IDS/IPS will monitor for known threats and unusual network packet behavior while the firewall continues filtering traffic based on set rules.

Discarding firewall rules to rely solely on network-based IDS/IPS neglects the benefits of firewall's traffic filtering, resulting in less comprehensive protection.

Abandoning the firewall for host-based IDS/IPS lacks the network-wide threat detection and doesn't leverage the firewall's traffic filtering capabilities.

Keeping the firewall while ignoring IDS/IPS adoption doesn't capitalize on the added security layer that IDS/IPS systems provide. This could result in missed threats.

q_ids_placement_01_secp8

A company has expanded its operations to a new location and is setting up its network infrastructure. A significant part of this setup includes strategically placing devices for optimal security and efficiency.

How should the network security manager decide the optimal placement of the intrusion detection system (IDS) in the new network topology to ensure maximum visibility and efficiency without impacting overall network performance?

Answers:

- Place the IDS outside the firewall.
- Place the IDS at the end of the network.
- ***Place the IDS directly behind the router.**

- Place the IDS near the servers.

Explanation:

Placing the IDS directly behind the router ensures visibility of all incoming and outgoing traffic, which is crucial for detecting any unusual patterns or potential threats.

Placing the IDS outside the firewall exposes it to all internet traffic, including a lot of noise and potential direct attacks on the IDS itself, which is not optimal.

Placing the IDS at the end of the network could result in it only seeing outbound traffic, thus limiting its visibility and effectiveness.

While placing the IDS near the servers could provide some visibility into the traffic going to and from the servers, it will not give it a comprehensive view of all network traffic.

q_ids_placement_02_secp8

A medium-sized organization is upgrading its network infrastructure to secure its enterprise infrastructure by implementing an intrusion prevention system (IPS) and an intrusion detection system (IDS).

The organization has sensitive data in different security zones, and the IT manager has concerns regarding the attack surface and network connectivity.

Which of the following placements of the IPS/IDS devices would be MOST effective in this scenario?

Answers:

- ***Place the IPS/IDS devices at the network perimeter to monitor inbound and outbound traffic.**
- Place the IPS/IDS devices just inside the organization's firewall to monitor the internal network.
- Place the IPS/IDS devices at each end of the VPN tunnel to monitor remote access.
- Place the IPS/IDS devices near the load balancer to monitor traffic distribution.

Explanation:

Placing the IPS/IDS devices at the network perimeter allows for monitoring of all inbound and outbound traffic, providing comprehensive visibility and enabling immediate response to potential threats.

While placing the IPS/IDS devices just inside the firewall can help monitor internal network traffic, it would not provide comprehensive visibility into inbound and outbound traffic.

Although placing the IPS/IDS devices at each end of the VPN tunnel can help monitor remote access, it would not provide complete visibility into all network traffic.

Placing the IPS/IDS devices near the load balancer can help monitor traffic distribution, but it would not provide comprehensive visibility into all network traffic.

q_ids_placement_03_secp8

A large organization is redesigning its network infrastructure to increase security and reduce the potential attack surface. The organization considers implementing an intrusion prevention system (IPS) and an intrusion detection system (IDS) into its security zones.

The IT manager wants to secure connectivity and considers different network appliances and port security measures.

Which of the following options BEST describes the benefits and disadvantages of placing the IPS/IDS devices inline with the network traffic?

Answers:

- ***Inline placement allows for active prevention measures but can become a single point of failure.**
- Inline placement increases the attack surface but provides comprehensive traffic visibility.
- Inline placement reduces connectivity but allows for passive detection.
- Inline placement improves port security but increases network latency.

Explanation:

Inline placement of IPS/IDS devices allows for active prevention measures, such as blocking malicious traffic, but can become a single point of failure if the device malfunctions, potentially disrupting network traffic.

Inline placement does not inherently increase the attack surface, and while it provides comprehensive traffic visibility, this does not address the risk of becoming a single point of failure.

Inline placement does not inherently reduce connectivity, and while it can allow for passive detection, it also allows for active prevention measures not highlighted in this option.

Inline placement does not inherently improve port security, and while it can potentially increase network latency, this does not address the benefit of active prevention measures.

q_ids_placement_04_secp8

A multinational corporation wants to enhance its security infrastructure by deploying an intrusion detection system (IDS) across its global network. The IT manager is considering the placement of IDS sensors to ensure comprehensive network visibility.

Which IDS sensor placement is the MOST effective in this scenario?

Answers:

- ***Place the IDS sensors at network choke points.**
- Place the IDS sensors on the internal network.
- Place the IDS sensors on the external network.
- Place the IDS sensors near the network perimeter.

Explanation:

Placing the IDS sensors at network choke points ensures that they can monitor both inbound and outbound traffic, providing comprehensive visibility across the network. This helps detect malicious activity at the earliest possible stage.

While placing the IDS sensors on the internal network can help monitor outbound traffic, it does not provide comprehensive visibility as it may not capture all inbound traffic.

Putting the IDS sensors on the external network can help monitor inbound traffic but may not provide complete visibility into outbound traffic.

Locating the IDS sensors near the network perimeter can help monitor internal network traffic but may not provide complete visibility into all inbound and outbound traffic.

q_ids_signature_01_secp8

Which IDS method searches for intrusion or attack attempts by recognizing patterns or identifying entities listed in a database?

Answers:

- Heuristics-based IDS
- Anomaly-analysis-based IDS
- Stateful-inspection-based IDS
- ***Signature-based IDS**

Explanation:

A signature-based IDS, or pattern-matching-based IDS, is a detection system that searches for intrusion or attack attempts by recognizing patterns that are listed in a database.

A heuristics-based IDS is able to perform some level of intelligent statistical analysis of traffic to detect attacks. Anomaly-analysis-based IDSs look for changes in the normal patterns of traffic.

Stateful-inspection-based IDSs search for attacks by inspecting packet contents and associating one packet with another.

These searches look for attacks in overall data streams rather than individual packets.

q_ids_signature_02_secp8

What does IDS do when using signature recognition use to identify attacks?

Answers:

- ***Makes comparisons to known attack patterns**
- Alerts for exceeding threshold values
- Statistical analysis to find unusual deviations
- Makes comparison of current statistics to past statistics

Explanation:

Signature recognition, also referred to as pattern matching, dictionary recognition, or misuse-detection (MD-IDS), looks for patterns in network traffic and compares them to known attack patterns called signatures.

Anomaly recognition, also referred to as behavior, heuristic, or statistical recognition, monitors traffic to define a standard activity pattern as normal.

Clipping levels or thresholds are defined that identify deviations from the norm. When the threshold is reached, an alert is generated or an action is taken.

Anomaly-based systems can recognize and respond to some unknown attacks (attacks that do not have a corresponding signature file).

q_ids_signature_03_secp8

You have just installed a new network-based IDS system that uses signature recognition.

What should you do on a regular basis?

Answers:

- ***Update the signature files**
- Check for backdoors
- Generate a new baseline
- Modify clipping levels

Explanation:

Signature recognition, also referred to as pattern matching, dictionary recognition, or misuse-detection (MD-IDS), looks for patterns in network traffic and compares them to known attack patterns called signatures. Signature-based recognition cannot detect unknown attacks; they can only detect attacks identified by published signature files. For this reason, it is important to update signature files on a regular basis.

Anomaly recognition, also referred to as behavior, heuristic, or statistical recognition, monitors traffic to define a standard activity pattern as normal.

Clipping levels, or thresholds, identify deviations from the norm. When the threshold is reached, an alert is generated or an action is taken.

q_ids_signature_04_secp8

A cybersecurity analyst for a large organization is enhancing the company's security posture. The analyst notices increased alerts related to a particular known exploit in the company's server software.

The company's intrusion detection system (IDS) has a rule specifically for this exploit.

In the given scenario, which detection method should the analyst modify or enhance to effectively detect and alert for this specific exploit?

Answers:

- ***Signature-based detection**
- Behavioral-based detection
- Anomaly-based detection
- Trend analysis

Explanation:

Since the exploit is known and the IDS already has a rule set for signature-based detection of this specific exploit, enhancing or focusing on signature-based detection would be the most effective method.

Although behavioral-based detection can detect deviations from normal behavior, it is not the primary method for detecting known threats, especially when a signature for the attack is already in place.

Anomaly-based detection focuses on irregularities in the use of protocols. While useful, it is not the primary method when a known exploit signature is in place.

Trend analysis, while valuable for understanding the environment over time and identifying patterns, does not directly detect specific known threats. Its focus is on long-term patterns rather than immediate threats.

q_ids_signature_anomaly_secp8

How does signature-based detection differ from anomaly-based detection in an intrusion detection system (IDS)?

Answers:

- ***Signature-based detection relies on known attack patterns, while anomaly-based detection identifies deviations from normal behavior.**
- Signature-based detection identifies deviations from normal behavior, while anomaly-based detection relies on known attack patterns.
- Both signature-based and anomaly-based detection rely on known attack patterns.
- Both signature-based and anomaly-based detection identify deviations from normal behavior.

Explanation:

Signature-based detection uses known patterns of malicious behavior (or "signatures") to identify potential threats. This method can quickly and accurately detect known threats but may fail to identify new, unrecorded types of attacks. In contrast, anomaly-based detection works by defining what's considered "normal" behavior within a system and then alerting on any behavior that deviates from this norm.

Signature-based detection relies on known attack patterns, while anomaly-based detection identifies deviations from normal behavior.

Anomaly-based detection identifies threats by noting deviations from established norms of system behavior.

Signature-based detection does not identify deviations from normal behavior. It identifies matches to known attack patterns. Anomaly-based detection identifies normal behavior deviations but does not rely on known attack patterns.

q_ids_threat_secp8

A mid-sized tech company has started experiencing regular system slowdowns and data traffic abnormalities. However, its current intrusion detection system (IDS) has generated no alerts.

The IT department relies heavily on the IDS for potential threats and does not actively monitor system metrics or logs.

Which statement is MOST likely true about the situation?

Answers:

- ***The company is facing a new type of threat not recognized by the IDS.**
- The abnormalities are coincidental and do not signify a potential threat.
- The IDS is fully capable of identifying all potential threats.
- The IDS does not need updating as it handles all kinds of threats.

Explanation:

Despite observable anomalies, the absence of alerts from the IDS suggests that the IDS does not recognize the threat.

While it is possible for system slowdowns or data traffic abnormalities to occur naturally due to factors like system updates or increased workload, the consistent occurrence of these anomalies usually indicates a potential threat, which warrants investigation.

The rapid evolution of cybersecurity threats means that a system can only identify some potential threats, especially if the threats are new or highly sophisticated.

Regular updates are crucial for an IDS, as these updates often contain patches for new threats and vulnerabilities. Without regular updates, an IDS may fail to identify newer threats, leaving the organization vulnerable.

q_ids_trend_analysis_01_secp8

A multinational corporation has recently implemented an intrusion detection system (IDS) and intrusion prevention system (IPS) to protect its network infrastructure.

The security team receives many alerts and struggles to manage false positives. The team must optimize the IDS and IPS to identify and prioritize actual threats while minimizing irrelevant alerts.

Which primary strategy should the team adopt to achieve this objective?

Answers:

- ***Implement trend analysis to identify patterns and anomalies, tune the IDS/IPS over time, and prioritize genuine threats.**
- Ignore all alerts from the IDS/IPS to focus on manual monitoring of network traffic.
- Apply signature-based detection rules only to filter out false positives.
- Integrate SELinux policies for a layered security approach, ensuring system-level restrictions to applications and processes.

Explanation:

Trend analysis is the correct approach, as it allows the security team to understand the environment over time, identify patterns, and distinguish anomalies.

Ignoring all alerts from the IDS/IPS is a poor approach as the company would fail to leverage the benefits of these systems, including its ability to detect and prevent security threats more efficiently than manual monitoring.

Applying only signature-based detection rules would not be sufficient because these rules depend on known patterns of attacks.

Integrating Security Enhanced Linux (SELinux) policies provides an additional layer of protection by enforcing mandatory access controls (MAC) at the operating system level. However, on its own, it doesn't directly optimize the IDS/IPS for reducing false positives.

q_ids_trend_analysis_02_secp8

A global organization recently became the target of a wave of cyberattacks and decided to strengthen its network defenses by deploying an IDS/IPS.

However, the large number of alerts the systems generate cause the security team to spend a significant amount of time dealing with false positives. The team wishes to improve the efficiency of these systems by recognizing and prioritizing actual threats while reducing unnecessary alerts.

Which primary approach should the team employ to meet this goal?

Answers:

- ***Implement trend analysis to identify patterns and anomalies, tune the intrusion detection system/intrusion prevention system over time, and prioritize genuine threats.**
- Ignore all alerts from the intrusion detection system/intrusion prevention system to focus on manual monitoring of network traffic.
- Apply signature-based detection rules only to filter out false positives.
- Integrate SELinux policies for a layered security approach, ensuring system-level restrictions to applications and processes.

Explanation:

Trend analysis is the correct approach, as it allows the security team to understand their environment over time, identify patterns, and distinguish anomalies.

Ignoring all alerts from the intrusion detection system/intrusion prevention system is a poor approach as the company would fail to leverage the benefits of these systems, including its ability to detect and prevent security threats more efficiently than manual monitoring.

Applying only signature-based detection rules would not be sufficient because these rules depend on known patterns of attacks.

Integrating SELinux policies provides an additional layer of protection by enforcing mandatory access controls (MAC) at the operating system level. However, on its own, it doesn't directly optimize the IDS/IPS for reducing false positives.

6.4 Protocol Analyzers

As you study this section, answer the following questions:

- What mode must a NIC be in to perform packet sniffing?
- What needs to be configured on a switch so all packets are sent to the sniffing device?
- Why would a network administrator need to use a protocol analyzer?

In this section, you will learn to:

- Analyze network traffic.

The key terms for this section include:

Term	Definition
Protocol analyzer	Hardware or software used for monitoring and analyzing digital traffic over a network. Protocol analyzers go by other names, such as packet sniffers, packet analyzers, network analyzers, network sniffers, or network scanners.

Promiscuous mode	A mode in which the NIC processes every frame it sees, not just those addressed to it.
Port mirroring	A switch mode in which all frames sent to all other switch ports will be forwarded on the mirrored port.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	2.4 Given a scenario, analyze indicators of malicious activity.
	• Network attacks
	  ○ On-path
	  ○ Credential replay
	2.5 Explain the purpose of mitigation techniques used to secure the enterprise.
	• Hardening techniques
	  ○ Disabling ports/protocols
	4.1 Given a scenario, apply common security techniques to computing resources.
	• Monitoring
	4.5 Given a scenario, modify enterprise capabilities to enhance security.
	• Firewall
	  ○ Ports/protocols
	• Implementation of secure protocols
	4.9 Given a scenario, use data sources to support an investigation.
	• Data sources
	  ○ Packet captures

6.4.1 Protocol Analyzers (Lesson Video)

Transcript:

Protocol analyzers are used to capture data packets moving across a network and analyze them. In most cases, you'll see these tools as software programs that run a computer system, but there are hardware analyzers available as well.

Be aware that protocol analyzers are also called packet analyzers, packet sniffers, network analyzers, network sniffers, or network scanners. These terms all mean roughly the same thing.

Some of the more common protocol analyzers are Wireshark, tcpdump, Cain and Abel, and WinDump. In this lesson, I'll go over how these analyzers work and what we use them for.
The most common way to set up a protocol analyzer is to install the program on a computer that's connected to a network switch. This can be a desktop computer, but laptops are also useful as they provide greater mobility.
When we use a protocol analyzer, the computer's network interface card, or NIC, must be placed in promiscuous mode. Promiscuous mode means that the NIC is able to see all packets on the same network segment. In non-promiscuous mode, the NIC only receives packets that are addressed to its MAC address.
Once we set up and configure our computer with the protocol analyzer, we can begin monitoring the packets that run across the network. We can usually just sit back and monitor the data without much interaction. This is known as passive interception.
Once we actually begin capturing packets, there's quite a few things we can do with this data.
Depending on what we're trying to accomplish, there are different ways we can take advantage of the protocol analyzer's features.
For example, a network administrator may use their protocol analyzer to look for specific protocols like SMTP, DNS, POP3, or ICMP that have packets running across the network. The administrator could even detect an employee's unauthorized internet use by scanning URLs that they find in these packets.
The network SecOps team could use their packet analyzer during a vulnerability assessment. This could reveal open ports or whether passwords are being sent in cleartext or not. They could also detect any malformed or fragmented packets, which would indicate that someone is trying to get around the firewall.
Malicious users can also use a protocol analyzer for many of these same purposes. They could use it to fingerprint a system, which means determining which operating system is running based on how the system responds to different types of network traffic.
Malicious users can also use protocol analyzers to perform active interception. This is when the user intercepts data in order to perform attacks or session hijacking.
MAC flooding is another issue for you to be aware of. A bad actor can connect to a switch and, in short, overload it with fake MAC addresses. MAC flooding essentially turns the switch into a hub and allows the hacker to see all passing traffic.
Most times, though, protocol analyzers are used for valid purposes. Just be aware that unscrupulous people sometimes use them to get around security systems.
That'll wrap up this lesson. In this lesson, we looked at protocol analyzers and how they work. We also went over protocol analyzers' many uses and misuses, and we saw how you can utilize this tool for your role in system security. Always remember to put the NIC in promiscuous mode to properly capture data when choosing to use a protocol analyzer.

6.4.2 Protocol Analyzer Facts

A protocol analyzer is hardware or software for monitoring and analyzing digital traffic over a network. Protocol analyzers go by other names, such as packet sniffers, packet analyzers, network analyzers, network sniffers, or network scanners.

This lesson covers the following topics:

- How protocol analyzers work
- Uses of protocol analyzers

How Protocol Analyzers Work

Typically, a protocol analyzer is run on a single device with the intent of capturing frames for all other devices on the network or subnet. Using a packet sniffer this way requires the following configuration changes:

- A network interface card, or NIC, accepts frames addressed only to that NIC by default. To enable the packet sniffer to capture frames sent to other devices, configure the NIC in promiscuous mode (sometimes called p-mode). In p-mode, the NIC processes every frame it sees.
- When using a switch, the switch only forwards packets to the switch port that holds a destination device. This means that when your packet sniffer is connected to a switch port, it does not see traffic sent to other

switch ports. To configure the switch to send all frames to the packet sniffing device, configure port mirroring on the switch. With port mirroring, all frames sent to all other switch ports are forwarded on the mirrored port.

A malicious user that is connected to the switch can accomplish the same thing by running a MAC flooding attack. This attack essentially turns the switch into a hub, and traffic is sent to all ports.

By default, a protocol analyzer is a passive device. It copies frames and allows viewing of frame contents, but it does not allow the capture, modification, or re-transmission of frames. This is referred to as passive interception.

When using a protocol analyzer, the user can filter the frames so they see only the frames with information of interest. You can save the results of a capture to analyze frames at a later time or on a different device.

- Filters show only those frames or packets to or from specific addresses or frames that include specific protocol types.
- A capture filter captures (records) only the frames identified by the filter. Frames not matching the filter criteria are not captured.
- A display filter shows only the frames that match the filter criteria. Frames not matching the filter criteria are still captured but not shown.

Uses of Protocol Analyzers

Depending on the role of the user, a protocol analyzer may have different uses. The following table shows some common roles and how they may use a protocol analyzer:

Role	Protocol Analyzer Usage

Network administrator	A network administrator can use the protocol analyzer to assist in the management of the network and employee usage. The protocol analyzer can help to:
	• Monitor and log network traffic as it is transmitted over the network.
	• Check for specific protocols on the network, such as SMTP, DNS, POP3, and ICMP. Identifying the specific protocols helps to:
	  ○ Identify devices that might be using unallowed protocols, such as ICMP, or legacy protocols, such as IPX/SPX or NetBIOS.
	  ○ Identify traffic that might be sent by attackers.
	• Examine the data contained within a packet. For example, by looking at the packet data, the network administrator can identify users connecting to unauthorized websites.
	• Analyze network performance
	• Troubleshoot communication problems or investigate the source of heavy network traffic

Security operations	The network SecOps team can use the protocol analyzer during a vulnerability assessment. The protocol analyzer can help the SecOps team to: • Identify frames that might cause errors. For example, the network administrator can: ○ Determine which flags are set in a TCP handshake

	○ Detect any malformed or fragmented packets. This would indicate that someone is trying to get around the firewall. • Discover passwords and other sensitive data being sent in cleartext. • Find any open network ports that should not be open.
Malicious user/hacker	A malicious user can use the protocol analyzer to find the same information as the network administrator and SecOps teams. By themselves, protocol analyzers cannot be used to perform an attack. However, protocol tools can be used with protocol analyzers for active interception of network traffic to perform attacks, such as: • Spoofing • Man-in-the-middle attacks • Replay attacks • TCP/IP session hijacking • MAC flooding A hacker can also use the analyzer to perform system fingerprinting. System fingerprinting identifies which operating system the system is running based on how it responds to different types of network traffic.

Common protocol analyzers include:

- Wireshark
- Ethereal
- Dsniff
- Ettercap
- Tcpdump
- Windump
- Cain and Abel

6.4.3 Analyzing Network Traffic (Demo Video)

Transcript:

Wireshark is a network packet analyzer that tries to capture network packets and display the data they carry in as much detail as possible.

Network professionals use Wireshark to troubleshoot network problems, examine security problems, verify network devices, debug network issues, and more. Wireshark can be installed on Windows, Linux, and other operating systems. It's not a firewall or intrusion detection system, and it doesn't keep bad things from happening. But it does a great job of monitoring and measuring activity on a network.
We're going to take a very brief look at Wireshark. There are entire courses on Wireshark, and as you progress professionally, you'll want to learn more about the program.
Let's start with Wireshark's user interface. Throughout this course we'll use Wireshark on Linux and Windows. I'm currently on Kali Linux machine. We're going to use Wireshark from there. Like most programs, Wireshark has a menu at the top. The File menu is similar to other programs, as you can see when we click on it. The same is true for the other menu items across the top.
The main toolbar gives you quick access to the most common Wireshark tasks. The two most common items here are the shark fin, or Start, which starts capturing packets, and this square, which turns red when Wireshark is capturing.

Below that, there's the Filter toolbar. We'll come back to this in a few minutes.
Down here, there's the Packet List pane. This is where all the captured packets are displayed. It only takes a few minutes to see hundreds or thousands of packets, depending on your network traffic. Each line here is a packet that Wireshark has captured, and it's separated in columns up here. You can separate packets by source or destination IP addresses or categorize them in other ways. Whichever one is selected up here will display more detailed information down in the Packet Detail pane.
The Packet Detail pane shows all the details about the selected packet. I can come down here, expand the different areas, and see more details. For those of you who love the OSI model, you'll be very happy to hear that this is listed in the OSI order.
Farther down, we have the Packet Bytes pane. This is a hexadecimal dump of the selected packets. Sometimes, you can see readable information over here, in ASCII. If the bytes aren't readable, this information is replaced with periods.
And finally, at the bottom, we have the status bar.
A lot of the Wireshark interface can be customized, but this is what it looks like with the default settings.
Okay. Let's go back to display filters. When you do some sniffing with Wireshark, you're going to be overwhelmed with all of the packets it will capture. We can filter the ones that aren't needed. I already ran a scan earlier, and my traffic is here.
One way to filter is to use the Expression Builder. For example, let's say I want to filter dhcp. If I look, bootp and dhcp are actually the same thing. If I expand this out, I get lots of things to choose from. I'm going to just leave it as-is.
Now let's go over to the Relation box. We have things such as is present. The double equal sign (==) means equal to. The exclamation and equal (!=) means not equal to. The next several should be self-explanatory, but I want to pick the equal to and then, for the value, type in '10.10.10.1', which is my DHCP server. Now, I'll click OK and see what happens. I'm filtering only my DHCP traffic.
Now, I want to see if there are any cleartext usernames and passwords here. I can do that several ways. I can create a filter by typing in 'http contains admin'. As I type, notice the salmon color. As soon as it's a valid filter, it turns green.
Let's come down here and choose this packet. I'm picking it because it has an external public IP address. I'm going to right-click and select Follow TCP Stream. Now it displays the entire stream related to this conversation. Some of it is readable; some is not. I'm looking for the word Admin. Let's see if we can just do a find for that. I'll click on Find Next until I see something worth looking at. Here, it looks like I found something. It's the word log with the username Admin listed. This is followed by pwd and the password the person typed in. So, with Wireshark, we were able to see a cleartext password. We could also filter other things, like FTP, to find cleartext passwords.
I'll come up and clear this filter.
Another way we can filter is to come down here. If I find something that I think is interesting, I can right-click and apply a filter.
We could spend an hour looking at filters, but let's keep moving on here.
So, we kind of did this already. We know we can look at packets. But what if we wanted to look at the entire conversation between two devices? I can come down here, right-click on one of these, and select Follow TCP Stream. Now, I get this window that pops up with the entire stream. This particular stream isn't very useful, but you get the idea.
So, how many different conversations have been going on here? I can figure that out by coming up to Statistics and selecting Conversations. When I do, my conversations are combined. All the packets are organized neatly. I can choose a few different ways to see my data and then sort by the total size of the bytes, largest to smallest. I have some tabs up here, such as IP versions 4 and 6. I can select TCP to display my TCP conversation. Okay. I'll close this and then clear my filter.
So far, when we look at our packets from Wireshark, we see a bunch of gobbledygook. The good news is that Wireshark has a way to export objects. In our case, we want a file. To do this, we can come up here, to File, go down to Export Objects, and select a category. I can pick HTTP, and I'll get a list of things that downloaded from the web, or we can get objects from our local Windows network by selecting SMB. That's the one I'm going to choose. I only have one file. It's one that I transferred across the network earlier. It's a jpg image file. I'll click on Save and pick a place to save it. I'll pick Desktop, click Save, and close this window.
Now I'll minimize Wireshark, go over to my folders, go to Desktop, and here's the picture that I captured in Wireshark.
That's it for this demo. In this demo, we took a look at Wireshark. We started by going over the Wireshark interface. Then we talked about using filters. We illustrated how to follow conversations in Wireshark. Finally, we ended by exporting an object.

6.4.4 Practice Questions (Section Quiz)

q_prot_analyzers_filter_secp8

You are using a protocol analyzer to capture network traffic. You want to only capture the frames coming from a specific IP address.

Which of the following can you use to simplify this process?

Answers:

- ***Capture filters**
- Switch
- NIC
- Display filters

Explanation:

A capture filter records only the frames identified by the filter. Frames that don't match the filter criteria are not captured.

A switch connects multiple computers together in a network. It is not used to capture specific frames.

A network interface card (NIC) is used to transmit and receive frames addressed to it. It is not used to capture specific frames.

A display filter shows only the frames that match the filter criteria. Frames that don't match the filter criteria are still captured, but are not shown.

q_prot_analyzers_finger_secp8

Which of the following processes identifies an operating system based on its response to different types of network traffic?

Answers:

- Port scanning
- ***Fingerprinting**
- Firewalking
- Social engineering

Explanation:

A hacker can use an analyzer to perform system fingerprinting. System fingerprinting identifies which operating system the system is running based on how it responds to different types of network traffic.

Port scanning pings every port on an external interface or attempts a connection in order to discover which ports are open and active, and which ones are not.

Firewalking uses the traceroute command to discover which services can pass through a firewall or router.

Social engineering exploits human nature to obtain information. A hacker often impersonates someone of authority and requests data.

q_prot_analyzers_mirroring_secp8

You decide to use a packet sniffer to identify the type of traffic sent to a router. You run the packet sniffing software on a device that is connected to a hub with three other computers. The hub is connected to a switch that is connected to the router.

When you run the software, you see frames addressed to the four workstations, but not to the router.

Which feature should you configure on the switch?

Answers:

- Promiscuous mode
- ***Port mirroring**
- Bonding
- Spanning Tree Protocol

Explanation:

A switch only forwards packets to the switch port that holds a destination device. This means that when your packet sniffer is connected to a switch port, it does not see traffic sent to other switch ports. To configure the switch to send all frames to the packet sniffing device, configure port mirroring on the switch. With port mirroring, all frames sent to all other switch ports are forwarded on the mirrored port.

Promiscuous mode configures a network adapter to process every frame it sees, not just the frames addressed to that network adapter. In this scenario, you know that the packet sniffer is running in promiscuous mode because it can already see frames sent to other devices.

Bonding logically groups two or more network adapters together to be used at the same time for a single logical network connection.

Spanning Tree Protocol (STP) runs on a switch and ensures that there is only one active path between switches, allowing for backup-redundant paths.

q_prot_analyzers_output_01_secp8

You are running a packet sniffer on your workstation so you can identify the types of traffic on your network. You expect to see all the traffic on the network, but the packet sniffer only seems to be capturing frames that are addressed to the network interface on your workstation.

Which of the following must you configure in order to see all of the network traffic?

Answers:

- ***Configure the network interface to use promiscuous mode.**
- Configure the network interface to use port mirroring mode.
- Configure the network interface to use protocol analysis mode.
- Configure the network interface to enable logging.

Explanation:

Configure the network interface to use promiscuous mode. By default, a NIC only accepts frames addressed to itself. To enable the packet sniffer to capture frames sent to other devices, configure the NIC in promiscuous mode (sometimes called p-mode). In p-mode, the NIC processes every frame it sees.

Configuring port mirroring on a switch sends all frames to the packet sniffing device. With port mirroring, all frames sent to all other switch ports are forwarded on the mirrored port. Configuring port mirroring would not resolve the issue limited capture of frames.

Network protocol analysis is a network sniffer that captures data for further analysis and understanding. Configuring protocol analysis would only capture and save frames. It would not resolve the issue of limited capturing of frames.

Configuring the network interface to enable logging would provide an additional block to capturing frames that are addressed to the network interface on your workstation.

q_prot_analyzers_output_02_secp8

Which of the following accurately describes what a protocol analyzer is used for? (Select two.)

Answers:

- ***A passive device that is used to copy frames and allow you to view frame contents.**
- ***A device that does NOT allow you to capture, modify, and retransmit frames (to perform an attack).**
- A device that allows you to capture, modify, and retransmit frames (to perform an attack).
- A device that can simulate a large number of client connections to a website, test file downloads for an FTP site, or simulate large volumes of emails.
- A device that measures the amount of data that can be transferred through a network or processed by a device.

Explanation:

A protocol analyzer is a passive device that copies frames and allows you to view frame contents. However, it does not allow you to capture, modify, and retransmit frames (activities that are used to perform an attack).

A load tester simulates a load on a server or service. For example, a load tester might simulate a large number of client connections to a website, test file downloads for an FTP site, or simulate large volumes of emails.

A throughput tester measures the amount of data that can be transferred through a network or processed by a device.

q_prot_analyzers_output_03_secp8

You want to identify traffic that is generated and sent through a network by a specific application running on a device.

Which tool should you use?

Answers:

- ***Protocol analyzer**
- Certifier
- Toner probe
- TDR
- Multimeter

Explanation:

Use a protocol analyzer (also called a packet sniffer) to examine network traffic. You can capture or filter packets from a specific device or packets that use a specific protocol.

Use a time-domain reflector (TDR) to measure the length of a cable or to identify the location of a fault in the cable.

A toner probe is two devices used together to trace the end of a wire from a known endpoint into the termination point in the wiring closet.

A cable certifier is a multi-function tool that verifies that a cable or an installation meets the requirements for a specific architectural implementation.

A multimeter is a device that tests various electrical properties, such as voltage, amps, and ohms.

q_prot_analyzers_sniffer_01_secp8

You want to know which protocols are being used on your network. You'd like to monitor network traffic and sort traffic by protocol.

Which tool should you use?

Answers:

- Port scanner
- ***Packet sniffer**
- IDS
- IPS
- Throughput tester

Explanation:

A packet sniffer is special software that captures (records) frames that are transmitted on a network. Use a packet sniffer to:

- Identify the types of traffic on a network.
- View the exchange of packets between communicating devices. For example, you can capture frames related to the domain name system (DNS) and view the exact exchange of packets for a specific name resolution request.
- Analyze packets sent to and from a specific device.
- View packet contents.

Use a port scanner to identify protocol ports that are opened in a firewall or active on a device. A port scanner checks individual systems, while a packet sniffer watches traffic on the network.

A throughput tester measures the amount of data that can be transferred through a network or processed by a device (such as the amount of data that can be retrieved from a disk in a specific period of time).

An IDS is a special network device that can detect attacks and suspicious activity. A passive IDS monitors, logs, and detects security breaches, but it takes no action to stop or prevent the attack. An active IDS (also called an intrusion protection system, or IPS) performs the functions of an IDS, but it can also react when security breaches occur.

q_prot_analyzers_sniffer_02_secp8

You are concerned about attacks directed against the firewall on your network. You would like to examine the content of individual frames sent to the firewall.

Which tool should you use?

Answers:

- ***Packet sniffer**
- Load tester
- Throughput tester
- Event log
- System log

Explanation:

A packet sniffer is special software that captures frames transmitted on the network. Use a packet sniffer to:

- View packet contents.
- Identify the types of traffic on a network.
- View the exchange of packets between communicating devices. For example, you can capture frames related to the domain name system and view the exact exchange of packets for a specific name resolution request.
- Analyze packets sent to and from a specific device.

A load tester simulates a load on a server or service.

A throughput tester measures the amount of data that can be transferred through a network or processed by a device (such as the amount of data that can be retrieved from a disk in a specific period of time).

System and event logs record what has happened on a device. They do not record individual frames or packets.

q_prot_analyzers_soar_secp8

Which of the following roles would be MOST likely to use a protocol analyzer to identify frames that might cause errors?

Answers:

- Network administrator
- Malicious hacker
- Standard user
- ***Security operations team**

Explanation:

The network security operations (SecOps) team can use a protocol analyzer during a vulnerability assessment. The protocol analyzer can help the SecOps team to:

- Identify frames that might cause errors. For example, the network administrator can:
  - Determine which flags are set in a TCP handshake.
  - Detect any malformed or fragmented packets. This would indicate that someone is trying to get around the firewall.
- Discover passwords and other sensitive data being sent in cleartext.
- Find any open network ports that should not be open.

A network administrator can use a protocol analyzer to assist in the management of the network and employee usage. However, a network administrator would not be the most likely to use a protocol analyzer to identify frames that might cause errors.

A malicious hacker could use a protocol analyzer to identify frames that might cause errors, but they most likely would not use it for that purpose.

A standard user should not be using a protocol analyzer on a network for any reason.

q_prot_analyzers_wireshark_secp8

You want to use a tool to see packets on a network, including the source and destination of each packet.

Which tool should you use?

Answers:

- ***Wireshark**
- OVAL
- Nessus
- nmap

Explanation:

A protocol analyzer, also called a packet sniffer, is special software that captures (records) frames that are transmitted on a network. A protocol analyzer is a passive device. It copies frames and allows you to view frame contents, but it does not allow you to capture, modify, and retransmit frames (activities that are used to perform an attack). Wireshark is a popular protocol analyzer.

The nmap command is a tool that performs ping scans (finding devices on the network) as well as port scans (looking for open ports on the network).

Nessus is a vulnerability-scanning tool. While a protocol analyzer looks at packets on the network, a vulnerability scanner looks for weaknesses in systems, including open ports, running services, and missing patches.

Open Vulnerability and Assessment Language (OVAL) is an international standard for testing, analyzing, and reporting a system's security vulnerabilities.

6.5 Analyzing Network Attacks

As you study this section, answer the following questions:

- In which type of attack does the hacker place themselves between two devices to intercept communications?
- What are common indicators of a DDoS attack?
- What is the usual result of a distributed denial-of-service attack?
- What is a reflected DDoS attack?
- What are some indicators of a DNS attack?

In this section, you will learn to:

- Analyze ARP poisoning.
- Poison ARP and analyze with Wireshark.
- Analyze DNS poisoning.
- Poison DNS.
- Analyze SYN flood.

- Perform and analyze a SYN flood.
- Examine DNS attacks.

The key terms for this section include:

Term	Definition
On-path attack	An attack where the threat actor makes an independent connection between two victims and is able to read and possibly modify traffic.
Credential replay	An attack that uses a captured authentication token to start an unauthorized session without having to discover the plaintext password for an account.
Distributed reflected DoS (DRDoS)	A malicious request to a legitimate server is created and sent as a link to the victim, so that a server-side flaw causes the malicious component to run on the target's browser.
Amplification attack	A type of reflected attack that targets weaknesses in specific application protocols to make the attack more effective at consuming target bandwidth. Amplification attacks exploit protocols that allow the attacker to manipulate the request in such a way that the target is forced to respond with a large amount of data.
DNS poisoning	An attack where a threat actor injects false resource records into a client or server cache to redirect a domain name to an IP address of the attacker's choosing.
Distributed denial-of-service (DDoS)	An attack that involves the use of infected Internet-connected computers and devices to disrupt the normal flow of traffic of a server or service by overwhelming the target with traffic.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	2.1 Compare and contrast common threat actors and motivations.
	2.1.3 - Motivations

6.5.1 Analyzing Network Attacks (Lesson Video)

Transcript:

In this lesson, we'll focus on various network attack techniques and indicators. A network attack is a general category for a number of strategies and techniques that threat actors use to either disrupt or gain access to systems via a network vector. Let's dive in.

We'll begin by discussing distributed denial-of-service, or DDoS, Attacks. A denial-of-service (DoS) attack is anything that reduces the availability of a resource.
It can target physical hardware, like servers and routers, or exploit software vulnerabilities to disrupt services.
Malware-based DoS attacks can even destroy file systems or overload hardware components like CPU, memory, storage, or network bandwidth.
DDoS attacks are a specific breed of DoS attacks. They're called "distributed" because they're launched from multiple sources simultaneously. Threat actors compromise machines and use them as handlers in a command-and-control network, forming a botnet. These botnets are then used to carry out DDoS attacks.
Assembling and managing a botnet large enough to overwhelm a network that has effective DDoS mitigation measures can be a costly endeavor. This has prompted threat actors to devise DDoS techniques that increase the effectiveness of each attack.
In a distributed reflected DoS, or DRDoS, attack, the threat actor spoofs the victim's IP address and attempts to open connections with multiple third-party servers. Those servers direct their SYN/ACK responses to the victim host. This rapidly consumes the victim's available bandwidth.
An amplification attack is a type of reflected attack that targets weaknesses in specific application protocols to make the attack more effective at consuming target bandwidth. Amplification attacks exploit protocols that allow the attacker to manipulate the request in such a way that the target is forced to respond with a large amount of data. Recognizing DDoS attacks is crucial, but it can be challenging.

Look for unexplained traffic spikes with no legitimate explanation. To mitigate these attacks, we often need high-availability services like load balancing and cluster services.
However, DDoS attacks often involve spoofed source addresses, making it challenging to stop them at the source.
Now, let's shift gears to on-path Attacks.
In on-path attacks, threat actors position themselves between two hosts, capturing, monitoring, and even modifying their communication. This means the hosts might not even realize they're being intercepted.
Another attack focuses on the domain name system. The domain name system, or DNS, resolves requests for named hosts and services to IP addresses. Name resolution is a critical addressing method on the internet and on private networks. There are many potential attacks against DNS.
On the public internet, attackers might use typosquatting to confuse victims with malicious sites.
DNS can also be exploited in DRDoS attacks or by hijacking public DNS servers.
If threat actors have access to the same network as the victim, they can use DNS-based on-path attacks. They respond to DNS queries with spoofed replies, often in conjunction with denial-of-service attacks on the victim's legitimate DNS server. In some cases, rogue DHCP servers might be used to redirect clients to DNS resolvers controlled by attackers.
Another DNS attack vector is DNS client cache poisoning. Here, attackers manipulate the HOSTS file, which is a text file containing a known name: IP address mapping. This cache is checked before DNS resolution is used. If this cache is poisoned, it can redirect traffic wherever the attacker chooses. Think of it as altering road signs to lead people astray.
DNS server cache poisoning aims at corrupting the DNS server's records. Attackers can perform DoS against the server holding authorized records and spoof replies to other name servers. DNS server cache poisoning can also involve making the victim DNS server respond to recursive queries with false records.
DNS can also be misused for command and control of remote access Trojans.
To detect DNS attacks, monitoring DNS event logs is crucial. Look out for unusual query types, suspicious IP address ranges, or spikes in DNS lookup failures.
Wireless attacks are security threats targeting wireless networks. Let's look at a few. A rogue access point is an unauthorized network access point connected to a network. It can be set up maliciously or accidentally. An evil twin is a rogue access point mimicking a legitimate one, often using similar SSID names to deceive users.
For example, a malicious user sets up an evil twin with the same SSID as a coffee shop's Wi-Fi, intercepting users' data when they unknowingly connect to it.
A wireless denial-of-service attack prevents clients from connecting to the legitimate access point.
This attack disrupts wireless networks by interfering with signals or targeting clients. Attackers can jam legitimate networks with rogue access points or send spoofed frames to disconnect clients.
The final network attack technique we'll look at in this lesson is a wireless replay attack. A replay attack is an attack where the threat actor intercepts some authentication data and reuses it to try to reestablish a session. A credential replay is an attack that uses a captured authentication token to start an unauthorized session without having to discover the plaintext password for an account.
Well, that's it for this lesson. In this lesson, we went over several network attack strategies. First, we looked at various denial-of-service attacks. We then reviewed on-path attacks. Next, we discussed DNS attacks. And we finished the lesson by looking at wireless attacks. Being familiar with the variety of ways networks can be attacked is one of the most critical aspects of cybersecurity.

6.5.2 Analyzing Network Attacks Facts

This lesson covers the following topics:

- Network attacks
- Distributed denial-of-service (DDoS) attacks
- On-path attacks
- Domain Name System (DNS) attacks

Network Attacks

A network attack is a general category for a number of strategies and techniques that threat actors use to either disrupt or gain access to systems via a network vector. Network attack analysis is usually informed by considering the place each attack type might have within an overall cyberattack lifecycle:

- Reconnaissance is where a threat actor uses scanning tools to learn about the network. Host discovery identifies which IP addresses are in use. Service discovery identifies which TCP or UDP ports are open on a given host. Fingerprinting identifies the application types and versions of the software operating each port and potentially the operating system running on the host and its device type. Rapid scanning generates a large amount of distinctive network traffic that can be detected and reported as an intrusion event. Still, it is very difficult to differentiate malicious scanning activity from non-malicious scanning activity.
- Credential harvesting is a type of reconnaissance where the threat actor attempts to learn passwords or cryptographic secrets that will allow them to obtain authenticated access to network systems.
- Denial-of-service (DoS) in a network context refers to attacks that cause hosts and services to become unavailable. This type of attack can be detected by monitoring tools that report when a host or service is not responding or is suffering from abnormally high volumes of requests. A DoS attack might be launched as an end in itself or to facilitate the success of other types of attacks.
- Weaponization, delivery, and breach refer to techniques that allow a threat actor to get access without having to authenticate. This typically involves various types of malicious code being directed at a vulnerable application host or service over the network or sending code concealed in file attachments and tricking a user into running it.
- Command and control (C2 or C&C), beaconing, and persistence refer to techniques and malicious code that allow a threat actor to operate a compromised host remotely and maintain access to it over a period of time. The threat actor has to disguise the incoming command and outgoing beaconing activity as part of the network's regular traffic, such as by using encrypted HTTPS connections. Detection of this type of activity usually depends on identifying anomalous connection endpoints, such as connections to IP addresses in countries that do not respect copyright or privacy laws. There can also be indicators on the compromised host, such as the malware itself and unauthorized startup items.
- Lateral movement, pivoting, and privilege escalation refer to techniques that allow the threat actor to move from host to host within a network or from one network segment to another and to obtain wider and higher permissions for systems and services across the network. These types of attacks are detected via anomalous account logins and privilege use. Still, detection usually depends on machine learning-backed software, as it is typically difficult to differentiate anomalous behavior from normal behavior.
- Data exfiltration refers to obtaining an information asset and copying it to the attacker's remote machine. Anomalous large data transfers might be an indicator of exfiltration, but a threat actor could perform the attack stealthily by only moving small amounts of data at any one time.

Note that stages in the lifecycle are iterative. For example, a threat actor might perform external reconnaissance and credential harvesting or breach to obtain an initial foothold. They might then perform reconnaissance and credential harvesting from the foothold to perform lateral movement and privilege escalation on internal hosts.

Distributed Denial-Of-Service (DDoS) Attacks

A denial-of-service (DoS) attack is anything that reduces the availability of a resource. DoS attacks can target physical hardware and infrastructure. A malware-based DoS attack might destroy a file system or engineer excessive CPU, memory, storage, or network bandwidth consumption.

A DoS attack can also exploit protocol or configuration weaknesses at different network layers. DoS attacks against network hosts and gateways are typically of a type called distributed DoS (DDoS). DDoS means that the attack is launched from multiple hosts simultaneously. Typically, a threat actor will compromise machines to use as handlers in a command and control network. The handlers are used to compromise thousands or millions of hosts with DDoS bot tools, forming a botnet.

Some types of DDoS attacks simply aim to consume network bandwidth, denying it to legitimate hosts by using overwhelming numbers of bots making ordinary requests. Others cause resource exhaustion on the victim host by bombarding them with requests, which consume CPU cycles and memory. This delays the processing of legitimate traffic and could potentially crash the host system completely. For example, a SYN flood attack works by withholding the client's ACK packet during TCP's three-way handshake. A server, router, or firewall can maintain a queue of pending connections recorded in its state table. When it does not receive an ACK packet from the client, it resends the SYN/ACK packet a set number of times before timing out the connection. The problem is that a server may only be able to manage a limited number of pending connections, which the DDoS attack quickly fills up. This means that the server is unable to respond to genuine traffic.

Reflected Attacks

Assembling and managing a botnet large enough to overwhelm a network that has effective DDoS mitigation measures can be a costly endeavor. This has prompted threat actors to devise DDoS techniques that increase the effectiveness of each attack. In a distributed reflected DoS (DRDoS) attack, the threat actor spoofs the victim's IP address and attempts to open connections with multiple third-party servers. Those servers direct their SYN/ACK responses to the victim host. This rapidly consumes the victim's available bandwidth.

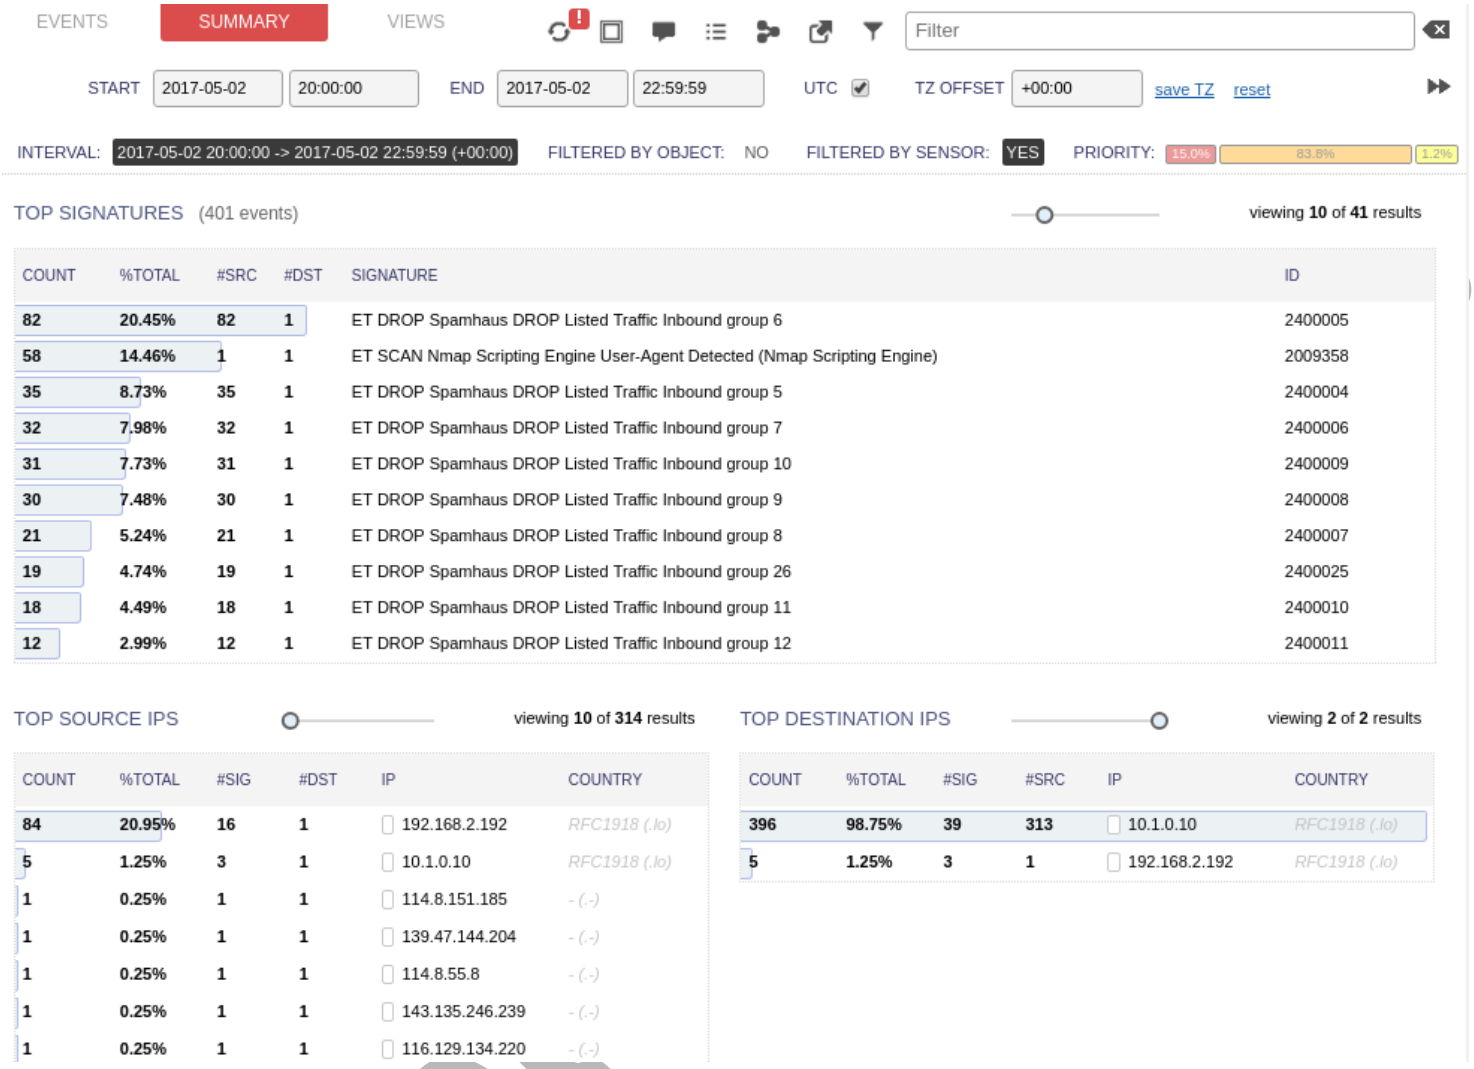
An asymmetric threat is one where the threat actor is able to perpetrate effective attacks despite having fewer resources than the victim.

Amplified Attacks

An amplification attack is a type of reflected attack that targets weaknesses in specific application protocols to make the attack more effective at consuming target bandwidth. Amplification attacks exploit protocols that allow the attacker to manipulate the request in such a way that the target is forced to respond with a large amount of data. Protocols commonly targeted include Domain Name System (DNS), N etwork T ime P rotocol (NTP), and C onnectionless L ightweight D irectory A ccess P rotocol (CLDAP). Another example of a particularly effective attack exploits the Memcached database caching system used by web servers.

DDoS Indicators

DDoS attacks can be diagnosed by traffic spikes that have no legitimate explanation. Still, they can usually only be mitigated by providing high-availability services, such as load balancing and cluster services. In some cases, a stateful firewall can detect a DDoS attack and automatically block the source. However, for many of the techniques used in DDoS attacks, the source addresses will be randomly spoofed or launched by bots, making it difficult to stop the attack at the source.

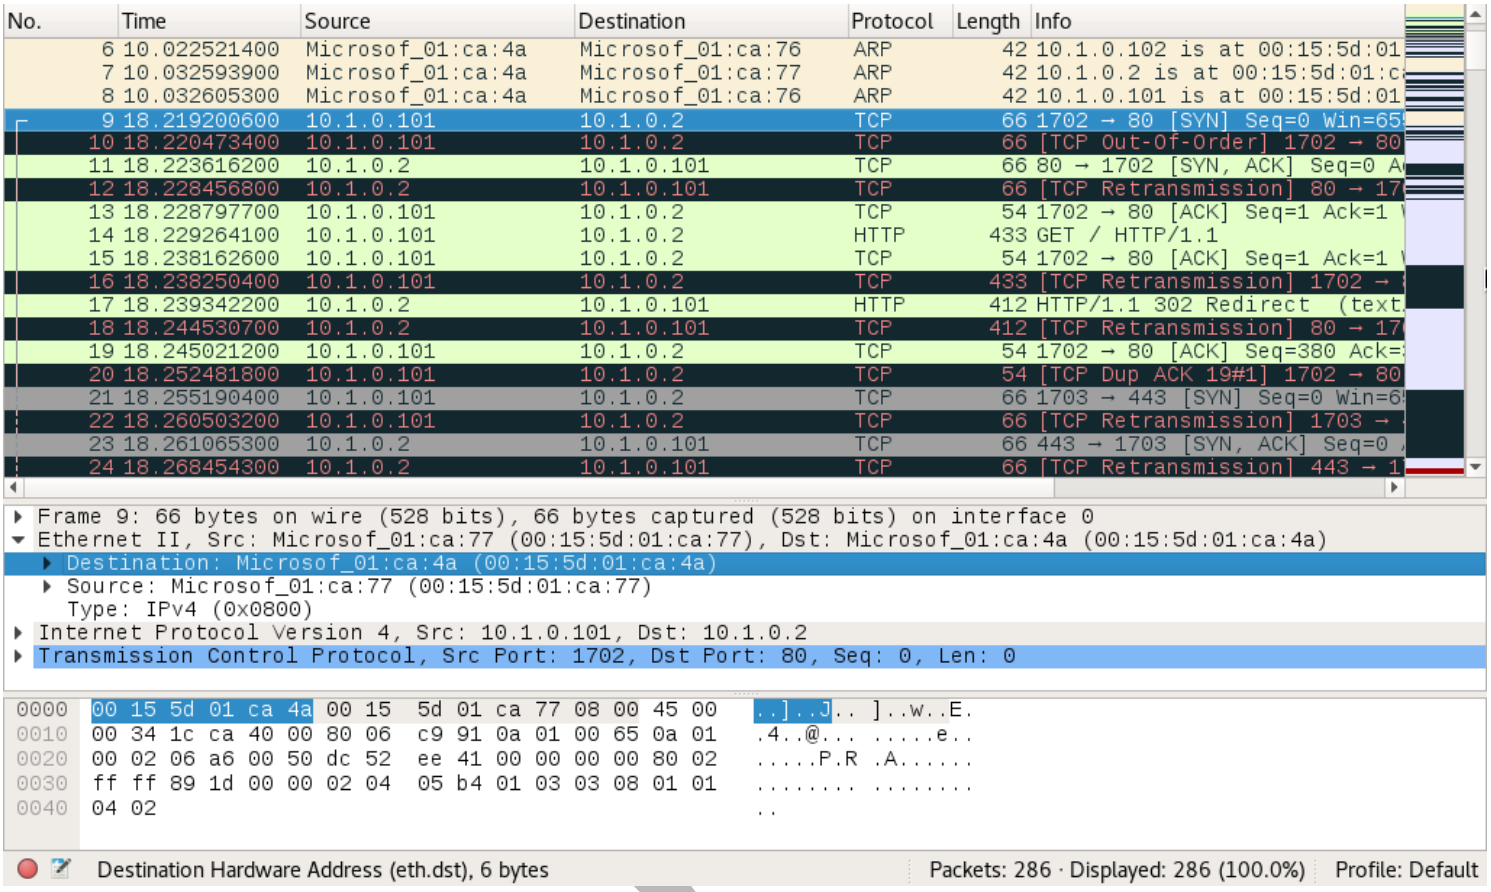


Dropping traffic from blocklisted IP ranges using Security Onion IDS. (Screenshot used with permission from Security Onion.)

On-Path Attacks

An on-path attack is where the threat actor gains a position between two hosts and transparently captures, monitors, and relays all communication between them. Because the threat actor relays the intercepted communications, the hosts might not be able to detect the presence of the threat actor. An on-path attack could also be used to covertly modify the traffic. For example, an on-path host could present a workstation with a spoofed website form to try to capture the user credential. This attack is also referred to as an on-path attack or as an adversary-in-the-middle (AitM) attack.

On-path attacks can be launched at any network layer. One infamous example attacks the way layer 2 forwarding works on local segments. The Address Resolution Protocol (ARP) identifies the MAC address of a host on the local segment that owns an IPv4 address. An ARP poisoning attack uses a packet crafter, such as Ettercap, to broadcast unsolicited ARP reply packets. Because ARP has no security mechanism, the receiving devices trust this communication and update their MAC:IP address cache table with the spoofed address.



Packet capture opened in Wireshark showing ARP poisoning. (Screenshot used with permission from wireshark.org.)

This screenshot shows packets captured during a typical ARP poisoning attack:

- In frames 6–8, the attacking machine (with MAC address ending :4a) directs gratuitous ARP replies at other hosts (:76 and :77), claiming to have the IP addresses .2 and .102. This pattern of gratuitous ARP traffic is an indicator of the attack.
- In frame 9, the .101/:77 host tries to send a packet to the .2 host, but it is received by the attacking host (with the destination MAC :4a).
- In frame 10, the attacking host re-transmits frame 9 to the actual .2 host. Wireshark colors the frame black and red to highlight the re-transmission.
- In frames 11 and 12, you can see the reply from .2, received by the attacking host in frame 11 and re-transmitted to the legitimate host in frame 12.

The usual target will be the subnet's default gateway (the router that accesses other networks). If the ARP poisoning attack is successful, all traffic destined for remote networks will be received by the attacker, implementing an on-path attack.

Domain Name System (DNS) Attacks

The Domain Name System (DNS) resolves requests for named hosts and services to IP addresses. Name resolution is a critical addressing method on the internet and private networks. There are many potential attacks against DNS. On the public internet, attacks might use typosquatting techniques to cause victims to confuse malicious sites with legitimate ones. DNS can be exploited in a DRDoS attack. Threat actors can also directly target public DNS services as a means of performing DoS against a website or cloud resource. Finally, a threat actor might be able to hijack a public DNS server and insert spoofed

records, directing victims to rogue websites.

On a private network, a DNS attack is likely to mean some sort of DNS poisoning. DNS poisoning compromises the process by which clients query name servers to locate the IP address for a domain name. There are several ways that a DNS poisoning attack can be perpetrated.

DNS-Based On-Path Attacks

If the threat actor has access to the same local network as the victim, the attacker can use ARP poisoning to respond to DNS queries from the victim with spoofed replies. This might be combined with a denial-of-service attack on the victim's legitimate DNS server. A rogue DHCP could be used to configure clients with the address of a DNS resolver controlled by the threat actor.

DNS Client Cache Poisoning

Before DNS was developed in the 1980s, name resolution took place using a text file named HOSTS. Each name:IP address mapping was recorded in this file, and systems administrators had to download the latest copy and install it on each internet client or server manually. Even though most name resolution now functions through DNS, the HOSTS file is still present, and most operating systems check the file before using DNS. Its contents are loaded into a cache of known name:IP mappings and the client only contacts a DNS server if the name is not cached. Therefore, if an attacker is able to place a false name:IP address mapping in the HOSTS file and effectively poison the DNS cache, they will be able to redirect traffic. The HOSTS file requires administrator access to modify. In UNIX and Linux systems, it is stored as /etc/hosts, while in Windows, it is placed in %SystemRoot%\System32\Drivers\etc\hosts. The presence of suspect entries in the HOSTS file indicates that the machine has been compromised.

DNS Server Cache Poisoning

DNS server cache poisoning aims to corrupt the records held by the DNS server itself. This can be accomplished by performing DoS against the server that holds the authorized records for the domain and then spoofing replies to requests from other name servers. Another attack involves getting the victim name server to respond to a recursive query from the attacking host. A recursive query compels the DNS server to query the authoritative server for the answer on behalf of the client. The attacker's DNS, masquerading as the authoritative name server, responds with the answer to the query but also includes a lot of false domain:IP mappings for other domains that the victim DNS accepts as genuine. The nslookup or dig tool can be used to query the name records and cached records held by a server to discover whether any false records have been inserted.

DNS Attack Indicators

A DNS server may log an event each time it handles a request to convert between a domain name and an IP address. DNS event logs can hold a variety of information that may supply useful security intelligence and attack indicators, such as:

- The types of queries a host has made to DNS.
- Hosts that are in communication with suspicious IP address ranges or domains.
- Statistical anomalies, such as spikes or consistently large numbers of DNS lookup failures, may point to computers infected with malware, misconfigured, or running obsolete or faulty applications.

DNS is also a popular choice for implementing command & control (C&C) of remote access Trojans. It can be used as a means of covertly exfiltrating data from a private network.

6.5.3 Analyzing ARP Poisoning (Demo Video)

Transcript:

On-path attacks are very popular because they're so productive. When a hacker puts themselves between a victim and the machine they're connecting to, they can capture traffic, delete traffic, inject their own traffic, spoof DNS, and capture passwords. Imagine the damage that can happen if someone captures important documents and leaks their contents or steals the information. In this demo, we're going to illustrate how to capture a password with a on-path attack so that, as a security analyst, you can take countermeasures to protect your organization.

So, let's get started. First, I'm going to scan my subnet to see what hosts are connect and identify my router. Inside this terminal on my Kali Linux machine, I can type in "nmap 10.10.10.0/24' and press Enter. This is going to scan my 10.10.10.0 subnet. It finished pretty quickly.
Now let's scroll up and see what we found. Up there, I found my router, router.CorpNet.xyz with an IP address of 10.10.10.1. We need to remember this information for later.
Here, I have another device on the CorpNet domain with an IP of 10.10.10.169.
I'll scroll down a bit. This device, here, is the one I'm most interested in, PC-12 with an IP ending in 195. This is the machine that's going to be my victim machine and the one that I'm going to try to capture passwords from. Let' go ahead and close this terminal.
Now I want to open Ettercap. Ettercap comes in both a GUI and a command line interface. It's pre-installed as part of Kali Linux, so we don't have to install or download anything. To open Ettercap, I go up here, to Applications, go down to Sniffing & Spoofing, and then, over to the right, find Ettercap. The Ettercap GUI will appear. And from there, I'll come up to the Sniff tab and select Unified Sniffing. That will launch a dialog box, where I'm prompted to select my Network interface. I only have two options. Depending on your system, you may have multiple interfaces such as a WLAN interface or multiple LAN interfaces. I'm going to leave it with eth0 and click OK.
Now let's scan our subnet for hosts. As you'll recall from our NMAP scan, I had three hosts. I'll come up to the Hosts tab, come down to Scan for hosts, and select it. Ettercap starts scanning the subnet for hosts. Down here, you can see that it scanned 255 hosts and found three.
Now I want to list these hosts, so I'll go up to the Host tab. This time, we'll come down to the Hosts list and select it. Here, we can see our three hosts. Remember that this 10.10.10.1 was our router, and our victim machine is the one that ended with 195.
Let's go back up here, to the router, and select it. Down here, I want to select Add to Target 1. Now I'll come back up and select the host ending in 195. And then we'll go back down. This time, we'll select Add to Target 2.
So, what am I doing here? This is where I'm going to insert myself between the router and the victim. To do that, I'm going to go up to the Mitm tab, come down a bit, and select ARP poisoning. In this new dialog box, I want to check the box that says "Sniff remote connections" and click OK.
All right. Now, I'll come up to Start and select Start sniffing. I should have stopped sniffing earlier, but it'll still work fine. Now Ettercap is sniffing our traffic between our victim and the router. We just need to wait for our victim to try to log into a website. Let's jump over to our Windows machine, the one with the IP that ended with 195.
All right. I'm over on the Windows machine now, and I've brought up this website. It's a Moodle site, a popular learning management platform used by many educational organizations. I've hidden the web address, but it's an HTTP site, not HTTPS. Just to confirm that we're on the correct machine, I'll quickly open a command prompt and do an ipconfig to verify the IP address. It's the correct machine. It looks good. I'll close this window.
Let's go ahead and log in with some credentials. I'll just type in the word 'teacher', and I'll use 'letmein' for the password. I'll click Log in. It tells me that I have an invalid login, and it wants me to try logging in again. That's totally okay for what we're demonstrating. Let's jump back over to our Kali Linux machine and see what's happening with Ettercap.
Okay. I'm back on Kali, and here's Ettercap. Down here, at the bottom, you can see that when I attempted to log in, Ettercap captured the username "teacher" and the password "letmein". Of course, this isn't the correct username and password, but Ettercap would capture whatever was entered, and we assume that the user would eventually enter their correct credentials.
The important thing to remember here is that this method does not work with HTTPS. But most users have a habit of using the same credentials for multiple sites. So, once you get the credentials to one site, you'll likely have credentials for multiple sites.
That's it for this demo. In this demo, we used Ettercap to create a on-path attack with ARP poisoning to capture login credentials through a website.

6.5.4 Poison ARP and Analyze with Wireshark (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You believe a hacker has penetrated your network and is using ARP poisoning to infiltrate it.

In this lab, your task is to discover whether ARP poisoning is taking place as follows:

- Use Wireshark to capture packets on the *enp2s0* interface for five seconds.
- Analyze the Wireshark packets to determine whether ARP poisoning is taking place.
- Use the **192.168.0.2** IP address to help make your determination.
- Answer the questions.

Explanation

Complete this lab as follows:

1. Use Wireshark to capture packets on *enp2s0* .
    a. From the Favorites bar, select **Wireshark** .
    b. Maximize the window for better viewing.
    c. Under Capture, select **enp2s0** .
    d. From the menu bar, select the ***blue fin*** to begin a Wireshark capture.
    e. After capturing packets for five seconds, select the ***red box*** to stop the Wireshark capture.
2. Filter for only ARP packets.
    a. In the *Apply a display filter* field, type **arp** and press **Enter** to only show ARP packets.
    b. In the Info column, look for the lines containing the **192.168.0.2** IP address.
3. Answer the questions.
    a. From the top right, select **Answer Questions** .
    b. Answer Questions 1 and 2.
    c. Select **Score Lab** .

6.5.5 Analyzing DNS Poisoning (Demo Video)

Transcript:

DNS Spoofing, sometimes referred to as DNS cache poisoning, is an attack where a rogue device directs DNS requests on a network. This basically means that an attacker manipulates the DNS to redirect DNS traffic. This type of attack is very difficult to detect, which makes it quite dangerous. In this demo, we're going to redirect DNS to our Kali Linux machine, spoof the DNS, and point to a web page I've set up.

For this demo, we're going to use Kali Linux with Ettercap. Ettercap has a GUI interface. That's what we're going to use. But we need to do a few other things before we get started.
I'm going to open up a terminal here, on Kali Linux. We need to check the etter.config file. The easiest way to find this file is to just type 'locate etter.conf' and press Enter. The path I'm interested is this one, right up here. I'm going to use the program Leafpad to open the file. We'll type in 'leafpad /etc/ettercap/etter.conf' and press Enter. And Leafpad opens my file.
Now we need to edit these two lines of code, uid and gid. I need to change both of these values to zero.
After that, we need to scroll down a bit, to where it says Linux. Right under there, we want to find the iptables. These two lines are commented out with the pound sign (#). Just delete the two pound signs from these lines of code. There's one here and one here. So, now that we've done that, we'll save our file and close this window.
Now that we're done with that, we need to edit our etter.dns file. I'm back in the terminal. Once again, to find this file, I can just type in 'locate etter.dns'. And, just like before, I'll use Leafpad to open it by typing 'leafpad etter.dns'. The file opens up.
I need to add a line to this host file. I'll scroll down until I see these few lines with Microsoft in them. Right above those lines, I want to add this line, here: '* A 10.10.10.197'. By doing this, we're telling all of the DNS traffic on the network to go to this IP address, which is actually my Kali Linux system's IP address. The Microsoft lines are not commented out by

default, but I went ahead and put pound signs (#) in front of them. We don't want to redirect their DNS. Before I exit, I want to go up and save the file.
All right. We have some more editing to do here. Now I need to edit my index.html file. Since we're spoofing the DNS and redirecting traffic to our Kali system, I need to give the users something to see, so I'll edit the index page.
To get to that file, I'll come up to Places and come down here, to Computer. From there, I need to find the folder called var and open it. Within var, I'll go over to the www folder, then to the html folder. I've already made some changes in here. One of the things I did was copy my index.html file and rename it. Let's open this old file and see what the contents look like.
Okay, our file is open. And, like I said, by default, this is our index.html file on this Linux system. I didn't want to modify the original in case I need to restore it later, so I made this copy. Now let's close this one and open up the modified copy that I created. Once again, I'll use Leafpad to do that. Here, you can see I made a very simple landing page for our victims. It says, "You have been denied access to this site. Nice try!" I've already saved it, so I'll go ahead and close this file.
We're done editing files. Now we can go to Applications > Sniffing & Spoofing > Ettercap. Ettercap opens for us. And the first thing we need to do here is come up to the Sniff tab and select Unified Sniffing. A dialog box opens up. We want to select our network adapter. In our case, that's eth0. Click OK. We actually want to come back up to Start and select Stop Sniffing because we're not quite ready yet.
We're going to go over to the Hosts tab and select the Scan for Hosts selection. Ettercap will do its thing and start scanning. You can see, down here, that we found three hosts.
Now let's go up to Hosts again. This time, select the Hosts list. And down here, you can see the three hosts. Previously, I ran NMAP and figured out that this top host is my router, and this bottom host is my victim machine, the one I want to attack so that anytime this machine goes to a website, the DNS is going to point them to my Kali Linux machine's IP address. So, while my victim IP is selected, I'll come down here and click Add to Target 1.
Now we'll go to Plugins > Manage the plugins and select the dns_spoof option. Now, if we look down here, in the lower pane, you can see it says, "Activating dns_spoof plugin..."
All right, we're almost done. I need to come up to the MITM tab and select ARP poisoning. When the dialog opens up, we need to check the box for Sniff remote connections and then click OK.
We need to start the Apache web service on the Kali machine to actually make it into a web server. I do that by opening up a terminal and typing in 'service apache2 start'. Nothing really exciting happens, but this command starts the Apache service for us.
That wraps up our steps on this Kali system. Now we need to see what happens when our victim tries to surf the web. We'll do that from a Windows machine.
All right. I'm on a Windows machine now. I'll go to a command prompt to check our IP address. I'll type in 'ipconfig', and we can confirm that the IP ends with 195, so this is the right machine. I'll close this window.
Down here, I'll launch Google Chrome, and I'll type in 'www.testout.com'. When the page launches, it takes me to the index.html page on my Kali Linux system and displays the message we typed. That confirms that our DNS has been spoofed and redirected.
That's it for this demo. In this demo, we configured our Kali Linux machine to redirect DNS requests and send the traffic to our modified index.html page. We discussed how we had to edit the files to make this happen and how to configure Ettercap to perform the DNS spoof.

6.5.6 Poison DNS (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You want to spoof the DNS to redirect traffic as part of a man-in-the-middle attack.

In this lab, your task is to:

- (Optional) From the **Exec** computer, access **rmksupplies.com** and verify that site can be accessed.
- From the Linux **Support** computer, use Ettercap to begin sniffing and scanning for hosts.
- Configure the **Exec** computer (192.168.0.30) as the target 1 machine.
- Initiate DNS spoofing.
- From the **Exec** computer, access **rmksupplies.com** and verify that it has been redirected to a different site.

Explanation

Complete this lab as follows:

1. From the Support computer, use Ettercap to begin sniffing and scanning for hosts.
    a. From the Favorites bar, select **Ettercap** .
    b. Select **Sniff** > **Unified sniffing** .
    c. From the Network Interface drop-down menu, select **enp2s0** .
    d. Select **OK** .
    e. Select **Hosts** > **Scan for hosts** .
2. Configure the Exec computer (192.168.0.30) as the target 1 machine.
    a. Select **Hosts** > **Host list** .
    b. Under IP Address, select **192.168.0.30** .
    c. Select **Add to Target 1** to assign it as the target.
3. Initiate DNS spoofing.
    a. Select **Plugins** > **Manage the plugins** .
    b. Select the **Plugins** tab.
    c. Double-click **dns_spoof** to activate it.
    d. Select **Mitm** > **ARP poisoning** .
    e. Select **Sniff remote connections** and then select **OK** .
4. From the Exec computer, access **rmksupplies.com** .
    a. From the top left, select **Floor 1 Overview** .
    b. Under Executive Office, select **Exec** .
    c. From the taskbar, select **Google Chrome** .
    d. In the URL field, type **rmksupplies.com** and then press **Enter** .
    Notice that the page was redirected to RUS Office Supplies despite the web address staying the same.

6.5.7 Analyzing a SYN Flood (Demo Video)

Transcript:

We've already talked about the three-way handshake, but let's quickly review it again. A three-way handshake starts when a client sends a connection request to a server, saying, "Let's connect." This is called a SYN message. The server acknowledges this request by sending a SYN-ACK message back to the client, saying, "Okay, I'll talk to you." Then the client sends back an ACK message, saying, "Great, we're talking." This is a three-way handshake.

When we're doing a SYN Flood, we're doing only part of this process. The attacker, or the client, doesn't respond back to the final ACK message. The server sits and waits with a half-open connection that's never completed, denying others communication with the server in the meantime. Another method is to spoof the IP address so the server responds to the spoofed IP address, never getting any response.
I'm going to demonstrate how all this works.
First, we need to choose a victim. I've already identified the IP address of my victim on my Kali Linux system, and I've run Zenmap against it. I scanned for all open ports from 0 to 65535. Here, you can see that we have all these ports. We're going to attack port 135. I'll minimize Zenmap for now.
To get an idea of what happens during this attack, let's open up the victim machine. It's a Windows 10 machine, and I've installed Wireshark on it. I'm going to go ahead and open Wireshark by clicking on the shark fin. We're doing this to see what happens when this machine is attacked.
I'm also going to come open Task Manager. We need the Performance tab. You can see my CPU is relaxed. We had a spike here, probably when we opened Wireshark. Down here, we really have no Ethernet activity. I actually need to go back over to Wireshark and click the shark fin to start sniffing traffic. I'll just leave for now and go back to Kali Linux.
I'm in Kali Linux, and we're going to use Metasploit for this attack. First, I'll open a terminal here. After it opens, I want to start the database. The Kali Linux Network Services Policy states that no network services, including database services, will run on boot by default, so we need to get the database going in order to get Metasploit up and running with database

support. From the terminal, we'll type 'service postgresql start' and press Enter. This starts the database that we'll need. A lot of times, I'll forget to do this, and you'll get an error letting you know it can't connect to the database.
All right. Now, let's start Metasploit. Type in 'msfconsole' and press Enter. This sometimes takes a few minutes to get started, so be patient. I'll adjust the terminal window and clear the screen.
Now, with Metasploit up and running, I want to search for SYN flood. I'll type in 'search synflood' and press Enter. And I get a matching module.
This is easy because there's only one module listed, so that's the one we're going to use. I'll use that module by copying this part, here. We'll type in 'use', paste in auxiliary/dos/tcp/synflood, and press Enter.
Now you can see that it loaded that module here, in red. We want to see the options for using this, so let's type 'show options'.
Okay. There are a few things we need to do here. We need to configure the remote host, shown here. I also want to configure the remote port. If you remember from our Zenmap scan, that's going to be port 135. I'm also going to spoof my IP address, down here. Okay. Let's configure these.
I'll start with the remote target. I'll type in 'set RHOST 10.10.10.195' and press Enter. Let's set the remote port, 'set RPORT 135', and press Enter.
Next, let's set the spoofed IP address by typing 'set SHOST 10.10.10.50'. I just randomly picked that 50, but I do know that this IP isn't used on my network.
Now, let's look at our options again by typing 'show options'. We have everything in there, and it's just the way we planned, so it looks like we're ready to attack. I'll type 'clear' to clean up the screen.
To run the exploit and start our SYN Flood, we just type in 'exploit' and press Enter. It says, "Hey, I'm SYN flooding 10.10.10.195 on port 135." Well, to be sure, let's jump back over to our Windows 10, the victim, and see what's going on.
I'm on the Windows 10 machine. First, let's look at Wireshark. I have a ton of traffic going from 10.50 to 10.195. Over here, you can see that SYN requests are happening. I'm going to stop sniffing here. Now let's highlight one of these. If I look in the lower pane, I can see one thing, the source's MAC address. It ends in 1c. That can help me determine the attacker's real IP address, since the MAC isn't spoofed. Now let's look at Task Manger.
As you recall, we looked at the CPU and Ethernet usage here. You can see that my CPU is a little higher than what it was previously; but it's not as high as I would have guessed. Also, if you look at the Ethernet, you can see that it's really busy. Remember, that's an attack from just one machine. Imagine if it were coming from 10 machines or hundreds of machines. It wouldn't take much to overwhelm this system.
So, how do you stop SYN floods from happening? There are several methods. Admins used to block the port of the incoming SYN requests, but that didn't work very well. Now, admins can use SYN cookies, RST cookies, filtering, and Microblocks to mitigate SYN flood attacks, as well as other methods.
That's it for this demo. In this demo, we started by reviewing the three-way TCP handshake. We discussed how a SYN flood begins with an incomplete handshake, leaving the server sitting and waiting. We performed a SYN flood using Metasploit. We viewed Wireshark and our performance on the victim machine to analyze the attack's effect. We ended by talking about a few of the countermeasures that help prevent SYN flooding.

6.5.8 Analyze a SYN Flood Attack (Simulation)

Scenario

You are the CorpNet IT administrator. Your support team says that CorpNet's customers are unable to browse to the public-facing web server. You suspect it might be under a denial-of-service attack, possibly a TCP-SYN flood attack. Your www_stage computer is on the same network segment as your web server, so you should use this computer to investigate the problem.

In this lab, your task is to:

- Capture packets from the network segment on **www_stage** using Wireshark.
  - Use the **enp2s0** interface.
- Analyze the attack using the following filters:
  - **tcp.flags.syn==1 and tcp.flags.ack==1**
  - **tcp.flags.syn==1 and tcp.flags.ack==0**
- Answer the question.

Explanation

Complete this lab as follows:

1. Using Wireshark, only capture packets containing both the SYN flag and ACK flags.
    a. From the Favorites bar, select **Wireshark** .
    b. Under Capture, select **enp2s0** .
    c. From the menu, select the ***blue fin*** to begin the capture.
    d. In the *Apply a display filter* field, type **tcp.flags.syn==1 and tcp.flags.ack==1** and press **Enter** to filter Wireshark to display only those packets with the SYN flag and ACK flag. You may have to wait up to a minute before any SYN-ACK packets are captured and displayed.
    e. Select the **red square** to stop the capture.
2. Change the filter to only display packets with the SYN flag.
    a. In the *Apply a display filter* field, change the tcp.flags.ack ending from the number **1** to the number **0** and press **Enter** .
    Notice that there is a flood of SYN packets being sent to 128.28.1.1 (www.corpnet.local) that are not being acknowledged.
    b. From the top right, select **Answer Questions** .
    c. Answer the question.
    d. Select **Score Lab** .

6.5.9 Examining DNS Attacks (Demo Video)

Transcript:

In this demo, we're going to look at a few ways an attacker may use the DNS system to get information about the computers in an organization, and also to compromise a machine and get access to information.

Let's first look at doing reconnaissance using DNS servers. One way this can be done is with the nslookup command.
You see that I have a PowerShell command prompt window open here, and if you just type nslookup, that will put you into this utility. nslookup is used to troubleshoot DNS server settings.
You can see here that the DNS server that I'll be using is this one. It's the default one that I have configured for my machine here. When a computer wants to resolve a name, the first thing it does is look into a special file called a host file.
We'll talk more about that later, but essentially the host file can contain mappings between domain names and specific IP addresses. If it's not in the host file, then an operating system checks its DNS cache.
If the mapping is in there, then it uses the IP address that it finds. If not, it goes out and does the name resolution with the DNS server that's configured.
In this case, nslookup simply allows us to do those queries by passing the cache that might be on a local operating system.
So, if we want to, here, we can simply type in the name that we want to resolve like google.com, and it will go out and resolve that. My DNS server here goes out and says, I don't know what IP address that is associated with.
And then it issues the query to the resolver that it's pointing to. And you see here the IP address of www.google.com. Of course, we can try other ones like testout.com and others in you'll see that the resolution occurs appropriately.
For this demo, I've set up a domain that we can use to see how a few vulnerabilities work.
One vulnerability that exists with DNS servers is the ability to find out all the domain information associated with a particular name. One way we can do that is using the list command.
To do that, we type ls; we specify the domain that we want using the -d flag; and then we can say ajptech.net. This will tell us all of the computers that are associated with the ajptech domain.
If you do that, you see that we have a full list of all the machines.
Now, this is just a test environment. I've just listed a few servers, etc.
You can imagine in an organization that has hundreds of computers, this provides very nice information to know which IP addresses we should spend time attacking, based on these records.

This is referred to as a zone transfer, and we need to make sure that our DNS servers in our organization don't allow zone transfers to just anyone.
They're useful because you don't want just a single server, and so you want to share those records with other secondary zones, but you need to restrict who is allowed to do those zone transfers.
Let's take a look at that, inside of Windows Server 2019. You see here I have launched the DNS manager on the server. If you haven't installed that role before, it's super simple to do, and you do so before configuring these different zones.
Let's go ahead and look at some of the properties that you might want to set.
The one that's of most interest to us right now is this Zone Transfers tab. This basically specifies who is allowed to gather all those records at once, and you can see here that we have 'To any server'.
We could come in and just say, 'No zone transfers are allowed.' But as I explained a minute ago, that's useful, because if this is the primary zone for that domain name, then you want to have a secondary zone.
You don't want a single point of failure here, and so you want to be able to allow zone transfers.
You can only allow servers in the Name Servers tab, which is nice because usually you set those up specific to a domain, and that would be anything that's listed here, or you can restrict it to a specific IP address.
Let's go ahead and apply those settings. Let's say that we're going to only allow the following servers, and I'll just put in a fake IP address here right now. It won't resolve right now, but that's okay. But it will restrict those zone transfers.
Let's go ahead and switch back over to our PowerShell window, and let's try that same command. You can see now that it says it has refused transferring all that information from the zone--perfect.
Now when people are doing reconnaissance, they won't be able to see everything that we have in that zone.
However, the domain name server continues to work, so I can say server1, and you can see that that name resolution continues to work. So, make sure you secure your zone transfers.
Today, restricting zone transfers is commonplace; in fact, it's the default of many operating systems, and it's the best practice everybody should have. If your DNS server isn't configured that way, you want to make sure that you take care of that. Now let's move on to a couple of other concepts.
There are many different DNS attacks, such as distributor reflection, denial of service attacks, cache poisoning, TCP send floods, and others.
Let me just briefly explain one of these to give you a flavor.
A distributor reflection denial of service attack occurs when several DNS queries are sent to a DNS server that has an open resolver, and that DNS server responds to the spoofed address with a large payload.
The key to the attack is that the attacker only has to send a small packet of information to the DNS server, and then the DNS server sends a large response, but that response doesn't go back to the attacker; it sends it to the target that the attacker listed, using a spoofed source IP address.
In short, the attacker uses the DNS to create a denial of service attack against the third party. In this case, you need to make sure that you don't have any open resolvers.
An open resolver is essentially a DNS server that's willing to resolve names for third parties.
Usually you protect this in a couple of different ways--either restricting the DNS requests that come into your DNS server, that is, you don't allow outside requests; or simply not having any forwarding capabilities associated with your DNS server, and making sure that recursion is disabled on your DNS server.
Let me show you that setting quickly here. If you come to your server, you'll see the properties of the server itself. We are in the zone from before. We're going to go over here to the Advanced tab.
You want to make sure that this option is set, so that you disable the recursion. That, of course, disables the forwarders as indicated there. I'll say OK there.
Then I'll come over to the Forwarders tab here. You can see that I'm set up, but it's not using those anymore. The downside of this is we need to use a different DNS server in order to do our name resolution.
This server now can only do name resolution for the domains that are on it, but that's okay. That's best practice. You definitely don't want to be susceptible to those amplification attacks that I just explained.
Let's come back here to our PowerShell prompt and get out of the nslookup command.
Let me show you a couple of other things. I'll go ahead and clear the screen, as well.
A minute ago, I explained that when name resolution needs to occur on an operating system, it first checks the set host file, and then it goes to cache, sees what's in cache and uses that if there is something that's associated with that name, and then it goes and does the name resolution using the DNS system.
Let's go ahead and take a look at that cache.
But before we do so, we need to make sure that we have something in cache. I'll simply go ahead and try to ping google.com. You can see that I get a response.
Now, to see what's in cache, you simply say ipconfig /displaydns. You can see that I have several different entries in there.

I have some of those entries because I have a browser running on my system, and it's already resolved some names.
Let's go ahead and try to clear that out. To clear out your cache, you type ipconfig /flushdns.
Let's ping google.com, and then let's go ahead and see if we can see just those name resolutions.
You can see here there is only one record now when we display the dns cache.
So, this cache constantly keeps track of what's been resolved previously so it doesn't have to invoke the DNS system for every single request if it already knows that information. It saves time.
Each of these records also has a time to live, as you can see there, and so they're constantly refreshing as the system is being used.
One mistake that some people come across when they're trying to resolve DNS issues is they forget to clear out their cache.
They hit a site that's in cache, they make some changes, and they don't realize that it's actually pulling it out of cache instead of going on. I want to make sure you're aware of how cache works.
Now what if we could poison the cache or insert a record in there that wasn't legitimate, that came from another source?
This is a little bit harder to architect, but if we could specify a different IP address for the name server, the DNS server, we could pull records from it. It would be saved in the cache or locally, and then subsequent resolutions would pull the IP address out of the cache.
Indeed, that's one attack that individuals use when exploiting the DNS system. We're not going to show that to you today, but I want to show you one other concept before we wrap up this demo, and that has to do with the host file that I mentioned a few minutes ago.
This is the host file I mentioned a minute ago, and you can see that it's located in Windows System32\drivers\etc\hosts.
In this file, you can include specific mappings between a domain name and an IP address.
Before there was this DNS system, this file was distributed to all the computers on the internet, and so there's just a huge file of these mappings so that you wouldn't have to remember the specific IP addresses.
Thankfully, the DNS system came along, making our lives a lot easier and being allowed to update, but this is still in place. And as I mentioned, it gets checked before the OS resolver cache, before going out to the DNS system to resolve domain names.
You can see an example of how you can use this. But before I put in an example, let me show you a legitimate site so that you can see how this works. Let's go to cat-bounce.com, just a random site.
You can see that there's something out there. If we want to redirect individuals, instead of them going to this site to a different site, we can go into the host file and add a mapping that we're interested in.
You can see that we put the IP address first, and then the domain name. So, I know that the duckduckgo server is at the following address, and then I can simply put www.cat-bounce.com, and I'll save that.
Recent browsers have incorporated a DNS cache inside of the browser itself.
They do this because it gives them a competitive advantage to go ahead and resolve those domain names ahead of time, the minute that they show up on a page and that you might potentially click on.
Lets open an incognito window to bypass the cache.
If we go to www.cat-bounce.com, you see that it forwards on duckduckgo.com. I hope you can see how dangerous this could be. This is considered host file manipulation.
However, an attacker could simply keep that in place and use. An innocent individual wouldn't have any idea that you weren't on the legitimate site.
Consider banking sites or corporate sites, anywhere where sensitive information might be shared. An attacker can get access to this host file, present what looks to be a legitimate website, and then siphon off data as you use it.
It's also good to know that you can use host file to block malicious information, if you are a systems administrator.
This is a common site. It looks a little dated, but the information is pretty good on it. You can come and download a specific host file to block out a bunch of bad or malicious sites.
The IP address you see is a null IP address. In other words, if we added this to our host file and you went there, it simply wouldn't go anywhere.
One thing to note, you'll need to have administrator rights to adjust the host file.
That's it for this demo. In this demo, we've look at a few ways that an attacker can use the DNS system to get out information about computers in the organization and to compromise a machine and eventually grab sensitive information.
We've looked at the nslookup command. We've looked at zone transfers. We've looked at securing the open resolvers.
And we've looked at the host file and clearing cache.
It's really important that you protect your DNS servers and make sure that you aren't taken advantage of in that way.

6.5.10 Malicious Code (Lesson Video)

Transcript:

Malicious software is perhaps the most dangerous threat to any computing device. It's so prevalent that most people combine the words â€˜malicious software' and just call it malware. It isn't always coded using advanced programming languages. In fact, Python is one of the common languages used to design malicious codes. Sometimes a simple script can exploit built-in OS features such as shells. Even application features like macros can be used to develop and execute malicious codes. In this lesson, we'll look at how malicious code and scripts are designed and executed.

Python is one of the most popular programming languages. It was first released in 1999. It's designed to be easy to learn and read, and it works with most operating systems, including Windows, MacOS, and Linux.
Aside from being easy to read and understand, Python can take advantage of a massive amount of open-source Python packages and repositories. These add-ons make it that much easier to develop a Python script to do whatever you want.
Python is often used in the development of Remote Access Trojans, or RATs. This is because Python makes it very easy to implement libraries that can take screenshots, use a webcam, and even make web requests. It's also easy develop malicious code that can run on many different systems and devices, including Android devices.
One of the main drawbacks to using Python for malware is that its file sizes are larger than other common languages. Python must also be installed on the system for a Python script to run. This is fine for MacOS and Linux. Windows doesn't come with it installed, but it's pretty easy to convert Python scripts to Windows-compatible executables.
In addition to Python, attackers often use shells. A shell is a program that provides an interface that gives users access to operating system functions and services. We generally associate shells with command line interfaces, but they can have graphical interfaces too. These programs can provide access to core operating system functions, which makes them exploitation targets.
You can type commands directly into the shell window or run pre-written scripts. A script is simply a plain text file with the commands you want to run typed in, just like you would type them into the shell window. When the script runs, the commands are executed.
Now let's talk about PowerShell. PowerShell is a management framework that Microsoft developed to replace the Command Prompt and give users more power and control over the Windows system. PowerShell is built on the .NET frameworks and can run on multiple operating systems, including MacOS and Linux.
PowerShell uses cmdlets to carry out commands. Cmdlets are tiny scripts that are used to perform certain functions. Some cmdlets replace older commands and provide more advanced functions. Users can combine these cmdlets to develop scripts that automate tasks and configure just about anything in Windows.
Malicious PowerShell scripts pose a major security threat. For example, let's talk about fileless malware. PowerShell scripts can run in the memory of the system--they don't need an actual file executable to run. An attacker can take advantage of this function by sending a phishing email. When the victim clicks the link, a PowerShell script is loaded in the background that can download and run other malware programs. Because these attacks are fileless, anti-virus programs generally can't detect them.
Bash is a command shell and scripting language used in most Linux distros and MacOS versions prior to Catalina. Bash was released in 1989, and it's still heavily used. When you use a command in Linux, Bash works in the background to execute that command using environment variables.
Since many web servers run on Linux's Apache platform, Bash malware can be designed to attack these systems. A well-known malware called Shellshock uses Bash commands to exploit a flaw within the Bash shell itself, allowing an attacker to inject malicious commands.
Malware that exploits these shell programs essentially use the operating system against itself. This makes these scripts difficult to detect and prevent. Keeping anti-malware up to date and training users not to click unknown links or run unknown programs is vital.
All right. Next, we're going to talk about macros, which are similar to scripts. Macros are little bits of code that can be used to run a series of steps or functions in an application, making common tasks more efficient. Many different programs can make use of macros, but the most common use of macros is in the Microsoft Office programs.
Microsoft Office programs can use the Visual Basic for Applications, or VBA, programming language to create and run macros. VBA can be a powerful programming language and can even be used to run commands in Windows using the shell function or delete files from your hard drive using the Kill function.
An example of a devastating macro malware is the macro virus Melissa. In 1999, Melissa was distributed as a Word document, and when it was opened, a macro ran that pulled the first 50 users from the user's Outlook address book and mailed a copy of the infected Word document. Melissa spread extremely quickly and shut down more than 300 corporations and government agencies temporarily as their networks were overloaded. The total estimated damage of Melissa was around $80 million dollars.

In newer version of Microsoft Office, macros are disabled by default, and a user must specifically allow them to run. This helps to keep our systems safe from malicious code. But if someone uses macros often and has them enabled, their system is extremely vulnerable.
That'll wrap up this lesson. We've covered some methods for generating and distributing malicious code. First, we looked at the popular scripting language Python. Python is used to create all sorts of great programs and scripts, but because of its ease of use, many hackers use it to develop malicious code.
Then we covered command shells like PowerShell and Bash. These shells generally allow access to all sorts of critical operating system functions, meaning malicious code can cause them serious damage.
Finally, we looked at how macros can be exploited to run malicious code on a computer. Microsoft Office programs use the VBA programming language to develop macros to automate tasks, but it can be exploited to distribute malicious code.

6.5.11 Malicious Code Facts

Malicious software (malware) is perhaps the most dangerous threat to any computing device. Malware can be created using a variety of programming languages and methods.

This lesson covers the following topics:

- Malicious code indicators
- Python
- Command shells
- Macros

Malicious Code Indicators

Many network attacks are launched by compromised hosts running various types of malicious code. Indicators of malicious code execution are either caught by endpoint protection software or discovered after the fact in logs of how the malware interacted with the network, file system, and registry. To understand how and where these indicators are generated, it is helpful to consider the main types of malicious activity:

- Shellcode — this is a minimal program designed to exploit a vulnerability in the OS or a legitimate app to gain privileges or to drop a backdoor on the host if run as a Trojan. Having gained a foothold, this type of attack will be followed by some type of network connection to download additional tools.
- Credential dumping — the malware might try to access the credentials file (SAM on a local Windows workstation) or sniff credentials held in memory by the lsass.exe system process. Additionally, a DCSync attack attempts to trick a domain controller into replicating its user list along with its credentials with a rogue host.
- Pivoting/lateral movement/insider attack — the general procedure is to use the foothold to execute a process remotely, using a tool such as PsExec or PowerShell.The attacker might be seeking data assets or may try to widen access by changing the system security configuration, such as opening a firewall port or creating an account. If the attacker has compromised an account, these commands can blend in with ordinary network operations, though they could be anomalous behavior for that account.
- Persistence — this is a mechanism that allows the threat actor's backdoor to restart if the host reboots or the user logs off. Typical methods are to use AutoRun keys in the registry, add a scheduled task, or use Windows Management Instrumentation (WMI) event subscriptions.

Python

Python has become one of the most popular programming languages. First released in 1991, Python is designed to be easy to learn and read. It can be used on most operating systems, including Windows, MacOS, and Linux. Python can also take advantage of open-source Python packages and repositories.

Many Remote Access Trojans (RATs) are designed using Python. Python makes it easy to implement libraries that allow the RAT to perform functions such as:

- Taking screenshots.
- Enabling the webcam and viewing it remotely.
- Making web requests.
- Making phone calls.

Python also makes it very simple to develop malicious code that can be run on many different systems and devices, including Android devices.

One of the main drawbacks to using Python for malware is the file size. Python files are larger than other common languages. Also, Python must be installed on a system for a Python script to run. This works for MacOS and Linux, but Windows does not come with it installed. Python scripts can be converted to Windows-compatible executables fairly easily.

Command Shells

A shell provides an interface for users to access operating system functions and services. Shells are generally associated with command line interfaces, but they can have graphical interfaces also. Because these programs provide access to core operating system functions, they are extremely dangerous when exploited.

Commands can be typed directly into the shell program or can be run from a script. A script is a plain-text document that has the commands typed out just like they would be in the shell. When the script is run, the commands are executed.

Two of the more heavily used shells are PowerShell and Bash. The following table describes these two shell programs:

Shell Program	Description
PowerShell	PowerShell is a management framework that Microsoft developed to replace Command Prompt and give users more power and control over the Windows system. PowerShell is built on the .NET framework and can now be run on multiple operating systems, including MacOS and Linux. PowerShell uses cmdlets to execute commands. Cmdlets are tiny scripts that perform certain functions. Some cmdlets replace older commands and provide more advanced functions. Users can combine these cmdlets to develop scripts to automate tasks and configure just about anything in Windows. Malicious PowerShell scripts pose a major security threat. These scripts can run in the memory of the system, which means they do not need an executable to run. • An attacker can take advantage by running malicious PowerShell scripts in the background. • This type of malware is known as *fileless malware.* Fileless malware is especially dangerous because many anti-virus programs are unable to detect it.
Bash	Bash is a command shell and scripting language used in most Linux distributions and MacOS versions prior to Catalina.

	Bash was released in 1989 and is still heavily used. When a command is executed in Linux, Bash works in the background to execute the command using environment variables. Since many web servers run on Linux's Apache platform, malware can be designed in Bash to attack these systems. A well-known malware called Shellshock uses Bash commands to exploit a flaw within the Bash shell. The flaw allows an attacker to inject malicious commands.

Malware that exploits shell programs uses the operating system against itself, making this type of malware difficult to detect and prevent.

Keeping anti-malware up to date and training users not to click unknown links or run unknown programs is vital to staying safe.

Macros

Macros are similar to scripts in that they are little bits of code used to perform a series of steps or functions. Macros, however, are used inside specific applications. Many different programs can make use of macros, but the most common use of macros is in the Microsoft Office programs.

Microsoft Office programs use the Visual Basic for Applications (VBA) programming language to create and run macros. If the Office program is not configured properly, malicious VBA code can be used to open a shell on the Windows operating system. The shell can be used to perform malicious attacks.

In newer versions of Microsoft Office, macros are disabled by default, and a user must specifically allow them to run.

6.5.12 Practice Questions (Section Quiz)

q_analyz_netattacks_amplified_secp8

A threat actor has initiated an attack against a company's network. The threat actor is exploiting a weakness in a specific application protocol, manipulating the request in such a way that the target is forced to respond with a large amount of data, thereby consuming a significant amount of the target's bandwidth.

Which type of attack does this scenario represent?

Answers:

- Distributed denial-of-service (DDoS) attack
- Reflected attack
- ***Amplified attack**
- Direct attack

Explanation:

Amplified attack is the correct answer. An amplification attack targets weaknesses in specific application protocols to make the attack more effective at consuming target bandwidth. The threat actor manipulates the request in such a way that the target is forced to respond with a large amount of data, which is exactly what is described in the scenario.

Distributed denial-of-service (DDoS) attack is incorrect because while a DDoS attack involves multiple hosts launching an attack simultaneously, it does not specifically involve the exploitation of a weakness in a specific application protocol to force the target to respond with a large amount of data.

Reflected attack is incorrect because a reflected attack involves the threat actor spoofing the victim's IP address and using third-party servers to direct responses to the victim host. The scenario does not mention the use of third-party servers or IP address spoofing.

Direct attack is incorrect because a direct attack involves the threat actor directly attacking the victim's network without the use of third-party servers or specific application protocols. The scenario describes the exploitation of a specific application protocol, which is characteristic of an amplified attack.

q_analyz_netattacks_arp_pois_01_secp8

Which of the following is the term used to describe what happens when an attacker sends falsified messages to link their MAC address with the IP address of a legitimate computer or server on a network?

Answers:

- Port mirroring
- MAC flooding
- ***ARP poisoning**
- MAC spoofing

Explanation:

Address Resolution Protocol (ARP) poisoning is when an attacker sends fake ARP messages to link their MAC address with the IP address of a legitimate computer or server on the network. Once their MAC address is linked to an authentic IP address, the attacker can receive any messages directed to the legitimate address. As a result, the attacker can intercept, modify, or block communications to the legitimate MAC address.

Port mirroring creates a duplicate of all network traffic on a port and sends it to another device.

MAC flooding is when an attacker intentionally floods a content-addressable memory table with Ethernet frames, each originating from different MAC addresses. Once the table starts to overflow, the switch responds by broadcasting all incoming data to all ports, basically turning itself into a hub instead of a switch.

MAC spoofing is done to enable the bypass of access control lists on servers or routers by either hiding a computer on a network or by allowing it to impersonate another network device.

q_analyz_netattacks_arp_pois_02_secp8

Which of the following attacks tries to associate an incorrect MAC address with a known IP address?

Answers:

- ***ARP poisoning**
- Hijacking
- Null session
- MAC flooding

Explanation:

ARP spoofing/poisoning associates the attacker's MAC address with the IP address of a victim's device. When computers send an ARP request to get the MAC address of a known IP address, the attacker's system responds with its MAC address.

MAC flooding overloads the switch's MAC forwarding table to make the switch function like a hub. The attacker floods the switch with packets, each containing different source MAC addresses. The flood of packets fills up the forwarding table and consumes so much of the memory in the switch that it causes the switch to enter a state called Fail Open mode, in which all incoming packets are broadcast out of all ports (as with a hub), instead of just to the correct ports.

A null session is the ability to log on using a blank username and password. With hijacking, an attacker steals an open session, inserting themself into the session in place of the original client.

q_analyz_netattacks_client_cache_poisoning_secp8

A threat actor has successfully manipulated a client's DNS cache, causing the client to resolve domain names to incorrect IP addresses controlled by the threat actor. This allows the threat actor to redirect the client's network traffic to malicious websites.

Which type of attack does this scenario represent?

Answers:

- Man-in-the-middle attack
- On-path attack
- ***Client cache poisoning**
- Distributed denial-of-service (DDoS)

Explanation:

Client cache poisoning is the correct answer. Client cache poisoning involves a threat actor manipulating a client's DNS cache, causing the client to resolve domain names to incorrect IP addresses. This is exactly what is described in the scenario.

While a man-in-the-middle attack does involve intercepting and possibly altering communication between two parties, it typically involves the threat actor actively impersonating one or both parties to deceive the other. The scenario does not mention any impersonation, only manipulation of the client's DNS cache.

On-path attack is incorrect because it involves a threat actor positioning themselves in the communication path between two parties and intercepting and possibly altering the communication without their knowledge. The scenario does not describe any interception of communication, only manipulation of the client's DNS cache.

Distributed denial-of-service (DDoS) attack is incorrect because a DDoS attack involves overwhelming a network or service with traffic from multiple sources to cause a denial-of-service. The scenario does not describe any overwhelming of network resources or denial of service.

q_analyz_netattacks_ddos_secp8

A major online retail company has recently been experiencing intermittent downtime of its website. Network analysts observe a massive influx of traffic from multiple sources to the server. However, the traffic seems redirected from other systems.

What type of attack is the company likely experiencing?

Answers:

- ***Distributed denial-of-service (DDoS)**

- Collision
- Injection
- Buffer overflow

Explanation:

In this scenario, distributed denial-of-service (DDoS) attacks align with the influx of traffic from multiple sources, causing downtime.

Collision is mainly used in the context of cryptographic hash functions and does not relate to the influx of traffic causing downtime.

Injection attacks occur when an attacker sends harmful data to a system, tricking it into executing unintended commands. They typically do not result in a massive influx of traffic.

Buffer overflow can lead to crashes or exploitable conditions, but it is not a direct cause of a flood of internet traffic.

q_analyz_netattacks_dns_pois_01_secp8

Which type of denial-of-service (DoS) attack occurs when a name server receives malicious or misleading data that incorrectly maps host names and IP addresses?

Answers:

- ***DNS poisoning**
- ARP poisoning
- Spam
- SYN flood

Explanation:

DNS poisoning occurs when a name server receives malicious or misleading data that incorrectly maps host names and IP addresses. In a DNS poisoning attack:

- Incorrect DNS data is introduced into a primary DNS server.
- The incorrect mapping is made available to client applications through the resolver.
- Traffic is directed to incorrect sites.

ARP poisoning corrupts the ARP cache or sends incorrect ARP data that spoofs MAC addresses, causing devices to send frames to the wrong host or an unreachable host.

Spam sent in such great amounts can consume bandwidth or fill a mailbox, leaving no room for legitimate traffic.

A SYN flood exploits the TCP three-way handshake.

q_analyz_netattacks_dns_pois_02_secp8

While using the internet, you type the URL of one of your favorite sites in the browser. Instead of going to the correct site, the browser displays a completely different website. When you use the IP address of the web server, the correct site is displayed.

Which type of attack has likely occurred?

Answers:

- ***DNS poisoning**
- Hijacking
- Man-in-the-middle
- Spoofing

Explanation:

Because the correct site shows when you use the IP address, you know that the main website is still functional and that the problem is likely caused by an incorrect domain name mapping. DNS poisoning occurs when a name server receives malicious or misleading data that incorrectly maps host names and IP addresses. In a DNS poisoning attack:

- Incorrect DNS data is introduced into the cache of a primary DNS server.
- The incorrect mapping is made available to client applications through the resolver.

Spoofing is used to hide the true source of packets or redirect traffic to another location. Spoofing attacks use modified source and destination addresses in packets and can include site spoofing that tricks users into revealing information.

A man-in-the-middle attack is used to intercept information passing between two communication partners. TCP/IP hijacking is an extension of a man-in-the-middle attack in which the attacker steals an open and active communication session from a legitimate user.

With spoofing, man-in-the-middle, and hijacking, the attack would be successful regardless of whether the DNS name or the IP address was used.

q_analyz_netattacks_dns_pois_03_secp8

An attacker uses an exploit to push a modified hosts file to client systems. This hosts file redirects traffic from legitimate tax preparation sites to malicious sites to gather personal and financial information.

Which kind of exploit has been used in this scenario?

Answers:

- Reconnaissance
- ***DNS poisoning**
- Man-in-the-middle
- Domain name kiting

Explanation:

DNS poisoning (also known as DNS cache poisoning) occurs when a name server receives malicious or misleading data that incorrectly maps host names and IP addresses. In a DNS poisoning attack:

- Incorrect DNS data is introduced into the cache of a primary DNS server.
- The incorrect mapping is made available to client applications.

Reconnaissance is used to gather information for an attack. The goal is to obtain DNS records that identify computer names and IP addresses in a network.

Domain name kiting occurs when spammers exploit domain registration by taking advantage of the five-day grace period for a newly registered domain name to acquire domains and never pay for the registration of domain names. They accomplish this by unregistering a domain name just before the grace period is up and then immediately re-registering the domain name.

Man-in-the-middle attacks are used to intercept information passing between two communication partners.

q_analyz_netattacks_dns_pois_04_secp8

A company CEO is upset after receiving a call from a reporter at a local news station that the company is apparently at a launching point for a massive attack. The reporter provided detailed IP logs, and the network team reviewed them but could not find similar entries.

What could be a possible explanation for the different records?

Answers:

- ***DNS poisoning**
- DNS client cache poisoning
- DNS-based on-path attack
- DNS attack indicators

Explanation:

Domain Name System (DNS) poisoning is an attack in which network traffic appears to be coming from another location to confuse the company looking for an infection that does not exist.

DNS client cache poisoning occurs when an attacker accesses the local client's host file, placing a false name-to-IP address mapping in the file, effectively poisoning the DNS cache to redirect traffic.

Within a DNS-based on-path attack, if the threat actor has access to the same local network, the attacker can use Address Resolution Protocol (ARP) poisoning to respond to DNS queries from the victim with spoofed replies.

DNS attack indicators are bits of information from a DNS server to assist with security intelligence and attack indicators.

q_analyz_netattacks_lifecycle_01_secp8

A threat actor has successfully breached a company's network and has installed malicious code on a compromised host. The threat actor is now operating the compromised host remotely and maintaining access to it over a period of time. The threat actor's activity is disguised as part of the network's regular traffic.

Detection of this type of activity usually depends on identifying anomalous connection endpoints.

Which stage of the cyberattack lifecycle does this scenario represent?

Answers:

- Reconnaissance
- Weaponization, delivery, and breach
- ***Command and Control**
- Data exfiltration

Explanation:

Command and Control is the correct answer. In this stage, the threat actor operates a compromised host remotely and maintains access to it over a period of time. The threat actor has to disguise the incoming command and outgoing beaconing activity as part of the network's regular traffic, which is exactly what is described in the scenario.

Reconnaissance is incorrect because reconnaissance refers to the initial stage of the cyberattack lifecycle where the threat actor uses scanning tools to learn about the network. In the given scenario, the threat actor has already breached the network and is operating a compromised host remotely.

Weaponization, delivery, and breach are incorrect because this stage refers to techniques that allow a threat actor to get access without having to authenticate. This typically involves various types of malicious code being directed at a vulnerable application host or service over the network. In the given scenario, the threat actor has already gained access and is now maintaining it.

Data exfiltration is incorrect because data exfiltration refers to obtaining an information asset and copying it to the attacker's remote machine. In the given scenario, there is no mention of the threat actor obtaining or copying any information.

q_analyz_netattacks_lifecycle_02_secp8.

A threat actor is attempting to learn passwords or cryptographic secrets that will allow them to obtain authenticated access to network systems.

They are using various techniques to gather this information without yet having breached the network.

Which stage of the cyberattack lifecycle does this scenario represent?

Answers:

- Reconnaissance
- ***Credential harvesting**
- Command and Control
- Data exfiltration

Explanation:

Credential harvesting is the correct answer. In this stage, the threat actor attempts to learn passwords or cryptographic secrets that will allow them to obtain authenticated access to network systems. This is exactly what is described in the scenario.

Reconnaissance is incorrect because reconnaissance refers to the initial stage of the cyberattack lifecycle where the threat actor uses scanning tools to learn about the network. While this stage may involve some gathering of information, it does not specifically involve the collection of passwords or cryptographic secrets.

Command and Control is incorrect because in this stage, the threat actor operates a compromised host remotely and maintains access to it over a period of time. The scenario does not describe the threat actor having breached the network or operating any hosts remotely.

Data exfiltration is incorrect because data exfiltration refers to obtaining an information asset and copying it to the attacker's remote machine. In the given scenario, there is no mention of the threat actor obtaining or copying any information.

q_analyz_netattacks_on-path_01_secp8

A network administrator suspects an attacker is intercepting and potentially modifying communications between their organization's server and the client systems. The attacker is not detected by either party during this process.

Which type of attack is the network administrator likely observing in this instance?

Answers:

- ***On-path attack**
- Domain Name System (DNS) attack
- Replay attack
- Distributed denial-of-service (DDoS) attack

Explanation:

An on-path attack involves an attacker intercepting and potentially modifying communications between two parties who believe they're communicating directly with each other.

A DNS attack involves the manipulation of DNS entries to redirect traffic to malicious sites. While it is a severe threat, it does not include the direct interception or modification of ongoing communications.

A replay attack involves the interception and retransmission of a valid data transmission. It does not include the real-time interception and modification of communications between two parties.

A distributed denial-of-service (DDoS) attack floods a target with traffic from multiple sources, causing service disruption. It does not intercept or alter communications between a server and client systems.

q_analyz_netattacks_on-path_02_secp8

A threat actor has positioned themselves in the communication path between two parties in a network. The threat actor is intercepting and possibly altering the communication between the two parties without their knowledge.

Which type of attack does this scenario represent?

Answers:

- Man-in-the-middle attack
- ***On-path attack**
- Distributed denial-of-service (DDoS) attack
- Direct attack

Explanation:

On-path attack is the correct answer. An on-path attack involves a threat actor positioning themselves in the communication path between two parties and intercepting and possibly altering the communication without their knowledge. This is exactly what is described in the scenario.

While a man-in-the-middle attack does involve intercepting and possibly altering communication between two parties, it typically involves the threat actor actively impersonating one or both parties to deceive the other. The scenario does not mention any impersonation, only interception and possible alteration of communication.

Distributed denial-of-service (DDoS) Attack is incorrect because a DDoS attack involves overwhelming a network or service with traffic from multiple sources to cause a denial of service. The scenario does not describe any overwhelming network resources or denial of service.

Direct attack is incorrect because a direct attack involves the threat actor directly attacking the victim's network without the use of third-party servers or specific application protocols. The scenario describes the

q_analyz_netattacks_reflected_secp8

A threat actor has launched an attack against a company's network. The threat actor spoofs the victim's IP address and attempts to open connections with multiple third-party servers. Those servers direct their responses to the victim host, rapidly consuming the victim's available bandwidth.

Which type of attack does this scenario represent?

Answers:

- Distributed denial-of-service (DDoS) attack
- ***Reflected attack**
- Amplified attack
- Direct attack

Explanation:

Reflected attack is the correct answer. In a reflected attack, the threat actor spoofs the victim's IP address and attempts to open connections with multiple third-party servers. Those servers direct their responses to the victim host, which can rapidly consume the victim's available bandwidth.

Distributed denial-of-service (DDoS) attack is incorrect because while a DDoS attack involves multiple hosts launching an attack simultaneously, it does not specifically involve the spoofing of the victim's IP address and the use of third-party servers to direct responses to the victim host.

Amplified attack is incorrect because an amplification attack is a type of reflected attack that targets weaknesses in specific application protocols to make the attack more effective at consuming target bandwidth. The scenario does not mention any specific application protocols being targeted.

Direct attack is incorrect because a direct attack involves the threat actor directly attacking the victim's network without the use of third-party servers. The scenario describes the use of third-party servers to direct responses to the victim host, which is characteristic of a reflected attack.

q_analyz_netattacks_spoof_secp8

A router on the border of your network detects a packet with a source address that is from an internal client, but the packet was received on the internet-facing interface.

This is an example of which form of attack?

Answers:

- Snooping
- Sniffing
- ***Spoofing**
- Spamming

Explanation:

This is an example of spoofing. Spoofing is the act of changing or falsifying information in order to mislead or re-direct traffic. In this scenario, a packet received on the inbound interface cannot receive a valid packet with a stated source that is from the internal network.

Snooping is the act of spying on private information or communications. One type of snooping is sniffing.

Sniffing is the act of capturing network packets in order to examine the contents of communications.

Spamming is sending a victim unwanted and unrequested email messages.

poison_arp_01

What is the MAC address of the first responding device?

Answers:

- 00:00:1B:11:22:33
- 00:00:1b:11:22:33
- 00:00:1b_11:22:33
- 00:00:1B:11:22:33
- 00:00:1B_11:22:33

poison_arp_02

What is the MAC address of the duplicate responding device?

Answers:

- 00:00:1B:33:22:11
- 00:00:1B:33:22:11
- 00:00:1b:33:22:11
- 00:00:1b_33:22:11
- 00:00:1B_33:22:11

q_l_ddos_eh1_01

What indicates that this is a distributed denial-of-service (DDoS) attack?

Answers:

- There are multiple source addresses for the SYN packets with the destination address 128.28.1.1.
- The hex value of the SYN flag is 0x002.
- ***There is a flood of SYN packets without matching SYN-ACK packets.**
- The destination address for all SYN packets is 128.28.1.1.

q_mal_code_bash_sec8

Which of the following statements about Bash is true?

Answers:

- Bash is a command shell and scripting language used only in Windows operating systems.
- Bash was released in 2000 and is rarely used today.
- ***Bash works in the background to execute commands using environment variables.**
- Bash cannot be used to design malware that attacks systems running on Linux's Apache platform.

Explanation:

Bash does work in the background to execute commands using environment variables.

Bash is not used in Windows operating systems. It is used in most Linux distributions and MacOS versions prior to Catalina.

Bash was released in 1989, not 2000, and is still heavily used today.

Malware can actually be designed in Bash to attack systems running on Linux's Apache platform.

q_mal_code_credential_dumping_sec8

You are a cybersecurity analyst at a tech company. You have noticed some unusual activity on a host within your network. You suspect that the host may be compromised and running malicious code.

Which of the following indicators would MOST likely suggest that the host is compromised?

Answers:

- The host is showing signs of shellcode execution.
- The host is showing signs of pivoting/lateral movement.
- ***The host is showing signs of credential dumping.**
- The host is showing signs of persistence mechanisms.

Explanation:

Credential dumping is the correct answer and is a clear sign of a compromised host. Malware often tries to access the credentials file or sniff credentials held in memory by the system process. This is a strong indicator of malicious activity and is more definitive than the other options.

Shellcode execution is a minimal program designed to exploit a vulnerability in the OS or a legitimate app to gain privileges or to drop a backdoor on the host if run as a Trojan. While this could be a sign of a compromised host, it is not as definitive as credential dumping.

Pivoting/lateral movement refers to the procedure used by an attacker to move around within a network, often seeking data assets or trying to widen access by changing the system security configuration. While this could indicate a compromised host, it is not as definitive as credential dumping.

Persistence mechanisms allow the threat actor's backdoor to restart if the host reboots or the user logs off. While this could indicate a compromised host, it is not as definitive as credential dumping.

q_mal_code_powershell_01_sec8

As a system administrator, you notice unusual network activity on a company server. Upon investigation, you discover that a PowerShell script is running in the background.

What type of malware is MOST likely responsible for this activity?

Answers:

- ***Fileless malware**
- Macro virus
- Worm
- Trojan horse

Explanation:

Fileless malware is the correct answer. Fileless malware operates in the memory of the system and does not require a file to run. It is known for using legitimate tools like PowerShell to execute malicious activities. In this scenario, the PowerShell script running in the background is a typical characteristic of fileless malware.

A macro virus is a type of malware embedded in a document and executed when the document is opened. It does not typically use PowerShell for its operations, making this an incorrect answer.

A worm is a type of malware that can replicate itself and spread to other systems, often exploiting system vulnerabilities. While a worm could potentially use PowerShell, the scenario does not provide evidence of replication or spreading, making this an unlikely answer.

A Trojan horse is a type of malware that disguises itself as a normal file or program to trick users into downloading and installing it. While a trojan could potentially use PowerShell, the scenario does not provide evidence of a disguised file or program, making this an unlikely answer.

q_mal_code_powershell_02_sec8

Which of the following statements about PowerShell is true?

Answers:

- PowerShell is a management framework developed by Apple to replace Terminal.
- PowerShell is built on the Java framework and can only be run on Linux operating systems.
- ***PowerShell uses cmdlets to execute commands.**
- PowerShell scripts cannot run in the memory of the system and always need an executable to run.

Explanation:

PowerShell uses cmdlets, which are small scripts that perform certain functions, to execute commands.

PowerShell is a management framework developed by Microsoft, not Apple, and it was designed to replace Command Prompt, not Terminal.

PowerShell is built on the .NET framework, not the Java framework, and it can be run on multiple operating systems, including Windows, MacOS, and Linux.

PowerShell scripts can run in the memory of the system, which means they don't always need an executable to run. This type of malware is known as fileless malware.

q_mal_code_python_sec8

Why is Python a popular programming language for creating Remote Access Trojans (RATs)?

Answers:

- Python is only compatible with Windows operating systems.
- Python's syntax is difficult to learn and understand.
- ***Python can implement libraries that allow RATs to perform various functions.**
- Python scripts are small in size and do not require Python to be installed on the system to run.

Explanation:

Python's ability to implement libraries allows RATs to perform a variety of functions, such as taking screenshots, enabling the webcam and viewing it remotely, making web requests, and making phone calls, makes it a popular programming language for creating RATs.

Python is a versatile language that can be used on most operating systems, including Windows, MacOS, and Linux, not just Windows.

Python is known for its easy-to-learn and readable syntax, which makes it a popular choice for many types of programming, including creating RATs.

One of the main drawbacks to using Python for malware is the file size. Python files are larger than other common languages. Also, Python must be installed on a system for a Python script to run.

q_mal_code_vba_sec8

How can Visual Basic for Applications (VBA) be used to perform malicious attacks?

Answers:

- ***VBA can be used to create a macro virus that opens a shell on the Windows operating system.**
- VBA can be used to disable all security features on a computer system.
- VBA can be used to physically damage the hardware components of a computer.
- VBA can be used to delete all files on a computer system automatically.

Explanation:

VBA can be used to create a macro virus that opens a shell on the Windows operating system. This shell can then be used to perform malicious attacks.

While VBA can be used to perform malicious activities, it cannot directly disable all security features on a computer system.

VBA is a programming language and cannot physically damage the hardware components of a computer.

While a malicious VBA script could potentially delete files, it is not accurate to say that VBA can be used to delete all files on a computer system automatically.

6.6 Analyzing Password Attacks

As you study this section, answer the following questions:

- Where would an attacker gather information to guess a user's password?
- What social engineering technique involves looking through trash?

- What does password spraying help the attacker avoid?
- What is the best defense against password-cracking attempts?
- What is the difference between an online and an offline password attack?

In this section, you will learn to:

- Crack a password using rainbow tables
- Crack a password with John the Ripper

The key terms for this section include:

Term	Definition
Online password attack	An attack where the threat actor interacts with the authentication service directly—a web login form or VPN gateway, for instance.
Offline attack	An attack where once the attacker has obtained a password database, the cracker does not interact with the authentication system.
Social engineering	An activity where the goal is to use deception and trickery to convince unsuspecting users to provide sensitive data or to violate security guidelines.
Shoulder surfing	An eavesdropping technique where the listener obtains passwords or other confidential information by looking over the shoulder of the target.
Brute force attack	A type of password attack where an attacker uses an application to exhaustively try every possible alphanumeric combination to crack encrypted passwords.
Password spraying	A brute force attack in which multiple user accounts are tested with a dictionary of common passwords.
Dictionary attack	A type of password attack that compares encrypted passwords against a predetermined list of possible password values.
Rainbow attack	Similar to dictionary attacks, however, a rainbow attack uses special tables called rainbow tables that have common passwords and the generated hash of each password.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.4 Explain the importance of using appropriate cryptographic solutions. • Hashing

	• Salting 2.2 Explain common threat vectors and attack surfaces. • Default credentials • Human vectors/social engineering 2.4 Given a scenario, analyze potential indicators of malicious activity. Password attacks • Spraying • Dictionary • Brute force 5.6 Given a scenario, implement security awareness practices. • User guidance and training ○ Password management
TestOut Security Pro	5.2 Assessment Techniques Analyze password attacks

6.6.1 Password Attacks (Lesson Video)

Transcript:

Passwords are oftentimes the main defense against unauthorized access to a computer system or sensitive data, and attackers have a variety of methods they can use to crack users' passwords. Some of the more common methods are social engineering, brute force attacks, and rainbow attacks. In this lesson, I'll go over how these attacks work and how you can defend against them.

Social engineering is the art of manipulating the weakest link in network security, which is the human element. A skilled attacker can use social engineering to learn a user's password through password guessing, user manipulation, or shoulder surfing.
Guessing a user's password can be difficult, but there are techniques that an attacker can use to make this simpler. The first thing an attacker might do is try default logins and common passwords like password123. An attacker might also use social media to gather personal information such as pet names, family, first car, birthday, and more. Then the attacker uses this information to answer security questions and reset the password itself.
An attacker might also try to interact with a user to trick them into revealing their password. For example, they might call the user pretending to be a technician with an urgent problem for which they need the user's password to resolve. Attackers continue to use this method because, surprisingly, it's still very easy.
An attacker might also use social engineering to gain physical access to an office building. Once inside, they look around for login information that users have written down. Unfortunately, many users write their login information on a sticky pad and put it on their monitor or under their mouse pad. This makes it fairly easy for an attacker to find.
Attackers also go dumpster diving to find these notes that might've been inadvertently thrown away. These people aren't above searching through your trash to gain access to your personal information.
Shoulder surfing is a passive technique where the attacker simply watches a user's keystrokes as they type in their password. This requires access to the user, but it can be accomplished with social engineering.

Your best defense against these kinds of password attacks is education. You must be trained on how to handle these situations. You should know emphatically that no one will ever need to ask for your passwords, and that you should never carelessly write your login information down. With proper user training, attackers have to resort to more technical means to crack passwords.
A brute force password attack can be a very time-consuming proposition. The attacker attempts to guess passwords by using a cracking tool that submits every possible letter, number, and symbol combination in a short amount of time. These attacks can be carried out online or offline.
An online brute force attack requires the attacker to submit passwords with the same user interface while the target is up and running. If the attacker targets a website, they keep submitting logins to the site interface. If the attacker targets a computer, they submit the logins to the login screen.
The best defense against online brute force attacks is to implement lockout policies. This means that if someone enters an incorrect password multiple times in a short period, the system locks them out for a certain amount of time.
An offline brute force attack requires the attacker to somehow steal the password file and then run their attacks on it. This potentially gives the attacker unlimited attempts to run their attack, but it's much more difficult to pull off because they have to first get that password file.
Password spraying is another type of brute force attack that someone can use to get around lockout policies. Instead of attacking one account, the attacker submits a password to multiple user accounts. If none of those work, the attacker submits a different password to multiple accounts. Because there's a delay between submitting passwords on each account, the lockout policy is essentially circumvented.
A dictionary attack is yet another type of brute force attack. In this attack, the hacker compiles a huge list of words and phrases that can be used to guess the password. Weak and common passwords, such as password123, are extremely vulnerable to dictionary attacks.
Brute force attacks require a lot of time and computing power to be effective. This is why hackers use programs like John the Ripper, hashcat, Medusa, and Cain & Abel to facilitate the process.
Implementing proper password protocols is your best defense in these scenarios. A strong password should be at least 8 characters, but more is always better. It should also contain upper and lowercase letters, numbers, and symbols. It shouldn't contain common words and phrases. The longer and more complex your password is, the more time and effort it takes to brute-force it. Also, strongly consider using passphrases instead of passwords.
When you store a plaintext password, it's encrypted and generates a hash. Rainbow attacks are similar to dictionary attacks, but instead of trying to match up words and phrases, a rainbow attack uses tables that are already filled with word lists and their hashes. Rainbow attacks require less computing power and are much faster than brute force and dictionary attacks.
A rainbow table is a table of passwords and generated hashes. The hacker uses this table to match the password's hash instead of the password itself.
For example, let's say that a user's password is TestOut, and this is the generated hash. In the hacker's rainbow table, the password SecurityPro generates the same hash value. This is a hash collision, and the hacker could gain access to the system by sending the hash value without having the actual password itself.
The biggest drawback to rainbow tables is their size. Since different systems use different hashing algorithms, a table needs to be created for each target system. The necessary character sets also greatly increase the tables' sizes. A single table can range from 30 gigabytes to over 300.
The best way to defend against rainbow attacks is to salt your hashes. Salting the hash just means that some random characters are added at the beginning or end of the password, which ends up generating a completely different hash. The login server knows which part of the hash is salted, but anyone who intercepts the hash has no idea.
People use programs like rtgen, winrtgen, and RainbowCrack to create rainbow tables and tools like ophcrack to crack passwords using these tables.
That'll wrap up this lesson. In this lesson, we looked at different password attacks you might encounter. We first looked at social engineering methods, which target the users themselves. Then we covered brute force and dictionary attacks. These methods are essentially attempts at guessing passwords. Remember that these methods take quite a long time and usually require sophisticated computing power and knowledge to pull off. Finally, we looked at rainbow attacks. These attacks attempt to match password hashes instead of having to guess the actual password.

6.6.2 Password Attack Facts

This lesson covers the following topics:

- Password attacks

- Social engineering
- Brute force attacks
- Rainbow attacks
- Cracking passwords using rainbow tables

Password Attacks

Passwords are often the main defense against unauthorized access to computer systems and sensitive data. This makes passwords a prime target for attackers. A variety of attack methods have been developed to retrieve passwords. When a user chooses a password, the plaintext value is converted to a cryptographic hash. This means that, in theory, no one except the user (not even the systems administrator) knows the password because the plaintext should not be recoverable from the hash. A password attack aims to exploit the weaknesses inherent in password selection and management to recover the plaintext and use it to compromise an account.

Online Attacks

An online password attack is where the threat actor interacts with the authentication service directly—a web login form or VPN gateway, for instance. An online password attack can show up in audit logs as repeatedly failed logins and then a successful login or as successful login attempts at unusual times or locations. Apart from ensuring the use of strong passwords by users, online password attacks can be mitigated by restricting the number or rate of login attempts and shunning login attempts from known bad IP addresses.

Note that restricting logins can be turned into a vulnerability as it exposes the account to denial of service attacks. The attacker keeps trying to authenticate, locking out valid users.

Offline Attacks

An offline attack means that the attacker has managed to obtain a database of password hashes, such as %SystemRoot%\System32\config\SAM , %SystemRoot%\NTDS\NTDS.DIT (the Active Directory credential store) or /etc/shadow . Once the password database has been obtained, the cracker does not interact with the authentication system. The only indicator of this type of attack (other than misuse of the account in the event of a successful attack) is a file system audit log that records the malicious account accessing one of these files. Threat actors can also read credentials from host memory, in which case the only reliable indicator might be the presence of attack tools on a host.

If the attacker cannot obtain a database of passwords, a packet sniffer might be used to obtain the client response to a server challenge in an authentication protocol. Some protocols send the hash directly; others use the hash to derive an encryption key. Weaknesses in protocols using derived keys can allow for the extraction of the hash for cracking.

Social Engineering

Social engineering is the art of manipulation. In most networks, the weakest link is the human element. Hackers can take advantage of this to gain access to sensitive information, including passwords.

The following table explains some social engineering techniques to be aware of and protect against.

Social Engineering Technique	Description

Password guessing	Password guessing is usually not a very efficient method to crack a password. An attacker may first attempt to use default login information, such as admin/admin, or simple passwords like password123.
	
	If these do not work, the attacker can use publicly available information, such as on a target's social media, to make the process easier. Information such as the following can be used to guess a password or answer security questions and reset a user's password:
	
	• Birthday
	• First car
	• Family information
	  ○ Spouse's name
	  ○ Child's name
	  ○ Important dates
	• Important locations

User manipulation	A common social engineering technique is user manipulation. This involves the attacker interacting with the user to trick the user into revealing the username and password. For example, the attacker may call the target pretending to be from tech support with an urgent problem. The attacker asks for the target's login information to remote in to resolve the issue. User manipulation is a very successful technique and is still used quite often. User training is the best prevention method.
Physical access	An attacker can use social engineering to gain physical access to an office building. Once inside, the attacker can look around for login information that users have written down. Many users have a tendency to write login information on sticky notes and stick the notes on the monitor or place them under the mouse pad.
Dumpster diving	An attacker may dumpster dive (go through the trash) to find important documents or information that has been thrown out. Many users will throw out papers without realizing the importance of the information. Documents should always be shredded to prevent data loss due to dumpster diving.
Shoulder surfing	Shoulder surfing is an eavesdropping technique in which the attacker obtains passwords or other confidential information by looking over the shoulder of a user typing a password.

User education is the best defense against any form of social engineering. Users should be trained so that no one will ever ask for their login information and always be aware of their surroundings.

Brute Force Attacks

In a brute force attack, the attacker attempts to guess the password by using a cracking tool that submits every possible letter, number, and symbol combination in a short amount of time. A brute force password attack can be a very time-consuming attack.

The following table describes some of the brute force attack methods.

Brute Force Attack Method	Description
Online attack	An online brute force attack requires the attacker to submit the passwords using the same user login interface while the target is up and running. For example: • An attacker targeting a website will submit login attempts to the site interface. • An attacker targeting a computer will submit login attempts to the login screen. The best defense against this method is to implement lock-out policies. This means if the incorrect password is entered multiple times in a short period of time, the account will be locked for a specified amount of time.
Offline attack	Offline attacks require the attacker to somehow steal the password file. The attacker can then run attacks against that file with no limitations, such as lock-out policies. This is the ideal method for the attacker but is more difficult because it requires the attacker to steal the password file somehow.
Password spraying	Password spraying is another method that allows the attacker to avoid lockout policies. • Instead of attempting multiple logins using a single user account and different passwords, the attacker will use the same password with multiple user accounts. • The attacker will continue cycling through the user accounts, submitting passwords until a match is found. • Because there is a delay between submitting a password on each account, the lock-out policy can be avoided.
Dictionary attack	In a dictionary attack, the hacker uses a list of words and phrases to try to guess the password. • Dictionary attacks work well if weak passwords are used. • Using longer and uncommon passphrases is the best way to secure data against these attacks.

Some common password-cracking tools that can be used to carry out brute-force attacks are:

- John the Ripper
- Hashcat
- Medusa
- Cain and Abel

Implementing proper password protocols is the best defense against password-cracking attempts. A strong password should:

- Be at least eight characters; more is better.
- Contain upper and lower case letters.
- Contain numbers.

- Contain symbols.
- Not use common words or phrases.

A passphrase is the best option to use instead of a password.

Rainbow Attacks

When a plaintext password is stored, it is encrypted, and a hash is generated.

Rainbow attacks are similar to dictionary attacks, but instead of trying to match the words and phrases, a rainbow attack uses special tables called *rainbow tables* that are already filled with common passwords and their generated hashes. The attacker uses this table to match the hashes instead of the password. Rainbow attacks require less computing power and are much faster than brute-force attacks.

Storing rainbow tables requires a lot of storage. A single rainbow table can range anywhere from 30 GB to over 300 GB. The character set (lower and/or upper case letters, numbers, symbols) will greatly increase the size. A different rainbow table needs to be generated for each encryption algorithm.

The best defense against rainbow attacks is *salting* the hashes. Salting the hash means that random characters are added at the beginning or end of the password. This generates a completely different hash. The login server is programmed to identify the part of the hash that is salted, but anyone intercepting the hash will have no idea, so the hash cannot be decrypted.

Cracking Passwords Using Rainbow Tables

An encrypted plaintext password stored in a hash file can be cracked using rainbow tables. There are several types of programs that can be used to create and crack these types of passwords, such as:

- Rtgen
- Winrtgen
- RainbowCrack
- Ophcrack

As an example, the following table lists a few examples of the commands needed to create and sort a rainbow crack table:

Command	Description
rtgen	This command generates a rainbow table based on the parameters specified by the user. The parameters are: rtgen ***hash_algorithm charset plaintext_len_min plaintext_len_max table_index chain_len chain_num part_index*** Example: **rtgen md5 ascii-32-95 1 7 0 1000 1000 0** • *hash_algorithm* - A hashing algorithm is a mathematical algorithm that can convert an input data array of a certain type and arbitrary length to an output bit string of a fixed length. A rainbow table must be generated for the type of hash algorithm used. Although there are many hash algorithms that can be used, some of the more common are ntlm, md5, and sha1. • *charset* - A charset specifies all the possible characters for the plaintext. Some of the possible charset that can be used include:

	○ Numeric = [0123456789] ○ alpha = [ABCDEFGHIJKLMNOPQRSTUVWXYZ] ○ alpha-numeric = [ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789] ○ loweralpha = [abcdefghijklmnopqrstuvwxyz] ○ loweralpha-numeric = [abcdefghijklmnopqrstuvwxyz0123456789] ○ ascii-32-95 = ascii-32-95 = [!"#$%&'()*+,-./0123456789:;<=>?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_'abcdefghijklmngpqrstuvwxyz{|}~] • *plaintext_len_min* and *plaintext_len_max* - These two values, such as 1 7, specify the length of the plaintext. The next four parameters are advanced values and are beyond the scope of this lesson. Therefore, only a brief explanation is given here: • *table_index* - Specifies the reduction function. Examples are: 0, 1, 2, 3, 4. Zero is often used as the default. • *chain_len* - This specifies the rainbow chain length. • *chain_num* - This specifies the number of rainbow chains to generate. • *part_index* - The number of files used to store the rainbow table. If a value greater than zero is used, the rainbow table is saved in the number of smaller files specified by the value. As shown in the example above, common values for these four parameters are: **0 1000 1000 0**
rtsort	A rainbow table is an array of rainbow chains. Each rainbow chain has a starting point and an endpoint. The rtsort program sorts the rainbow chains by endpoint to make binary search possible. To sort a rainbow table, use the following command (the period at the end is part of the command): **rtsort .**

After the rainbow table has been created, you are now ready to crack the passwords. This can be done using the **rcrack** command.

The **rcrack** syntax is: **rcrack *path parameter***

The following table lists a few examples of how the **rcrack** command can be used:

Command	Description
rcrack . -l /root/hashes.txt	The **-l** parameter loads the hashes from a file, and each hash is shown on its own line. The hash is shown, followed by the cracked password. Example output: plaintext of 590cb9bZaC590/5b9b4b0/152d2321117 P@ssw0rd plaintext of 400238780e6c41f8f790161e6ed4aafc21 Test_Out@11_Last plaintext of 89BF04763BF91C9EE2DDBE23D735C73OBDD41FF2 NeverLAnd5

rcrack . -h ***hash_value***	The **-h** parameter loads and displays the results for a single hash. Example command: **rcrack . -h 590cb9bZaC590/5b9b4b0/152d2321117** Example output: **590cb9bZaC590/5b9b4b0/152d232111a P@ssw0rd hex:444387**

6.6.3 Using Rainbow Tables (Demo Video)

Transcript:

Nearly every computer system that requires password authentication must contain a password database. Because the information in databases is vulnerable to theft, storing passwords in plain text isn't a very good idea. Therefore, passwords are usually stored with a cryptographic hash.

When they want to crack a password, hackers often use rainbow tables to speed up the process. So, what is a rainbow table, exactly? A rainbow table is basically a table of passwords and the computed matching hashes. The advantage of using rainbow tables is that they save computation time compared to typical brute forcing. The disadvantage is that rainbow tables can take up a lot of storage space. Here, we can look at the website called RainbowCrack, and you can see that some of these are quite large, over half a terabyte in size.
In this demo, we're going to generate our own rainbow table using the RainbowCrack collection. We're going to use Kail Linux and RainbowCrack, which comes pre-installed.
To open the program, we just type 'rtgen', and it starts. Down here, we have a couple of examples. In the example, the first part is the hashing algorithm. Here, they have MD5. Next, we need to specify the character set. They've specified loweralpha numeric, which is the letters A to Z and numbers 0 to 9. 1 and 7 are the length of the passwords, so they're going to be between one and seven characters long. The rest of this information is some advanced configuration settings that aren't in the scope of what we're covering in this demo. You can find more information about the advanced features on the RainbowCrack website.
I'm going to go ahead and create our table. I'll do that by typing 'rtgen md5' numeric for our character set and 1 through 9 for our password length along with the rest of the parameters. Let's press Enter. When I do that, my rainbow table is created. Now, if I want to see where this was located, I can type in 'cd /usr/share/rainbowcrack' and press Enter. From here, I'll type in 'ls', and you can see my rainbow table file.
I'll clear the screen.
Now we have to sort our rainbow table. To do that, I'll type in 'rtsort .' and press Enter. Each rainbow chain has a start point and an end point. The rtsort program sorts the rainbow chains by end point to make binary searches possible. It's very important that you don't interrupt the sorting process.
All right. That's done, and now we're ready to crack a hash with our new table. I'll clear the screen again.
To crack a hash, I'll type in './rcrack .-h'. The dot is to specify our rainbow tables, and the -h is for hash. Now, we need to put in our hash. To do this, I'm going to go to this website, md5 hash generator. I can generate a hash by entering '123' and clicking Generate. I'll copy this hash, minimize this window, go back to my terminal, paste, and press Enter.
My results pop up very quickly. Here, I've found one of one plaintext. It only took a fraction of a second to run. And down here, I have the hash that I typed in. You can see the numbers I used, 123. So, we successfully cracked this hash with our rainbow table.
That's it for this demo. In this demo, we used the command line version of RainbowCrack to create a rainbow table. Then we sorted the table and used an online hash generator to create a hash that we were able to crack with the rainbow table we created.

6.6.4 Crack Password with Rainbow Tables (Simulation)

Scenario

A recent breach of a popular third-party service has exposed a password database. The security team is evaluating the risk of the exposed passwords for the company. The password hashes are saved in the root user's home directory,

/root/captured_hashes.txt . You want to attempt to hack these passwords using a rainbow table. The password requirements for your company are as follows:

- The password must be 12 or more characters in length.
- The password must include at least one uppercase and one lowercase letter.
- The password must have at least one of these special characters: !, ", #, $, %, &, _, ', *, or @.
- All passwords are encrypted using a hash algorithm of either md5 or sha1.

In this lab, your task is to:

- Create md5 and sha1 rainbow tables using **rtgen** .
- Sort the rainbow tables using the **rtsort** command.
- Crack the hashes using the **rcrack** command. You can run **rcrack** on an individual hash or the hash file (/root/captured_hashes.txt).
- Answer the questions.

The type of charset that can be used to create a rainbow table is stored in the **/usr/share/rainbowcrack/charset.txt** file. This file can be viewed using the **cat** command.

Explanation

Complete this lab as follows:

1. Create and sort an md5 and sha1 rainbow crack table.
    a. From the Favorites bar, select **Terminal** .
    b. At the prompt, type **rtgen md5 ascii-32-95 1 20 0 1000 1000 0** and press **Enter** to create an md5 rainbow crack table.
    c. Type **rtgen sha1 ascii-32-95 1 20 0 1000 1000 0** and press **Enter** to create a sha1 rainbow crack table.
    d. Type **rtsort .** and press **Enter** to sort the rainbow table.
2. Crack the password hashes using **-l** or **-h** .
    a. To crack the password contained in a hash file, type **rcrack . -l /root/captured_hashes.txt** and press **Enter** .
    This command lists the hashes continued in the hash file and shows the passwords.
    b. To crack the password contained in a hash, type **rcrack . -h *hash_value*** and press **Enter** .
    This command only shows the password for the specified hash.
    c. Repeat step 2b for the remaining hashes.
3. Answer the questions.
    a. From the top right, select **Answer Questions** .
    b. Answer the questions.
    c. Select **Score Lab** .

6.6.5 Crack Passwords (Demo Video)

Transcript:

All penetration testers and ethical hackers need the ability to crack passwords. In this demo, we're going to cover some ways to crack passwords in Linux and Windows.

One of the most popular password cracking programs is John the Ripper. It combines a number of password crackers into one package, autodetects password hash types, and includes a customizable cracker. You can run it against many

encrypted password formats, including several password hash types commonly found in Linux and Windows. You can also run John the Ripper against access passwords for compressed ZIP files and documents.
John the Ripper is a command line tool. There's also a GUI-based version called Johnny, which uses the underlying features of the command line version. Both are included with Kali Linux. We're going to use the command line version.
First, we need to open up a terminal. Now I want to point out the password file. When we do a dictionary attack, our cracking program needs a wordlist (a list of potential passwords) to refer to. So we need to switch to the folder where that password list is stored. By default, on Kali Linux, the wordlist is located in the /usr/share/john folder. To get there, I need to switch to that directory by typing 'cd /usr/share/john' and press Enter. Now, if I type 'ls', I'll be able to see the contents of this folder. I'm looking for this file, the password.lst file.
Now we're going to go back to the root directory. I can do that by just typing in 'cd'. I like to keep my terminal screen cleared off, so I'll 'clear' the screen.
Next, if I type in 'john', I get a list list some of the different options that I can use with John the Ripper. If you need to know something about a command's syntax, this page might help you out.
We're ready to crack our password. You might think that passwords would be stored in a folder called Passwords, but they're not. Linux passwords are kept in the /etc/shadow file. So, to crack the passwords on this system, I just need to type in 'john /etc/shadow' and press Enter. And that only took a few seconds to crack. It says it loaded two different passwords from two different salts. (If you remember, if a hash is salted, that means that there's extra data added to the hashes because there are two identical passwords being used here. Hashes are salted to make passwords unique in the system.)
Down here, we can see that it found the password for the root user.
Depending on your system, this process could take a lot longer. My password just happens to be toward the top of the list in my password.lst file.
Now we're going to jump over to a Windows system and crack a few passwords from there. We're going to look at dictionary attacks, which use a dictionary file, and brute force attacks, which use every potential combination of letters, numbers, and special characters. And remember, there are many hybrid attacks that mix these techniques in various ways, but we're just covering the basics here.
Let's start with a dictionary attack. We're going to use Cain, a popular program that's also known as Cain and Abel. When you install Cain and Abel, Windows will give you all types of warning messages. You'll have to disable your Windows Firewall and your antivirus software. Your antivirus will most likely recognize Cain and Abel as malicious software and quarantine the files required for it to run.
Once you launch Cain and Abel, you'll see all your password cracking tools. We're going to go to the Cracker tab, up here. We're interested in the LM & NTLM hashes. Next, let's go up here and click on this plus sign to import hashes from our computer. Here, under Add NT Hashes, we can add hashes from our local system. We can also check this box to include password history hashes so that if users are required to change passwords every 30 or 45 days, previous password hashes are included during the import.
You can also import hashes from a text file. So, if you have access to another system, you could potentially collect hashes from that system, dump them into a text file, copy them to a USB device, and then load them here and attempt to crack the passwords. You can also import from a SAM database by checking this, here.
Right now, we're just going to import hashes from our local system. You can see that it just loaded all the local accounts I have on this system. If you see "empty" under NT passwords, that means that there's no password for that account. If that field is blank, that means that a password is assigned to the account.
We're going to use a dictionary attack to see if we can retrieve the password for the Mrs. Worley account. I'm going to right-click on that account, hover over Dictionary Attack, and go to NTLM Hashes. Now I'm going to go up into this white space, right-click, and select Add to list.
Before I started this demo, I downloaded a list of passwords from the internet. This file is a list of ten thousand common passwords. It's estimated that thirty percent of all passwords are included in this list. If you look down here, you can see that it's going to scan for passwords.
If we check this box, here, it will look for the exact password. So, if my password is cat, that's what it's going to look for. Below that, it will reverse that password--so, instead of c-a-t, it would look for t-a-c.
Double passwords are just a password typed in twice. You can also have it search for all-lowercase passwords, search for all-uppercase passwords, or even have it put in numbers that commonly replace letters in passwords. With all these combinations, we're really going to use a variation of tens of thousands of different passwords.
Let's click on Start. Depending on your computer's processor, memory, and capability, this process can take a very long time. To save time, I actually edited that file and deleted most of the passwords with this scan. You can see that the scan did finish, but it didn't find that password. That's a good thing; it means my password isn't a dictionary word. Since that didn't work, let's exit and try a brute force attack.

We'll right-click on Mrs. Worley's account, hover over Brute-Force Attack, and select NTLM Hashes. Here's a predefined attack. You can see that if I click here, we can add to our options. We only have lowercase letters and numbers. We also have lowercase with numbers and special characters. I have lowercase, uppercase, numbers, and special characters. I'm going to brute force from one to sixteen characters. This system is a virtual machine with a single processor and not much memory, so it's going to take a long time. Let's click Start and see what happens. Down here, on the left, you can see it's going to take years to cycle through every variation and crack this password. We don't have years and years to wait, so let's stop this process and try something else.

To crack the password faster, we need to customize our attack. I'll get rid of these characters. Let's say I was doing some shoulder surfing and happened to see that Mrs. Worley was typing in a password, and I noticed three things: I saw that she typed 'teache' and that she didn't use any letters from u to z. I also saw that her password wasn't very long. So, we're going to brute force with these letters and use 6 or 7 characters. We also know the first several letters of our password. Of course, you probably wouldn't have all this information. But to save time, I've made these adjustments. I'll go ahead and click Start, and it will attempt to crack this password. You can see it's going to take a few minutes to complete, so I'll pause the demo and let the attack run.

Okay, our scan has completed in just under three minutes. You can see that the password it found was the word "teacher." Of course, knowing the first several letters of the password, like we did here, isn't common. I simplified the attack for time's sake. But it's often possible to gather enough information to brute force a password in a few days or even hours.

Okay, that's it for this demo. In this demo, we introduced John the Ripper and used it to crack a Linux password. Then we switched over to a Windows system and used Cain and Abel to crack a Windows-based password. You can see how, if users leak a little information or use easy passwords, hacking tools can get you into restricted systems and files in no time.

6.6.6 Crack Password Protected Files (Demo Video)

Transcript:

Password-protected files are extremely common, but they're not 100 percent secure. Some files natively support password protection, like PDFs. Other types of files are easy to store in a password-protected zip archive. Today, we're going to extract the password hash from these kinds of files and use John the Ripper to crack the hash. As a reminder, John the Ripper only works with hashes. It doesn't natively know how to work directly with password-protected files, so we need to extract the hash from the file we're interested in.

The process of extracting a hash is similar for most files. The toolkit provided with John the Ripper provides many scripts, but some of them aren't included on Kali Linux by default. We can obtain these tools by cloning the project from GitHub, but I've already downloaded the tools we need. Let's extract the hashes from the zip file we're interested in.

I'll open a terminal and go to the Documents directory. I'll list the folder contents to see what we have in there. I have a file called protected.zip. This is the zip file we'll attempt to crack the password on. We also have a wordlist that we'll use called words.txt.

Most tools that exist to help us extract hashes from files follow the standard for file type, in this case, zip followed by the number 2 and the word "john". So, I'll type, 'zip2john'. This makes it easier to remember what command we need. These tools output the hash straight to the screen, so we use the angle bracket to redirect that output to a file. We will finish our command with 'protected.zip > ziphash'.

Now that we have the hash for the zip file, we can crack it with John the Ripper. We need to specify the format of the hash, the file name, and the wordlist we want to facilitate cracking the hash. So, I'll type, 'john - -format=pkzip ziphash - -wordlist=words.txt'. We have the password. It's a variation of the word password. Now, let's extract the zipped file with that password!

I'll do that from the command line by typing 'unzip protected.zip'. It prompts for the password, so I'll type in the password that we just cracked. I get a message that the file is inflating. Let's list the folder contents. Now I see another file called password.pdf.

This is a PDF file that's also password-protected, so whoever set this up was really concerned about this document's security. If this PDF's password is just as weak as the first one, we can crack it, too. Let's go ahead and do that now. Getting the hash from the PDF is pretty much the same process as getting the hash from the zipped file. Let's type 'pdf2john password.pdf > pdfhash' and press Enter.

Now let's crack the password, just like we did for the zipped file password, by typing 'john - -format=pdf pdfhash - -wordlist=words.txt' and pressing Enter. There's the password! It's the word 'secret". Let's try it to make sure it works. I'll go to my Documents folder and open the PDF. It prompts me for a password, so I'll type in 'secret', and my file opens up.
And that's all there is to it. In this demo, we talked about extracting hashes from password-protected files. We extracted hashes from a zip file and then a PDF file. Then we used John the Ripper to crack those hashes.

6.6.7 Crack a Password with John the Ripper (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You've received a zip file that contains sensitive password-protected files. You need to access these files. The zip file is located in the home directory.

In this lab, your task is to use John the Ripper to:

- Crack the root password on the Linux computer named Support.
- Crack the password of the **protected.zip** file located in the home directory on IT-Laptop.

After John the Ripper cracks the password, it will not crack it again. The results are stored in the john.pot file.

Explanation

Complete this lab as follows:

1. View the current John the Ripper password file.
    a. From the Favorites bar, select **Terminal** .
    b. At the prompt, type **cd /usr/share/john** and press **Enter** .
    c. Type **ls** and press **Enter** .
    d. Type **cat password.lst** and press **Enter** to view the password list.
    e. Type **cd** and press **Enter** to go back to the root.
2. Crack the root password on the Support computer.
    a. Type **john /etc/shadow** and press **Enter** . The password is shown. Can you find it?
    b. Type **john /etc/shadow** and press **Enter** to attempt to crack the Linux passwords again. Notice that it does not attempt to crack the password again. The cracked password is already stored in the john.pot file.
    c. Use alternate methods of viewing the previously cracked password.
        - Type **john /etc/shadow --show** and press **Enter** .
        - Type **cd .john**
        - **cat john.pot** and press **Enter** to view the contents of the john.pot file.
    d. From the top right, select **Answer Questions** .
    e. Answer Question 1.
    f. Minimize the Lab Questions dialog.
3. Open a terminal on the IT-Laptop.
    a. From the top left, select **Floor 1 Overview** .
    b. Under IT Administration, select **IT-Laptop** .
    c. From the Favorites bar, select **Terminal** .
4. Export the contents of the protected.zip file to a text file.
    a. At the prompt, type **ls** and press **Enter** .
    Notice the protected.zip file you wish to crack.
    b. Type **zip2john protected.zip > ziphash.txt** and press **Enter** .
    c. Type **cat ziphash.txt** and press **Enter** to confirm that the hashes have been copied.
5. Using the text file, crack the password of the protected.zip file.

a. Type **john --format=pkzip ziphash.txt** and press **Enter** to crack the password. The password is shown. Can you find it?
b. Type **john ziphash.txt --show** and press **Enter** to show the previously cracked password.
c. From the top right, select **Answer Questions** .
d. Answer Question 2.
e. Select **Score Lab** .

6.6.8 Practice Questions (Section Quiz)

q_pwd_attacks_brute_01_secp8

Which of the following is MOST vulnerable to a brute-force attack?

Answers:

- ***Password authentication**
- Biometric authentication
- Two-factor authentication
- Challenge-response token authentication

Explanation:

Password authentication is the most vulnerable to a brute-force attack. The brute-force attack itself may take a considerable amount of time, especially if the attack is against a single user account or online login prompt rather than a localized copy of a security account's database. However, once the attack is complete, the attacker has all they need to log into the secured system.

The following authentication types were designed to avoid brute-force attacks and are much less vulnerable to a brute-force attack than password authentication:

- Biometric authentication is a cybersecurity process that verifies a user's identity using unique biological traits such as fingerprints, voices, retinas, and facial features. Biometric authentication systems store this information in order to verify a user's identity when that user accesses their account.
- Two-factor authentication (2FA) is a security system that requires two separate, distinct forms of identification in order to access something. The first factor is a password, and the second commonly includes a text with a code sent to your smartphone or some type of biometrics.
- Challenge-response authentication is a set of protocols used to protect digital assets and services from unauthorized users, programs, or activities. While challenge-response authentication can be as simple as a password, it is often something more complex or dynamic, such as a randomly generated request.

q_pwd_attacks_brute_02_secp8

You are using a password attack that tests every possible keystroke for every single key in a password until the correct one is found.

Which of the following technical password attacks are you using?

Answers:

- Keylogger
- Pass-the-hash attack
- ***Brute force attack**
- Password sniffing

Explanation:

In a brute force attack, every password is eventually found because the technique is to test every possible keystroke for every single key in a password until the correct one is found.

Keyloggers log or record every keystroke on the computer keyboard to obtain passwords and other important data.

A pass-the-hash attack is a hacking technique where an attacker uses an underlying NTLM or hash of a user's password to gain access to a server without ever using the actual plaintext password.

Password sniffing is a passive way for attackers to gain access to an account. The sniffer collects data that is in transit in a LAN. If access is gained on one system in a LAN, data can be gathered from data being sent from any other system in the network. The sniffer runs in the background, making it undetectable.

q_pwd_attacks_brute_03_secp8

An organization is experiencing an attack where the attackers break into the premises or cabinets by forcing a gateway or locks.

What BEST describes the observed attack?

Answers:

- ***Brute force**
- Downgrade
- Collision
- Birthday

Explanation:

A brute force physical attack can include smashing a hardware device to perform physical denial-of-service (DoS) or breaking into the premises or cabinets by forcing a gateway or locks.

A downgrade attack is a cryptographic attack that forces a server or client to use a lower specification protocol with weaker ciphers and key lengths.

A collision attack is a cryptographic attack where a weak cryptographic hashing function or implementation allows the generation of the same digest value for two different plaintexts.

A birthday attack is a cryptographic attack that exploits weaknesses in the mathematical algorithms used to encrypt passwords. It takes advantage of the probability of different password inputs producing the same encrypted output.

q_pwd_attacks_brute_04_secp8

While on patrol, a security guard discovers signs of forced entry on a window leading into the HVAC control room. Upon closer examination, the security guard notices hardly any lights or sounds of machinery working in the room.

These are indicators of what type of attack?

Answers:

- ***Brute force**

- On-path
- Distributed denial-of-service
- Network

Explanation:

A brute force attack is an attack against a physical aspect of a facility containing the physical hardware. Forcing a window and damaging HVAC equipment are excellent indicators of a brute force attack.

An on-path attack is where a malicious attacker can place themselves between two recipients to intercept messages sent via the network.

A distributed denial-of-service (DDoS) attack consumes a system's resources, so legitimate requests cannot go through.

A network-based attack comes over the network and does not require being physically present at the hardware's location to interfere with it.

q_pwd_attacks_dumpster_secp8

You are cleaning your desk at work. You toss several stacks of paper in the trash, including a sticky note with your password written on it.

Which of the following types of non-technical password attacks have you enabled?

Answers:

- Shoulder surfing
- Social engineering
- ***Dumpster diving**
- Password guessing

Explanation:

Dumpster diving relies on finding sensitive information that has been discarded in garbage cans, dumpsters, or other unsecured places that create access for attackers.

Shoulder surfing is watching and recording a password, pin, or access code that is being entered by someone nearby.

Social engineering relies on human error. It works by feigning trustworthiness to convince someone to give the attacker access.

Password guessing happens when someone is able to easily guess a password, typically because it is very common, like a pet's name or a hobby.

q_pwd_attacks_imperson_secp8

Carl receives a phone call from a woman who states she is calling from his bank. She tells him that someone has tried to access his checking account, and she needs him to confirm his account number and password to discuss further details. He gives her his account number and password.

Which of the following types of non-technical password attack has occurred?

Answers:

- Shoulder surfing
- ***Social engineering**
- Dumpster diving
- Password guessing

Explanation:

Social engineering relies on human error. It works by feigning trustworthiness to convince someone to share information.

Shoulder surfing is watching and recording a password, pin, or access code that is being entered by someone nearby.

Dumpster diving relies on finding sensitive information that has been discarded in garbage cans, dumpsters, or other unsecured places that create access for attackers.

Password guessing happens when someone is able to easily guess a password, typically because it is very common, like a pet's name or a hobby.

q_pwd_attacks_offline_secp8

A hacker successfully exfiltrates a database of user passwords and attempts to gain access to it as the hacker can now go around the authentication system.

What type of attack has the hacker achieved?

Answers:

- Password spraying
- Brute force
- Dictionary
- ***Offline**

Explanation:

An offline attack means the hacker has obtained a database of password hashes. The hacker can then perform attacks against this offline database in an attempt to compromise the encryption.

Password spraying is a horizontal brute force online attack. In password spraying, the hacker chooses one or more common passwords and tries them in conjunction with multiple usernames.

A brute force attack attempts every possible combination in the output space to match a captured hash and derive the plaintext that generated it.

A dictionary attack occurs when there is a good chance of guessing the likely value of the plaintext, such as an uncomplicated password.

q_pwd_attacks_pass_crack_secp8

You want to check a server for user accounts that have weak passwords.

Which tool should you use?

Answers:

- ***John the Ripper**
- Retina
- OVAL
- Nessus

Explanation:

John the Ripper is a password-cracking tool. Password crackers perform cryptographic attacks on passwords. Use a password cracker to identify weak passwords or passwords protected with weak encryption.

Nessus and Retina are vulnerability scanners. While vulnerability scanners check for default user accounts and often check for accounts with blank passwords, they typically do not include password-cracking features to test for weak passwords.

The Open Vulnerability and Assessment Language (OVAL) is an international standard for testing, analyzing, and reporting the security vulnerabilities of a system.

q_pwd_attacks_rainbow_01_secp8

Which of the following password attacks uses preconfigured matrices of hashed dictionary words?

Answers:

- Dictionary attack
- Brute-force attack
- Hybrid attack
- ***Rainbow table attack**

Explanation:

A rainbow table attack applies hashing algorithms to every word in a dictionary (sometimes including hybrids or passwords accumulated in brute force techniques). The algorithm then saves the results in a table or matrix. An encrypted password is compared to the pre-computed hashed passwords in the matrix until a match is found.

A dictionary attack tries known words (such as from a dictionary).

A brute force attack works through all possibilities until the password is cracked.

A hybrid attack adds appendages to known dictionary words (for example, 1password, password07, and p@ssword1).

q_pwd_attacks_rainbow_02_secp8

Which of the following strategies can protect against a rainbow table password attack?

Answers:

- ***Add random bits to the password before hashing takes place.**
- Encrypt the password file with one-way encryption.
- Educate users to resist social engineering attacks.
- Enforce strict password restrictions.

Explanation:

Some authentication protocols send password hashes between systems during the authentication process. Rainbow table attacks apply hashing algorithms to every word in a dictionary (sometimes including hybrids or passwords accumulated in brute force techniques) in an attempt to match hashed passwords. To protect against this type of attack, you can salt the hash by adding random bits to the password before hashing takes place, thereby producing an entirely different hash value for the password. Because the hacker does not know the extra random bits, the rainbow table is of no value.

The password file should be encrypted. Rainbow attacks do not work by accessing the password file but by capturing hashed passwords being transmitted on the network.

Users should be educated about social engineering attacks, but there is no connection between social engineering and rainbow table attacks.

Enforcing strict password restrictions might actually weaken network security if you do not educate users about proper procedures that protect login credentials.

q_pwd_attacks_rainbow_03_secp8

Jack is tasked with testing the password strength for the users of an organization. He has limited time and unlimited storage space.

Which of the following would be the BEST password attack for him to choose?

Answers:

- ***Rainbow attack**
- Dictionary attack
- Brute-force attack
- Keylogger attack

Explanation:

Rainbow attacks are like dictionary attacks, but instead of endlessly testing dictionary lists, they use tables precomputed with word lists and their hashes. This is much quicker than a dictionary attack or a brute-force attack. The biggest drawback to rainbow tables is their size. A single table can range from 30 gigabytes to over 300.

In a dictionary attack, word lists often taken straight from dictionaries are tested against password databases. Besides all the standard words you find in a dictionary, these lists usually include variations on words that are common for passwords, like using the word pa$$word. Lists can also include simple keyboard finger rolls, like q-w-e-r-t1234. The downside to this attack is this process can take a very long time.

In a brute-force attack, every possible keystroke is tested for each single key in a password until the correct one is found. The disadvantages of this type of attack are that it takes a huge amount of processing power to execute and it is very time-consuming.

Keyloggers record every stroke on the computer keyboard. Still, they must either be installed manually on each computer with the hardware option, or every user has to open an email attachment to install the software option. Both processes are very time-consuming.

q_pwd_attacks_salting_secp8

Which of the following techniques involves adding random bits of data to a password before it is stored as a hash?

Answers:

- Password sniffing
- Pass-the-hash attack
- ***Password salting**
- Keylogging

Explanation:

Password salting is adding random bits of data to a password before it is stored as a hash, making password cracking much more difficult.

Password sniffing is a passive way for attackers to gain access to an account. The sniffer collects data that is in transit in a LAN.

A pass-the-hash attack is a hacking technique where an attacker uses an underlying NTML or hash of a user's password to gain access to a server without ever using the actual plaintext password.

Keylogging is recording every stroke on the computer keyboard.

q_pwd_attacks_shoulder_secp8

Which of the following BEST describes shoulder surfing?

Answers:

- Guessing someone's password because it is so common or simple.
- Finding someone's password in the trash can and using it to access their account.
- Giving someone you trust your username and account password.
- ***Someone nearby watching you enter your password on your computer and recording it.**

Explanation:

Shoulder surfing is watching and recording a password, pin, or access code that is being entered by someone nearby.

Password guessing happens when someone is able to easily guess a password, typically because it is very common, like their pet's name or their hobby.

Dumpster diving relies on finding sensitive information that has been discarded in garbage cans, dumpsters, or other unsecured places that create access for attackers.

Social engineering relies on human error. It works by convincing someone to give the attacker access because they trick them into trusting them.

q_pwd_attacks_spraying_secp8

An organization notices an external actor trying to gain access to the company network. The attacker is not targeting a specific account but rather using the same password across a vast range of usernames in hopes that one might be correct.

What type of attack BEST describes this scenario?

Answers:

- ***Spraying**
- Brute force
- Rainbow table
- Dictionary

Explanation:

In a password spraying attack, the attacker tries a small number of commonly used passwords on many different accounts, attempting to bypass account lockouts that would generally affect brute-force attacks.

Brute-force attacks involve an attacker trying many passwords or passphrases with the hope of eventually guessing correctly. Brute-force attacks usually target one account.

Rainbow table attacks use precomputed tables for reversing cryptographic hash functions for cracking password hashes. They do not involve the widespread, low-frequency approach described in the scenario.

Dictionary attacks are typically applied to one account (or a small number of accounts) and are a parent of attacks like password attacks. However, it specifically mentions that the attack occurs across multiple accounts.

q_pwd_attacks_user_manipulation_secp8

Which social engineering technique involves the attacker interacting with the user to trick them into revealing their username and password?

Answers:

- Password guessing
- Physical access
- ***User manipulation**
- Dumpster diving

Explanation:

User manipulation is the correct answer. In user manipulation, the attacker interacts directly with the user, often pretending to be someone they trust, to trick them into revealing their username and password.

Password guessing involves the attacker trying to guess the user's password using default login information or publicly available information about the user. It does not involve direct interaction with the user.

Physical access involves the attacker gaining physical access to an office building or a user's workspace to look for written-down login information. It does not involve tricking the user into revealing their credentials.

Dumpster diving involves the attacker going through the user's trash to find discarded documents or information that might reveal the user's login information. It does not involve direct interaction with the user.

rainbow_table_01

What is the password for hash 202cb962ac59075b964b07152d234b70?

Answers:

- 123

rainbow_table_02

What is the password for hash 400238780e6c41f8f790161e6ed4df3b?

Answers:

- MaryHad_A_Sm@ll_Lamb

What is the password for hash 89BF04763BF91C9EE2DDBE23D7B5C730BDD41FF2?

Answers:

- DisneyL@nd3

rainbow_table_04

How many of the passwords found meet the company's password requirements?

Answers:

- 0
- ***1**
- 2
- 3

john_ripper_question1

What is the password for the root user of the Kali Linux computer?

Answers:

- 1worm4b8

john_ripper_question2

What is the password for the protected.zip file?

Answers:

- p@ssw0rd
- p@sswOrd

7.0 Vulnerability Management

7.1 Vulnerability Management

As you study this section, answer the following questions:

- Why is vulnerability management critical to cybersecurity strategy?
- In what ways do legacy and end-of-life systems increase the risk of vulnerabilities?
- What factors should be considered when conducting a vulnerability analysis?
- Why is reporting crucial for vulnerability management?
- How do threat feeds help with vulnerability management?

In this section, you will learn to:

- Explore end-of-life software/hardware

The key terms for this section include:

Term	Definition
Vulnerability management	Identifying and managing the risks to a network, including the operating system, applications, and other components of an organization's IT operations.
Vulnerability scan	Utilizes automated scanning processes to identify and evaluate potential issues.
Threat feed	Real-time, continuously updated sources of information about potential threats and vulnerabilities.
Penetration testing	We pay you to hack into systems to make sure people can't hack into systems (a very off quote from Sneakers).

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.1 Compare and contrast various types of security controls. • Control types ○ Compensating 2.3 Explain various types of vulnerabilities. • Operating system (OS)-based

- Hardware
    - Firmware
    - End-of-life
    - Legacy

4.3 Explain various activities associated with vulnerability management.

- Identification methods
    - Vulnerability scan
    - Threat feed
        - Open-source intelligence (OSINT)
        - Proprietary/third-party
        - Information-sharing organization
        - Dark web
    - Penetration testing
    - Responsible disclosure program
        - Bug bounty program
    - System/process audit
- Analysis
    - Confirmation
    - Prioritize
    - Common Vulnerability Scoring System (CVSS)
    - Common Vulnerability Enumeration (CVE)
    - Vulnerability classification
    - Exposure factor
    - Environmental variables
    - Industry/organizational impact
    - Risk tolerance
- Vulnerability response and remediation
    - Patching
    - Insurance
    - Segmentation
    - Compensating controls
    - Exceptions and exemptions
- Validation of remediation
    - Rescanning
    - Audit
    - Verification

4.4 Explain security alerting and monitoring concepts and tools.

- Tools
    - Vulnerability scanners

4.8 Explain appropriate incident response activities.

- Threat hunting

4.9 Given a scenario, use data sources to support an investigation.

- Data sources
    - Vulnerability scans

TestOut Security Pro	3.1 Harden computer systems 3.1.4 Configure Windows Update 5.2 Assessment techniques 5.2.3 Scan for vulnerabilities

7.1.1 Vulnerability Management (Lesson Video)

Transcript:

A vulnerability is a weakness that could be triggered accidentally or exploited intentionally to cause a security breach. Efficient vulnerability management plays a vital role in securing your organization's network. In this video, we'll discuss steps that can be taken to manage vulnerabilities effectively.

Let's start by looking at identification. Various sources can be used to identify vulnerabilities.
Vulnerability scans are automated tools that scan your system for known vulnerabilities. These scans comprehensively analyze your system's current security status, flagging any areas that require immediate attention or improvement.
Threat feeds provide real-time updates on cyber threats across the world. These feeds can provide information such as suspicious domains, known malware, known malicious IP addresses, and more. Security defenders can use this information to stay on top of the latest threats that might impact them.
Open-source intelligence gathers data from publicly available sources. At the same time, proprietary third-party feeds offer unique intelligence from private companies. Information-sharing organizations offer sector-specific threat intelligence. Dark web intelligence can also provide insights into underground criminal activities, including selling exploit codes and stolen data.
Penetration testing, often called "pen testing," is a simulated attack that can be used to test your defenses. They can help to detect security loopholes before malicious actors find them. A responsible disclosure program encourages external individuals to report vulnerabilities. Bug bounty programs take responsible disclosure one step further by offering recognition or compensation to individuals who report vulnerabilities. Lastly, system and process audits help to identify deviations from established policies. These audits can help to highlight non-compliance issues and pinpoint inefficiencies and opportunities for improvement in current processes.
Next is threat hunting. This involves proactively searching through networks to detect and isolate advanced threats evading security solutions. It's about being proactive instead of reactive, staying one step ahead instead of waiting for an attack to happen.
Threat hunting involves using automated and manual techniques to detect cyber threats. It begins with a hypothesis about a potential threat, which is then investigated using data analysis, system logs, and security tools. The goal is to detect hidden threats, understand the extent of any breaches, and identify ways to prevent further attacks. This proactive approach requires an in-depth understanding of an organization's network, including all internal and external connections, system configurations, and data flows. It also requires an understanding of current threat trends and tactics.
Automated tools can scan and monitor network traffic, but the human element is crucial in threat hunting. Cybersecurity professionals use their experience and intuition to interpret the data, identify anomalies, and track potential threats.
Once vulnerabilities have been identified, they must be analyzed to assess their potential impact. Vulnerability analysis helps prioritize remediation efforts by identifying the most critical vulnerabilities that pose the most significant risk to an organization.
Prioritization is typically based on factors such as a vulnerability's severity, the ease of exploitation, and the potential impact of an attack. Prioritizing vulnerabilities helps an organization focus limited resources on addressing the most significant threats first.
A standard ranking system is the Common Vulnerability Scoring System, or CVSS. The CVSS determines the vulnerability risk based on three metrics: base, temporal, and environmental. Base metrics describe a vulnerability's unique characteristics. Temporal metrics describe its changeable attributes, and environmental metrics tell what vulnerabilities are only present in specific environments or implementations.
Scan results often list the vulnerabilities by their CVE code. CVE stands for Common Vulnerabilities and Exposures. This is a free and publicly available list of standardized identifiers for known software vulnerabilities and exposures. There are currently 94 CVE numbering authorities from 16 countries, which provides a baseline for evaluation. CVE also provides

standardization, which allows data exchange for cybersecurity automation and aids professionals as they determine the best assessment tools for themselves.
Depending on the vulnerability analysis results, appropriate steps should be taken to mitigate the identified risks. Some standard remediation practices include patching, cybersecurity insurance, segmentation, and compensating controls.
Patching involves updating software or systems to fix security vulnerabilities. The process includes installing 'patches' or updates issued by software vendors to fix identified security loopholes. Cybersecurity insurance is a form of cover that offers a financial safety net in case of cyber-attacks or data breaches. It can cover costs associated with recovery, including incident response, data recovery, legal liability, and customer notification.
Segmentation refers to dividing a network into smaller parts or segments. By doing this, organizations can isolate parts of their network, limiting an attacker's ability to move laterally within the system. Compensating controls are alternative security measures implemented when a standard control isn't feasible. These controls help achieve the same security objective and reduce the risk to an acceptable level if the primary control cannot be implemented.
That's it for this lesson. In this lesson, we discussed vulnerability management. We talked about various methods that can be used for identifying vulnerabilities. We discussed how threat hunting, threat analysis, and threat response and remediation can play a vital role in securing an organization's network.

7.1.2 Vulnerability Type Facts

This lesson covers the following topics:

- Vulnerability management
- Device and operating system vulnerabilities
- Legacy and end-of-life (EOL) systems
- Firmware vulnerabilities

Vulnerability Management

Vulnerability management is critical to any organization's cybersecurity strategy, encompassing identifying, evaluating, treating, and reporting security vulnerabilities in operating systems, applications, and other components of an organization's IT operations. Vulnerability management may involve patching outdated systems, hardening configurations, or upgrading to more secure versions of operating systems. For applications, it might include code reviews, security testing, and updating third-party libraries.

Vulnerability scanning is a crucial component of this process, with specialized tools utilized to identify potential weaknesses in an organization's digital assets automatically. These tools scan for known vulnerabilities such as open ports, insecure software configurations, or outdated versions. Post scanning, analysis is performed to validate, classify, and prioritize the identified vulnerabilities for remediation based on factors such as the potential impact of a breach, the ease of exploiting the vulnerability, and the importance of the asset at risk. This continuous cycle of assessment and improvement helps organizations maintain safe and secure computing environments.

Device and Operating System Vulnerabilities

Operating systems (OS) are one of the most critical components of any infrastructure, so vulnerabilities in an OS can lead to significant problems when successfully exploited. Microsoft Windows has an extensive feature set and broad user base, especially among large organizations and governments. Its vulnerabilities often include buffer overflows, input validation problems, and privilege flaws typically exploited to install malware, steal information, or gain unauthorized access. Windows is an essential target for attackers because of its large install base. Large corporations and governments heavily depend upon it, which compounds the significance of its vulnerabilities.

Apple's macOS vulnerabilities often stem from its UNIX-based architecture, and weaknesses generally appear in access controls, secure boot processes, and third-party software. Apple macOS has a smaller user base than Windows, but its popularity has grown significantly. Generally, macOS is perceived as being 'safer' than other operating systems, which can lead to complacency.

Linux is a prevalent server OS but can also be used as a desktop or mobile OS. The open-source nature of Linux and the large community of active developers support rapid development. This generally results in quick identification and repair of vulnerabilities. Kernel vulnerabilities, misconfigurations, and unpatched systems are common issues in Linux. Despite its reputation for security, its widespread use in the cloud and server infrastructure makes Linux vulnerabilities especially significant.

The widespread adoption of Mobile OS like Android and iOS and their increasing use as primary computing platforms instead of traditional computers make them valuable targets for attack and exploitation. Android is open source, like Linux, resulting in similar benefits and problems. Additionally, Android OS is fragmented among different manufacturers and versions, resulting in inconsistent patching and update support. iOS, while not open source like Android, has also been impacted by several significant vulnerabilities.

The significance of OS vulnerabilities cannot be overstated, especially as specialized embedded systems, such as IoT, are added to our surroundings. Each system runs specialty operating systems and introduces vulnerabilities and potential pathways into corporate infrastructures.

Examples of OS vulnerabilities:

- **Microsoft Windows** — One of the most notorious vulnerabilities in Windows history was the MS08-067 vulnerability in Windows Server Service. This vulnerability allowed remote code execution if a specially crafted packet was sent to a Windows server. This vulnerability was exploited by the Conficker worm in 2008, which infected millions of computers worldwide. Additionally, MS17-010 represents a significant and critical security update released by Microsoft in March 2017. This update addressed multiple vulnerabilities in Microsoft's implementation of the Server Message Block (SMB) protocol (a network file-sharing protocol) that could allow remote code execution (RCE). These vulnerabilities, if exploited, could allow an attacker to install programs, view, change, or delete data, or create new accounts with full user rights.
- The significance of MS17-010 is tied closely to the EternalBlue exploit, which leveraged the vulnerabilities in early versions of the SMB protocol for malicious purposes. The most famous misuse of EternalBlue was during the WannaCry ransomware attack in May 2017, where it was used to propagate ransomware across networks worldwide, leading to massive damage and disruption. This event underlined the critical importance of timely system patching and reinforced the potential global impact of such vulnerabilities.
- **macOS** — In 2014, a significant vulnerability called "Shellshock" affected all Unix-based systems, including macOS. It allowed attackers to potentially gain control over a system due to a flaw in the Bash shell. Though it originated from a component in Unix systems, its impact was felt in macOS due to its Unix-based architecture.
- **Android** — The Stagefright vulnerability discovered in 2015 is a prominent example of Android. It allowed attackers to execute malicious code on an Android device by sending a specially crafted MMS message. This issue was particularly severe due to the ubiquity of the vulnerable component (the Stagefright media library) across Android versions and devices.
- **iOS** — In 2019, Google's Project Zero team discovered a series of vulnerabilities in iOS that nation-state attackers were abusing. These "watering hole" attacks took advantage of several vulnerabilities to gain full access to a device by having the victim visit a malicious website.
- **Linux** — The Heartbleed bug in 2014 was a severe vulnerability in many Linux systems' OpenSSL cryptographic software library. The vulnerability allowed attackers to read the system’s memory running the OpenSSL software's vulnerable versions, compromising the secret keys to protect data.

Additional concerns arise in mobile operating systems due to factors like the diversity of devices and operating system versions, bypassing operating system protections, and using apps downloaded outside official app stores. Identifying and managing vulnerabilities often involves keeping operating systems updated with the latest patches, hardening system configurations, carefully managing user privileges, and controlling software applications.

Legacy and End-of-Life Systems

Hardware vulnerabilities, particularly those associated with end-of-life and legacy systems, present considerable security challenges for many organizations, as patches or fixes for vulnerabilities are either unavailable or difficult to apply. End-of-life (EOL) and legacy systems share a common characteristic: they are both outdated. EOL systems may be legacy systems, and some are also EOL.

The manufacturer or vendor no longer supports EOL systems, so they do not receive updates, including critical security patches. This makes them vulnerable to newly discovered threats. Conversely, while still outdated, the vendor may still fully support legacy systems.

An EOL system is a specific product or version of a product that the manufacturer or vendor has publicly declared as no longer supported. It is also possible for open-source projects to be abandoned by the maintainers. An EOL system can be a hardware device, a software application, or an operating system. Products should be replaced or updated before they reach EOL status to ensure they remain supported by their vendors and receive critical security patches. Notable EOL product examples include the Windows 7 and Server 2008 operating systems, which stopped receiving updates in January 2020. These systems are significantly more vulnerable to attacks due to the absence of security patches for new vulnerabilities. Despite their EOL status, they are still in use in many environments.

Many devices (peripheral devices especially) remain on sale with known severe vulnerabilities in firmware or drivers and no possibility of vendor support to remediate them, especially in secondhand, recertified, or renewed/reconditioned marketplaces. Examples include recertified computer equipment, consumer-grade and recertified networking equipment, and various Internet of Things devices.

Legacy systems typically describe outdated software methods, technology, computer systems, or application programs that continue to be used despite their shortcomings. Legacy systems often remain in use for extended periods because the organization's leadership recognizes that replacing or redesigning them will be expensive or pose significant operational risks from complexity. The term "legacy" does not necessarily mean that the vendor no longer supports the system but rather that it represents hardware and software methods that are no longer popular and often incompatible with newer architectures or methods. Legacy systems often remain in use because they operate with sufficient reliability, have been incorporated into many critical business functions, and are familiar to long-tenured staff.

Assessing the risks associated with using EOL and legacy products, such as lack of updates, lack of support, and compatibility issues with newer systems, is crucial. EOL and legacy product replacements must continue to meet the organization's requirements, maintain compatibility with existing infrastructure, and support reliable data migration. Selection criteria must consider the availability of vendor support, device warranty details, and marketplace performance/reputation. Transitioning costs must be carefully assessed, too, including licensing, hardware upgrades, and professional service implementation fees. The work to transition away from EOL and legacy products must minimize disruptions and ensure long-term sustainability.

Firmware Vulnerabilities

Firmware is the foundational software that controls hardware and can contain significant vulnerabilities. For instance, the Meltdown and Spectre vulnerabilities identified in 2018 impacted almost all computers and mobile devices. The exposure was associated with the processors used inside the computer and allowed malicious programs to steal data as it was being processed. Another vulnerability, "LoJax," discovered in the Unified Extensible Firmware Interface (UEFI) firmware in 2018, enabled attackers to persist on a system even after a complete hard drive replacement or OS reinstallation. End-of-life (EOL) hardware vulnerabilities arise when manufacturers cease providing product updates, parts, or patches to the firmware.

7.1.3 Vulnerability Identification Methods Facts

This lesson covers the following topics:

- Vulnerability scan
- Threat feed
- Other vulnerability identification methods

Vulnerability Scan

Vulnerability scanning is a fundamental task within a vulnerability management program. It utilizes automated scanning processes to identify and evaluate potential issues. Vulnerability scans focus on networks, operating systems, applications, and other functional areas to detect known vulnerabilities, including insecure configurations, outdated software versions, or missing security patches. Regular scanning is required to maintain an accurate picture of an organization's security posture and to identify new vulnerabilities.

Threat feeds play a vital role in enhancing the effectiveness of vulnerability management by providing real-time information about emerging threats and newly discovered vulnerabilities. Threat feeds aggregate data from various sources, including cybersecurity researchers, vendors, and global security communities. These are integrated into vulnerability scanning tools to improve their detection capabilities. By leveraging threat feeds, organizations can stay ahead of the threat landscape, enabling them to prioritize and address the most critical vulnerabilities before attackers can exploit them.

Threat Feed

Another essential element of vulnerability management is the use of threat feeds. These are real-time, continuously updated sources of information about potential threats and vulnerabilities, often gathered from multiple sources. By integrating threat feeds into their vulnerability management practices, organizations can stay aware of the latest risks and respond more swiftly.

Threat feeds are pivotal in vulnerability scanning by providing real-time, continuous data about the latest vulnerabilities, exploits, and threat actors. These feeds serve as a valuable resource for enhancing the organization's threat intelligence and enabling quicker identification and remediation of potential vulnerabilities. They integrate data from various sources, including security vendors, cybersecurity organizations, and open-source intelligence, to comprehensively view the threat landscape.

Common threat feed platforms include AlienVault's Open Threat Exchange (OTX), IBM's X-Force Exchange, and Recorded Future. These platforms gather, analyze, and distribute information about new and emerging threats, providing actionable intelligence that can be incorporated into an organization's vulnerability management practices and sometimes directly into security infrastructure tools to provide up-to-the-minute protections.

Threat feeds significantly improve vulnerability identification by providing timely information and context about new threats that traditional vulnerability scanning does not provide. Threat feeds offer information that helps organizations focus their remediation efforts on the most relevant and potentially damaging vulnerabilities first. This proactive approach can significantly reduce the time between discovering a vulnerability and its remediation, thus minimizing the organization's exposure to potential attacks.

The following table describes several types of threat feeds:

Threat intelligence platforms and feeds are supplied as one of three different commercial models:

Threat Feed Type	Description
Third-party threat feeds	Open-source and proprietary threat feeds provide valuable real-time information on the latest cyber threats and vulnerabilities. Both feed types aggregate data from various sources and can be integrated into an organization's security infrastructure, contributing to a proactive cybersecurity strategy. The choice between open-source and proprietary threat feeds often comes down to essential attributes. Open-source feeds, such as those provided by the Cyber Threat Alliance or the MISP threat-sharing platform, are typically free and accessible to all, making them a cost-effective solution for smaller organizations or those with limited budgets. However, they may lack the depth, breadth, or sophistication of analysis found in proprietary feeds. Proprietary threat feeds often provide more comprehensive information and advanced analytic insights. However, these feeds come at a cost, and the return on investment will depend on an

Threat Feed Type	Description
	organization's specific needs, risk profile, and resources. Some organizations may use a combination of both open-source and proprietary feeds to achieve a balance of cost and coverage. The outputs from the primary research undertaken by threat data feed providers and academics can take three main forms: • Behavioral Threat Research — is narrative commentary describing examples of attacks and TTPs gathered through primary research sources. • Reputational threat intelligence — is lists of IP addresses and domains associated with malicious behavior, plus signatures of known file-based malware. • Threat Data — is computer data that can correlate events observed on a customer's networks and logs with known TTP and threat actor indicators. Threat data can be packaged as feeds integrating with a security information and event management (SIEM) platform. These feeds are usually described as cyber threat intelligence (CTI) data. The data is not a complete security solution; the threat data must be correlated with observed data from customer networks to produce actionable intelligence. This type of analysis is often powered by the SIEM's artificial intelligence (AI) features. • Closed/proprietary — is where threat research and CTI data are available as a paid subscription to a commercial threat intelligence platform. The security solution provider will also make the most valuable research available early to platform subscribers through blogs, white papers, and webinars. Some examples of such platforms include the following: ◦ IBM X-Force Exchange (exchange.xforce.ibmcloud.com) ◦ Mandiant's FireEye (mandiant.com/advantage/threat-intelligence) ◦ Recorded Future (recordedfuture.com/platform/threat-intelligence)
Open-source intelligence	Open-source intelligence (OSINT) describes collecting and analyzing publicly available information and using it to support decision-making. In cybersecurity operations, OSINT is used to identify vulnerabilities and threat information by gathering data from many sources such as blogs, forums, social media platforms, and even the dark web. This can include information about new types of malware, attack strategies used by cybercriminals, and recently discovered software vulnerabilities. Security researchers can use OSINT tools to automatically collect and analyze this information, identifying potential threats or vulnerabilities that could impact their organization. Some standard OSINT tools include Shodan for investigating internet-connected devices, Maltego for visualizing complex networks of information, Recon-ng for web-based reconnaissance activities, and theHarvester for gathering emails, subdomains, hosts, and employee names from different public sources.
Information-sharing organization	Threat feed information-sharing organizations are collaborative groups that exchange data about emerging cybersecurity threats and vulnerabilities. These organizations collect, analyze, and disseminate threat intelligence from various sources, including their members, security researchers, and public sources. Members of these organizations, often composed of businesses, government entities, and academic institutions, can benefit from the shared intelligence by gaining insights into the latest threats they might not have access to individually. They can use this information to fortify their systems and respond swiftly to emerging threats. Examples of such organizations include the Cyber Threat Alliance and the Information Sharing and Analysis Centers (ISACs), which span various industries. These organizations are crucial in enhancing collective cybersecurity resilience and promoting a collaborative approach to tackling cyber threats.

Threat Feed Type	Description
Deep and dark web	Threat research is a counterintelligence gathering effort in which security companies and researchers attempt to discover modern cyber adversaries' tactics, techniques, and procedures (TTPs). There are many companies and academic institutions engaged in primary cybersecurity research. Security solution providers with firewall and antimalware platforms derive much data from their customers' networks. As they assist customers with cybersecurity operations, they can analyze and publicize TTPs and their indicators. These organizations also operate honeynets to observe how hackers interact with vulnerable systems. The deep web and dark web are also sources of threat intelligence. The deep web is any part of the World Wide Web not indexed by a search engine. This includes pages that require registration, pages that block search indexing, unlinked pages, pages using nonstandard DNS, and content encoded nonstandardly. Within the deep web are areas that are deliberately concealed from "regular" browser access. • Dark net — is a network established as an overlay to internet infrastructure by software, such as The Onion Router (TOR), Freenet, or I2P, that acts to anonymize usage and prevent a third party from knowing about the existence of the network or analyzing any activity taking place over the network. Onion routing, for instance, uses multiple layers of encryption and relays between nodes to achieve this anonymity. • Dark web — websites, content, and services accessible only over a dark net. While there are dark web search engines, many sites are hidden from them. Access to a dark website via its URL is often only available via "word of mouth" bulletin boards. Investigating these dark websites and message boards is a valuable source of counterintelligence. The anonymity of dark web services has made it easy for investigators to infiltrate the forums and web stores set up to exchange stolen data and hacking tools. As adversaries react to this, they set up new networks and ways of identifying law enforcement infiltration. Consequently, dark nets and the dark web represent a continually shifting landscape. Please note that participating in illegal dark web activities is strictly prohibited. To stay safe, it is essential to exercise caution and follow legal and ethical guidelines when exploring the dark web. The dark web is generally associated with illicit activities and illegal content but has legitimate purposes. • Privacy and Anonymity — The dark web provides a platform for enhanced privacy and anonymity. It allows users to communicate and browse the internet without revealing their identity or location. It can be valuable for whistleblowers, journalists, activists, or individuals living under repressive government regimes. • Access to Censored Information — In countries with strict internet censorship, the dark web can be an avenue for accessing information that is otherwise blocked or restricted. It enables individuals to bypass censorship and access politically sensitive or controversial content. • o Research and Information Sharing — Some academic researchers or cybersecurity professionals may explore the dark web to gain insights into criminal activities and analyze emerging threats to improve cybersecurity operations.

Other Vulnerability Identification Methods

The following table reviews three additional vulnerability identification methods:

Method	Description
Penetration testing	Penetration testing, or pen testing, is a more aggressive approach to vulnerability management. Ethical hackers attempt to breach an organization's security in this practice, exploiting vulnerabilities to demonstrate their potential impact. While automated vulnerability scans and threat feeds are essential components of a robust security program, they may sometimes fail to identify specific vulnerabilities that a penetration test can uncover.
Bug bounties	Bug bounty programs are another proactive strategy and describe when organizations incentivize discovering and reporting vulnerabilities by rewarding external security researchers or "white hat" hackers. Both penetration testing and bug bounty programs are proactive cybersecurity practices to identify and mitigate vulnerabilities in a system or application. They both involve exploiting vulnerabilities to understand their potential impact, with the difference lying primarily in who conducts the testing and how it's structured. Penetration testing is typically performed by a hired team of professional ethical hackers within a confined time frame, using a structured approach based on the organization's requirements. This approach allows for a focused, in-depth examination of specific systems or applications and provides a predictable cost and timeline. In contrast, bug bounty programs open the testing process to a global community of independent security researchers. Rewards for finding and reporting vulnerabilities incentivize these researchers. This approach can bring diverse skills and perspectives to testing, potentially uncovering more complex or obscure vulnerabilities. An organization may choose penetration testing for a more controlled, targeted assessment, especially when testing specific components or meeting certain compliance requirements. A bug bounty program might be preferred when seeking a more extensive range of testing, leveraging the collective skills of a global community. However, many organizations see the value in both and use a combination of pen testing and bug bounty programs to ensure comprehensive vulnerability management. Responsible disclosure programs are established by organizations to encourage individuals to report security vulnerabilities in software or systems, allowing the organization to address and fix these vulnerabilities before they can be exploited maliciously. Responsible disclosure programs provide guidelines and procedures for reporting vulnerabilities and often reward or recognize individuals who responsibly disclose verified security issues.
Auditing	Auditing is an essential part of vulnerability management. Where product audits focus on specific features, such as application code, system/ process audits interrogate the wider use and deployment of products, including supply chain, configuration, support, monitoring, and cybersecurity. Security audits assess an organization's security controls, policies, and procedures, often using standards like ISO 27001 or the NIST Cybersecurity Framework as benchmarks. These audits can identify technical vulnerabilities and operational weaknesses impacting an organization's security posture. Cybersecurity audits are comprehensive reviews designed to ensure an organization's security posture aligns with established standards and best practices. There are various types of cybersecurity audits, including compliance audits, which assess adherence to regulations like GDPR or HIPAA; risk-based audits, which identify potential threats and vulnerabilities in an organization's systems and processes; and technical audits, which delve into the specifics of the organization's IT infrastructure, examining areas like network security, access controls, and data protection measures. Penetration testing fits into cybersecurity audit practices as a critical component of a technical audit as it provides a practical assessment of the organization's defenses by simulating real-world attack scenarios. Rather than simply evaluating policies or configurations, penetration tests seek exploitable vulnerabilities, providing a clear picture of what an attacker might achieve. The findings from these tests are then used to improve the organization's security controls and mitigate identified risks. Penetration tests also play an important role in compliance audits, as many regulations require organizations to conduct regular penetration testing as part of their cybersecurity program. For instance, the Payment Card Industry Data Security Standard (PCI DSS) mandates annual and proactive penetration tests for organizations handling cardholder data.

7.1.4 Vulnerability Analysis and Remediation (Lesson Video)

Transcript:

Vulnerability analysis involves evaluating vulnerabilities for their potential impact and exploitability. Vulnerability analysis aids in vulnerability classification, categorizing vulnerabilities based on their characteristics, such as the type of system or application affected, the nature of the exposure, or the potential impact.

Vulnerability analysis also helps to prioritize remediation. Remediation describes how vulnerabilities are addressed to mitigate their potential risk. Prioritization is typically based on factors such as vulnerability severity, the ease of exploitation, and the potential impact of an attack. Prioritizing vulnerabilities helps an organization focus limited resources on addressing the most significant threats first.

Mitigation techniques include applying patches, changing configurations, updating software, or replacing vulnerable systems. When immediate remediation is impossible, compensating controls describe alternative plans to reduce the risk.

Verification that remediation efforts have been successful is accomplished via several methods, including re-scanning affected systems. Organizations can significantly improve their resilience against cyberattacks by carefully analyzing and remediating vulnerabilities.

Vulnerability response and remediation practices encompass various strategies and tactics, including patching, insurance, segmentation, compensating controls, exceptions, and exemptions, each playing a distinct role in managing and mitigating cybersecurity risks.

Patching is one of the most straightforward and effective remediation practices. It involves applying updates and patches to software or systems to fix known vulnerabilities. Patching helps prevent attackers from exploiting known vulnerabilities, improving an organization's security posture.

Cybersecurity insurance can provide financial protection if a security breach results from a vulnerability. It's another factor in vulnerability response. While insurance doesn't mitigate vulnerabilities directly, it's vital in a comprehensive risk management strategy, complementing technical controls with financial risk transfer.

Segmentation involves dividing a network into separate segments to contain potential security breaches. If an attacker exploits a vulnerability and gains access to one segment, they're confined to it. This prevents them from moving laterally across the entire network, limiting the impact of a successful attack and supporting incident response teams.

Compensating controls refer to measures put in place to mitigate the risk of a vulnerability when security teams can't directly eliminate it or when direct remediation isn't immediately possible.

Exceptions and exemptions describe scenarios where specific vulnerabilities can't be remediated due to business criticality, technical constraints, or cost constraints. In these cases, the senior leadership teams accept the risk and document the rationale for the decision, along with an established timeline for reassessment.

Validating vulnerability remediation is critical for several vital reasons. Validation ensures that the remediation actions have been implemented correctly and function as intended. Despite best intentions, human error or technical problems can frequently lead to incomplete or incorrect implementation of fixes. These issues go unnoticed without validation, exposing the organization to the same vulnerability it initially sought to address.

Validation can be achieved through re-scanning, auditing, or other verification forms. Re-scanning involves performing additional vulnerability scans after remediation actions have been implemented. The re-scan aims to determine if the vulnerabilities identified in the initial scan have been resolved. If the same vulnerabilities aren't identified in the re-scan, it strongly indicates that the remediation efforts were successful.

Auditing involves an in-depth examination of the remediation process by reviewing the steps taken to address the vulnerability and ensuring they align with the organization's policies and best practices. Audits verify that necessary documentation has been updated, such as records of identified vulnerabilities, remediation actions taken, and any exceptions or exemptions granted.

Verification is the process of confirming the results of the remediation actions. It involves various methods, including manual checks, automated testing, or reviews of system logs or other records. Verification ensures that remediation steps have been implemented correctly, function as intended, and don't introduce new issues or vulnerabilities.

That's it for this lesson. In this lesson, we discussed vulnerability analysis and remediation. We also talked about the importance of validating vulnerability remediation to ensure the fixes were effective.

7.1.5 Vulnerability Analysis and Remediation Facts

This lesson covers the following topics:

- Vulnerability analysis
- Validating vulnerability remediation
- Vulnerability reporting

Vulnerability Analysis

Vulnerability analysis supports several critical aspects of an organization's cybersecurity strategy, including prioritization, vulnerability classification, exposure considerations, organizational impact, and risk tolerance contexts.

Note the following considerations related to vulnerability analysis:

Consideration	Description
Prioritization	Vulnerability analysis prioritizes remediation efforts by identifying the most critical vulnerabilities in an organization. Prioritization is typically based on factors such as vulnerability severity, the ease of exploitation, and the potential impact of an attack. Prioritizing vulnerabilities helps an organization focus limited resources on addressing the most significant threats first.
Classification	Vulnerability analysis aids in vulnerability classification, categorizing vulnerabilities based on their characteristics, such as the type of system or application affected, the nature of the exposure, or the potential impact. Classification can help clarify the scope and nature of an organization's threats.
Exposure factor	Vulnerability analysis must also consider exposure factors like the accessibility of a vulnerable system or data and environmental factors like the current threat landscape or the specifics of the organization's IT infrastructure. These factors can significantly influence the likelihood of a vulnerability being exploited and directly impact its overall risk level. The exposure factor (EF) represents the extent to which an asset is susceptible to being compromised or impacted by a specific vulnerability. It helps assess the potential impact or loss if the vulnerability is exploited. Factors might include weak authentication mechanisms, inadequate network segmentation, or insufficient access control methods.
Impacts	Vulnerability analysis assesses the potential organizational impact of vulnerabilities. This could include financial loss, reputational damage, operational disruption, or regulatory penalties. Understanding this impact is crucial for making informed decisions about risk mitigation.
Environmental factors	Several environmental variables play a significant role in influencing vulnerability analysis. One of the primary environmental factors is the organization's IT infrastructure, which includes the hardware, software, networks, and systems in use. These components' diversity, complexity, and age can affect the number and types of vulnerabilities present. For instance, legacy systems may have known unpatched vulnerabilities, while new emerging technologies might introduce unknown vulnerabilities. The external threat landscape is another crucial environmental factor. The prevalence of certain types of attacks or the activities of specific threat actors can affect the likelihood of exploitation of particular vulnerabilities. For example, if ransomware attacks rise within the medical industry, that sector can prioritize those vulnerabilities. The regulatory and compliance environment is another significant factor. Organizations in heavily

Consideration	Description
	regulated industries, like healthcare or finance, may need to prioritize vulnerabilities that could lead to sensitive data breaches and result in regulatory penalties. The operational environment, including the organization's workflows, business processes, and usage patterns, can also influence vulnerability analysis. Certain operational practices increase exposure to specific vulnerabilities or affect the potential impact of a successful exploit. Examples include poor patch management practices, lack of rigorous access controls, lack of awareness training, poor configuration management practices, and insufficient application development policies.
Risk tolerance	Vulnerability analysis must align with an organization's risk tolerance. Risk tolerance refers to the level of risk an organization is willing to accept, which can vary greatly depending on the organization's size, industry, regulatory environment, and strategic objectives. By aligning vulnerability analysis with risk tolerance, an organization can ensure its vulnerability management efforts align with its overall risk management strategy.

Validating Vulnerability Remediation

Validating vulnerability remediation is critically essential for several key reasons. Validation ensures that the remediation actions have been implemented correctly and function as intended. Despite best intentions, human error or technical problems can frequently lead to incomplete or incorrect implementation of fixes. These issues go unnoticed without validation, exposing the organization to the same vulnerability it initially sought to address.

Validation helps confirm that the remediation has not inadvertently introduced new issues or vulnerabilities. For example, a patch may interfere with other software or systems, or a configuration change could expose new security gaps. Also, validation provides a measure of accountability, ensuring that responsible parties adequately address identified vulnerabilities. This is especially important in larger organizations where multiple teams or individuals may be involved in the remediation process.

- Re-scanning involves performing additional vulnerability scans after remediation actions have been implemented. The re-scan aims to determine if the vulnerabilities identified in the initial scan have been resolved. If the same vulnerabilities are not identified in the re-scan, it strongly indicates that the remediation efforts were successful.
- Auditing involves an in-depth examination of the remediation process by reviewing the steps taken to address the vulnerability and ensuring they align with the organization's policies and best practices. Audits verify that necessary documentation has been updated, such as records of identified vulnerabilities, remediation actions taken, and any exceptions or exemptions granted.
- Verification confirms the results of the remediation actions. It involves various methods, including manual checks, automated testing, or reviews of system logs or other records. Verification ensures that remediation steps have been implemented correctly, function as intended, and do not introduce new issues or vulnerabilities.

Vulnerability Reporting

Vulnerability reporting is a crucial aspect of vulnerability management and is critical in maintaining an organization's cybersecurity posture. A comprehensive vulnerability report highlights the existing vulnerabilities. It ranks them based on their severity and potential impact on the organization's assets, enabling the management to prioritize remediation efforts effectively.

The Common Vulnerability Scoring System (CVSS) provides a standardized method for rating the severity of vulnerabilities. It includes metrics such as exploitability, impact, and remediation level. By using CVSS, organizations can compare and prioritize vulnerabilities consistently.

Another essential practice is to include information about the potential impact of each vulnerability in the report. This could involve describing the possible outcomes of exploiting the vulnerability, including data breaches, system outages, or other operational impacts. It is essential to provide recommendations for addressing each vulnerability in the report. Recommendations might suggest specific patches or updates, recommend configuration changes, or identify other mitigation strategies.

Timely reporting is also essential, as delays in reporting can lead to delays in remediation and increase the window of opportunity for attackers. Vulnerability reports must use a clear, concise format that is easy for technical and non-technical stakeholders to understand to help ensure that the report is understood and that appropriate actions are taken in response.

7.1.6 Explore End of Life Software / Hardware (Demo Video)

Transcript:

End-of-life in regard to software means there's a date set when it will no longer receive any updates. This normally means there's a new version already out or going to be released, where developers will focus on the new version of the software versus the old. We're going to explore some ways to keep track of the end-of-life.

One good way to keep track of this is by finding information on the internet. When a piece of software will no longer be supported, the date will be published so tech administrators will know when an update is needed. One website we can check out is endoflife.date. As you can see, all sorts of different software companies are listed. Some of the most popular pages are listed here in the middle. Let's take a look at Windows Server.
After scrolling down, we can see that Windows Server 2012 R2 will reach the end-of-life starting on October 10, 2023. Although this version of Windows Server hasn't received full support since 2018, it has been getting regular security updates. If a software isn't receiving security updates, it could leave you vulnerable to hackers. That's why, in most cases, software will be listed as end-of-life when it no longer receives any updates. Now, the last window is what they call extended security updates. Usually, this involves paying a substantial amount of money to receive updates past the normal security support date. Once the extended date is reached, there are typically no more updates to that version of the software.
Let's look at one more example. Red Hat Enterprise Linux goes through a similar phase. There comes a time when full support isn't available. Full Support may entail bug fixes and features, while Maintenance Support typically includes security updates and some bug fixes. RHEL 7 will reach the end-of-life starting on June 30th, 2024. There's also an Extended Life Cycle Support up through June 30th, 2028. If you work in the tech industry, you should always be aware of the end-of-life dates set by the software you manage.
Another way to be informed about end-of-life software on your network is to scan your computers. Network scanners can scan computers and find what software may be installed on them. Here, you can see that the CentOS 6.9 server is a device that was scanned on our network; however, it's at the end-of-life since it's not supported by regular maintenance. Instead of going to each computer and looking at a list, this could be helpful. The same concept applies to software. Installed software could also be marked as end-of-life if it's no longer supported. This could mean there's a new version of the software out, or the developer who originally made it abandoned the project. One example is PuTTY. You can see it picked up version 0.79. If this same version were on other systems, you'd see multiple computers listed here. The version that's installed can be used as a comparison to the latest version released by the developer. Knowing what kind of operating systems and software are installed on your network is a significant step in keeping your network secure. That's it for this demo. In this demo, we showed you how to research end-of-life dates and how you can use a network scanner to discover information on your network.

7.1.7 Identify Types of Vulnerabilities

7.1.8 Practice Questions (Section Quiz)

q_vuln_type_android_sec8

You are a cybersecurity analyst at a tech company that develops mobile applications.

Your team has been informed of a significant vulnerability that affects mobile operating systems. The vulnerability allows unauthorized remote access to sensitive user data.

Which of the following operating systems should your team prioritize for patching and security updates, based on the information provided?

Answers:

- iOS
- Windows Mobile
- BlackBerry OS
- ***Android**

Explanation:

Android is the correct answer. Given the information provided in the question, the vulnerability affects mobile operating systems and Android is one of the most widely used mobile operating systems in the world. Therefore, prioritizing Android for patching and security updates would be the most effective strategy to protect the largest number of users.

iOS is a widely used mobile operating system, and while it's important to address vulnerabilities in iOS, the question does not specify that iOS is affected by this particular vulnerability. Therefore, prioritizing iOS would not be the most effective use of resources in this scenario.

Windows Mobile, while still in use in some places, has a much smaller market share compared to Android. Prioritizing Windows Mobile over Android, which has a larger user base, would not be the most effective strategy.

BlackBerry OS, like Windows Mobile, has a smaller market share and is not as widely used as Android. Therefore, prioritizing BlackBerry OS would not be the most effective use of resources.

q_vuln_type_eol_sec8

You are the IT Director at a mid-sized company. The company's core business operations rely on a legacy system that has recently reached its end-of-life (EOL).

The vendor no longer supports this system, and it has known security vulnerabilities. However, transitioning to a new system would be costly and time-consuming.

What is the BEST course of action?

Answers:

- Continue using the EOL system and hope that the known vulnerabilities won't be exploited.
- Immediately transition to a new system, regardless of the cost and disruption to business operations.
- ***Develop a detailed transition plan that includes a cost-benefit analysis, risk assessment, and timeline for transitioning to a new system.**
- Ignore the EOL status and continue operations as usual, as the system has been reliable so far.

Explanation:

Developing a detailed transition plan that includes a cost-benefit analysis, risk assessment, and timeline for transitioning to a new system is the best option. Developing a detailed transition plan allows the company to understand the costs, benefits, and risks associated with transitioning to a new system. This approach ensures that the company can make an informed decision and plan for a smooth transition that minimizes disruption to business operations.

Continuing to use the EOL system and hope that the known vulnerabilities won't be exploited is not advisable. Continuing to use an EOL system with known vulnerabilities exposes the company to significant security risks.

Immediately transitioning to a new system, regardless of the cost and disruption to business operations, while addressing the security concern, may not be the best course of action. An immediate transition without proper planning could lead to unforeseen costs, potential data loss, and disruption to business operations.

Ignoring the EOL status and continue operations as usual, as the system has been reliable so far, is not advisable. Ignoring the EOL status of a system is a risky approach. Even if the system has been reliable so far, the lack of vendor support and potential security vulnerabilities pose significant risks to the company.

q_vuln_type_firmware_sec8

A cyber consultant inspects a corporate desktop after receiving numerous complaints.

What type of vulnerability can include instances where processors inside the computer allow malicious programs to steal data during processing?

Answers:

- ***Firmware**
- Virtualization
- End-of-life
- Legacy

Explanation:

Firmware vulnerabilities include instances where processors inside the computer allow malicious programs to steal data during processing.

Virtualization vulnerabilities include virtual machine (VM) escape--when an attacker with access to a VM breaks out of this isolated environment and gains access to the host system or other VMs running on the same host.

An end-of-life (EOL) system vulnerability includes instances where a specific product or version of a product that the manufacturer or vendor publicly declares as no longer supported.

Legacy system vulnerabilities typically describe outdated software methods, technology, computer systems, or application programs with continued use despite known shortcomings.

q_vuln_type_legacy_01_sec8

A software engineer at a growing tech company identifies that some divisions in the organization still operate on legacy systems. The firmware for these systems has not seen updates in over a decade.

The chief information security officer (CISO) recognizes the imminent risks these outdated systems pose and decides to hold a training session. During the training, the software engineer asks about the main vulnerability of such systems.

Given the context of legacy and end-of-life system vulnerabilities, what is the primary risk of using firmware that has not received security updates, thus potentially exposing the system to breaches?

Answers:

- The firmware becomes faster and more efficient.
- The system can experience compatibility issues with newer software.
- ***Unauthorized access becomes easier for potential attackers.**
- The system may require frequent restarts due to firmware instability.

Explanation:

Non-updated legacy firmware remains unprotected from patches designed to rectify known vulnerabilities, making it an inviting target for attackers who can exploit these weak spots to achieve unauthorized system access.

Outdated firmware does not magically enhance its performance over time. In fact, as technology advances, it tends to become less compatible and loses efficiency when juxtaposed against its updated counterparts.

Compatibility issues pose challenges for legacy systems; however, when evaluated from a security standpoint, the foremost risk they present is the heightened susceptibility to potential security breaches.

While occasional system instability might contribute to aging firmware, this inconsistency does not measure up to the predominant security threat that outdated firmware poses regarding potential unauthorized penetrations.

q_vuln_type_legacy_02_sec8

What describes systems that create risk because they no longer receive critical security updates and patches?

Answers:

- ***Legacy system**
- Operating system
- Sandbox
- Thin client

Explanation:

A legacy system is an outdated computing software or hardware still in use. Legacy systems generally receive no support or maintenance.

An operating system is software that manages hardware while providing services for applications.

A sandbox is an isolated area created for testing and developing host and system environments. Administrators can use a sandbox to test patches and security controls before production.

A thin client is a low-power computer that runs from resources stored on a central server. A thin client connects remotely to a server-based computing environment that stores applications, data, and memory.

q_vuln_type_legacy_03_sec8

A cyber technician works on a corporate laptop where an employee complains the software is outdated.

What type of vulnerability describes continued use of outdated software methods, technology, computer systems, or application programs, despite known shortcomings?

Answers:

- ***Legacy**
- Firmware
- Virtualization
- End-of-life

Explanation:

Legacy system vulnerabilities typically describe the use of outdated software methods, technology, computer systems, or application programs despite known shortcomings.

Firmware vulnerabilities include instances where processors inside the computer allow malicious programs to steal data during processing.

Virtualization vulnerabilities include virtual machine (VM) escape--when an attacker with access to a virtual machine breaks out of this isolated environment and gains access to the host system or other VMs running on the same host.

An end-of-life (EOL) system vulnerability includes instances where a specific product or version of a product that the manufacturer or vendor has publicly declared as no longer supported.

q_vuln_type_os_01_sec8

You are the IT security manager at a large corporation. Your team has just discovered a significant vulnerability in the company's Linux-based server infrastructure. The vulnerability, if exploited, could allow an attacker to gain unauthorized access to sensitive data.

Your team has identified a patch that can fix the vulnerability, but applying the patch will require significant downtime during peak business hours.

What is the BEST course of action?

Answers:

- Apply the patch immediately during peak business hours to ensure the vulnerability is fixed as soon as possible.
- Wait until off-peak hours to apply the patch to minimize business disruption.
- Ignore the patch since Linux is known for its security and the likelihood of an attack is low.
- ***Inform the senior management about the vulnerability and the potential impact of the patch on business operations, and ask for their decision.**

Explanation:

Informing the senior management about the vulnerability and the potential impact of the patch on business operations is the best option. As the IT security manager, it's your responsibility to inform senior management about the vulnerability, the potential impact of an attack, and the potential impact of the patch on business operations. This allows the senior management to make an informed decision about how to proceed, taking into consideration both the security risk and the potential business impact.

Applying the patch immediately during peak business hours to ensure the vulnerability is fixed as soon as possible is not the best because it could disrupt business operations during peak hours. While it's important to fix vulnerabilities as soon as possible, it's also important to consider the impact on the business.

Waiting until off-peak hours to apply the patch to minimize business disruption might seem reasonable, but waiting to apply the patch could leave the system vulnerable to attacks. If an attacker were to exploit the vulnerability before the patch is applied, the consequences could be severe.

Ignoring the patch since Linux is known for its security and the likelihood of an attack is low is not advisable. Ignoring a known vulnerability, especially one that could allow unauthorized access to sensitive data, is not a good security practice, regardless of the perceived security of the operating system.

q_vuln_type_os_02_sec8

A large multinational corporation has recently discovered a significant vulnerability in their widely used operating system. The vulnerability could potentially allow unauthorized remote access to sensitive corporate data.

The corporation's IT team has been tasked with addressing this issue.

Which of the following approaches would be the most effective in managing this vulnerability?

Answers:

- Ignore the vulnerability since the operating system is due to be updated in the next six months.
- Inform all employees about the vulnerability and ask them to be extra vigilant.
- ***Implement a patch to fix the vulnerability and conduct a thorough system-wide security audit.**
- Disconnect all systems from the network until a new operating system can be installed.

Explanation:

Implementing a patch to fix the vulnerability is the most effective immediate response. This will close the security gap and protect the corporation's data. Conducting a thorough system-wide security audit will help identify any other potential vulnerabilities and ensure that the patch has been implemented correctly across all systems.

Ignoring the vulnerability is not a viable option. Even though the operating system is due to be updated, six months is a long time for a significant vulnerability to be left unaddressed. During this time, the corporation is at risk of a potential data breach, which could have severe financial and reputational consequences.

While it's important to inform employees about potential security threats, simply asking them to be extra vigilant is not enough. Employees may not have the technical knowledge or ability to protect their systems from a significant operating system vulnerability.

Disconnecting all systems from the network is an extreme measure that would likely disrupt business operations. While this might prevent external unauthorized access, it's not a practical or effective long-term solution. It also doesn't address the vulnerability itself, which would still be present when the systems are reconnected to the network.

q_vuln_type_prioritize_sec8

The security team at a major corporation has discovered multiple vulnerabilities during its latest assessment. The security manager must prioritize these vulnerabilities to ensure that the most critical ones get addressed first.

In the context of vulnerability management and prioritization, which of the following criteria are MOST crucial for the security manager to consider when determining the urgency of addressing a specific vulnerability?

Answers:

- ***The potential impact of the vulnerability on the organization's core operations**

- The age of the software containing the vulnerability
- The number of times the vulnerability has appeared in past assessments
- The popularity of the software among the organization's employees

Explanation:

Organizations primarily consider the potential operational impact when prioritizing vulnerabilities. They should urgently address exploitations that could cause severe operational disruptions, data breaches, or other significant problems.

Older software may be more vulnerable, but its age does not primarily dictate prioritization. Instead, the vulnerability's severity and potential impact hold greater importance.

Recurring vulnerabilities might highlight systemic problems, but the frequency of past identifications does not determine the vulnerability's criticality.

Although the popularity of software can show the extent of a vulnerability within an organization, it does not directly signify its severity or potential operational impact.

q_vuln_assess_bug_bounty_secp8

A medium-sized software development company recently introduced a bug bounty program to identify and mitigate vulnerabilities in their flagship application. The security manager plans to coordinate the program's rules and engagement policies.

When setting up a bug bounty program for vulnerability management, which activities should the security manager prioritize to ensure the program's effectiveness and ethical participation? (Select two.)

Answers:

- ***Establishing a clear scope of which assets researchers can test.**
- Offering substantial rewards regardless of the severity of the bug found.
- ***Providing a secure platform for researchers to report findings.**
- Allowing researchers to disclose findings publicly immediately after discovery.
- Providing valuable real-time information on the latest cyber threats and vulnerabilities.

Explanation:

Security managers must define the scope to guide researchers about which areas they can and cannot test, preventing unintended system breaches outside the bug bounty program's intention.

A bug bounty program requires a secure and straightforward method for researchers to report vulnerabilities effectively.

The program should set rewards based on the bug's severity and impact. Offering high rewards for minor issues might result in financial inefficiencies and not attract top-notch researchers.

Disclosing vulnerabilities publicly before applying a patch compromises the software's security. Well-structured bug bounty programs mandate researchers to delay public disclosures until addressing the vulnerability.

Open-source and proprietary threat feeds provide valuable real-time information on the latest cyber threats and vulnerabilities.

q_vuln_assess_dark_web_secp8

As a cybersecurity analyst, you are investigating a case of corporate espionage. You suspect that the perpetrator may have used the deep or dark web to access confidential information.

Which of the following would be a legitimate reason for someone to use the deep or dark web in a corporate setting?

Answers:

- To conduct illegal activities anonymously
- To bypass corporate network restrictions
- ***To access censored information**
- To avoid detection by law enforcement

Explanation:

To access censored information is the correct answer. In some situations, the deep or dark web can be used legitimately to access information that has been censored or is otherwise difficult to obtain. For example, a cybersecurity analyst might use the deep web to access information about emerging threats that is not available through traditional channels.

While the deep and dark web can provide anonymity, using it for illegal activities is not a legitimate reason in a corporate setting. Engaging in illegal activities can lead to severe consequences, including legal penalties and damage to the company's reputation.

While it's technically possible to use the deep and dark web to bypass network restrictions, this is not a legitimate or ethical use in a corporate setting. Network restrictions are typically in place for a reason, such as to protect the company's network and data.

While the deep and dark web can provide a degree of anonymity, using it to avoid detection by law enforcement is not a legitimate reason in a corporate setting. This could imply illegal activities, which are not acceptable in a corporate environment.

q_vuln_assess_disclosure_program_secp8

A system admin discovers a security vulnerability in a widely used software and brings it to the manager's attention, who said to fix it but has not released the information yet. The system admin releases the information anyway, as the company is part of a voluntary info-sharing organization.

What is the company a part of?

Answers:

- ***Responsible disclosure program**
- Bug bounty program
- Penetration testing
- Auditing

Explanation:

An organization's responsible disclosure program encourage individuals to report security vulnerabilities in software or systems, allowing organizations to address and fix these vulnerabilities before exploitation.

Corporations that sell software utilize a bug bounty program. They offer cash incentives to reveal vulnerabilities to them before the public so that the corporation can patch the vulnerability.

Penetration testing against a company's network ensures vulnerabilities are not readily exploitable. It does not deal with releasing information relating to vulnerabilities.

Auditing assesses an organization's security controls, policies, and procedures, often using standards like ISO 27001 or the NIST Cybersecurity Framework as benchmarks. They ensure a network's security against vulnerabilities unrelated to releasing information on vulnerabilities.

q_vuln_assess_osint_secp8

An IT administrator has reviewed security policies and best practices on well-known IT bulletin boards. During this reading, the admin became aware of several new vulnerability exploits.

What type of information is this?

Answers:

- ***Open-source intelligence**
- Information-sharing organizations
- Cyber threat intelligence
- Threat feeds

Explanation:

Open-source intelligence (OSINT) describes collecting and analyzing publicly available information and using it to support decision-making. OSINT identifies vulnerabilities and threat information by gathering data from many sources such as blogs, forums, social media platforms, and even the dark web.

Information-sharing organizations are groups composed of businesses, government entities, and academic institutions. Each member of an organization benefits from sharing information with the group members.

Cyber threat intelligence is investigating, collecting, analyzing, and disseminating information about emerging threats and threat sources.

Threat feeds are signatures and pattern-matching rules supplied to analysis platforms as an automated feed. Companies respond swifter to emergent threats, as threat feeds provide real-time information.

q_vuln_assess_penetration_testing_secp8

A large financial institution is considering outsourcing its IT infrastructure to a third-party cloud service provider. The company has concerns about the risks of giving its sensitive financial data to an external vendor.

What approach should the company use to ensure the vendor complies with the appropriate security standards and regulations?

Answers:

- Enter into a contract without clauses for regular assessments or audits of the vendor's security practices.
- Rely on the vendor's reputation in the industry without conducting any further assessments.
- ***Conduct penetration testing on the vendor's infrastructure or seek evidence that the vendor has performed regular penetration tests.**
- Prioritize the vendor's cost and ease of use over security considerations.

Explanation:

Penetration testing identifies potential vulnerabilities in a vendor's systems, networks, and applications, assessing their security posture. The company gains insights into the vendor's security resilience and vulnerabilities that attackers could exploit by conducting or requesting evidence of regular penetration tests.

Simply entering a contract without provisions for regular assessments or audits may be insufficient. Regular assessments and audits ensure ongoing adherence to security standards and compliance requirements.

Solely relying on the vendor's reputation may not offer a comprehensive and objective assessment of the vendor's current security practices and regulatory compliance.

While important, cost and ease of use should not take precedence over security considerations.

q_vuln_assess_proprietary_threat_feeds_secp8

Open-source threat feeds are an excellent tool for utilizing all companies with an online presence.

However, some companies use proprietary threat feeds for an additional cost due to more depth, breadth, and sophistication of analysis found herein.

What are the three primary forms these can take? (Select three.)

Answers:

- ***Behavioral threat research**
- ***Reputational threat intelligence**
- ***Threat data**
- Vulnerability management
- Dark net
- Dark web
- Bug bounties

Explanation:

The following are the three primary forms of proprietary threat feeds:

- Behavioral threat research is a narrative commentary describing examples of attacks, tactics, techniques, and procedures (TTPs) gathered through primary research sources.
- Reputational threat intelligence is lists of Internet Protocol (IP) addresses and domains associated with malicious behavior, plus signatures of known file-based malware.
- Threat data is computer data that correlates events observed on a customer's networks and logs with known TTPs, and threat actor indicators.

The following are NOT included as primary forms of proprietary threat feeds:

- Vulnerability management is a cornerstone of modern cybersecurity practices aimed at identifying, classifying, remediating, and mitigating vulnerabilities within a system or network.
- The dark net and the dark web are deep web areas that are deliberately concealed from "regular" browser access.
- Bug bounties are related to bug bounty programs that open the testing process to a global community of independent security researchers.

q_vuln_assess_third-party_threat_feed_secp8

As the new chief information security officer (CISO) for a mid-sized company, you are tasked with enhancing the organization's vulnerability management practices.

You have a limited budget but need to ensure that your organization stays ahead of the latest threats.

Which type of threat feed would be the MOST effective choice for your situation?

Answers:

- Open-source intelligence
- Information-sharing organization
- ***Third-party threat feeds**
- Internal threat feeds

Explanation:

Third-party threat feeds is the correct answer. Third-party threat feeds, both open-source and proprietary, provide real-time information on the latest cyber threats and vulnerabilities. They aggregate data from various sources and can be integrated into an organization's security infrastructure. This makes them a cost-effective solution for a mid-sized company with a limited budget, as they provide comprehensive coverage and advanced analytic insights.

While open-source intelligence (OSINT) can provide valuable information about potential threats and vulnerabilities, it requires significant time and resources to collect, analyze, and apply this information effectively. It might not be the most efficient choice for a mid-sized company with a limited budget.

Information-sharing organizations can provide valuable threat intelligence, but their effectiveness can vary depending on the members' contributions and the organization's resources. They might not provide the real-time, comprehensive coverage that a mid-sized company needs to stay ahead of threats.

While internal threat feeds can provide valuable insights based on the organization's specific experiences, they might not provide the broad coverage necessary to stay ahead of the latest threats. They also require significant resources to maintain and analyze, which might not be feasible for a mid-sized company with a limited budget.

q_vuln_assess_threat_secp8

In your role as a security analyst, you need to stay up to date on the latest threats. You are currently reviewing the latest real-time updates on cyberthreats from across the world.

Which of the following resources are you MOST likely using?

Answers:

- ***Threat feeds**
- Advisories and bulletins
- Intelligence fusion
- Threat hunting

Explanation:

Threat feeds provide real-time updates on cyberthreats across the world. They can provide information such as suspicious domains, known malware, known malicious IP addresses, and more.

Advisories and bulletins are usually updated weekly and provide much more detailed information on the newest threats.

Intelligence fusion is the sharing of information between multiple government agencies and private security firms.

Threat hunting is the human-based, proactive and methodical monitoring of a network, systems, and software. This is done in order to detect any suspicious activity that may have evaded the automated tools.

q_vuln_assess_vuln_01_secp8

You want to be able to identify the services running on a set of servers on your network.

Which tool would BEST give you the information you need?

Answers:

- Port scanner
- Protocol analyzer
- ***Vulnerability scanner**
- Network mapper

Explanation:

Use a vulnerability scanner to gather information about systems such as the applications or services running on a system. A vulnerability scanner often combines functions found in other tools and can perform additional functions, such as identifying open firewall ports, missing patches, and default or blank passwords.

A port scanner is a tool that probes systems for open ports. A port scanner tells you which ports are opened in the firewall, but it cannot identify services running on a server if the firewall port has been closed. A network mapper is a tool that can discover devices on a network and shows those devices in a graphical representation. Network mappers typically use a ping scan to discover devices and a port scanner to identify open ports on those devices.

Use a protocol analyzer to identify traffic that is sent on the network medium and traffic sources. Services could still be running on a server that do not generate network traffic that a protocol analyzer would catch.

q_vuln_assess_vuln_02_secp8

You have run a vulnerability scanning tool and identified several patches that need to be applied to a system.

What should you do next after applying the patches?

Answers:

- ***Run the vulnerability assessment again.**
- Use a port scanner to check for open ports.
- Update the vulnerability scanner definition files.
- Document your actions.

Explanation:

After fixing an identified vulnerability, you should re-run the vulnerability scan to verify that everything has been fixed and that additional issues are not present.

You should update definition files before you run the first scan. Using a port scanner is unnecessary because most vulnerability scanners include a check of open ports. Documenting your actions should occur after you have finished all necessary actions.

q_vuln_analysis_analysis_secp8

A cyber engineer enhances processes and controls surrounding exposures and vulnerabilities to meet all regulatory requirements before a year-end inspection.

Which of the following focuses on key aspects of the organization's cybersecurity strategy, including prioritization, considerations of exposure, and risk tolerance contexts?

Answers:

- ***Vulnerability analysis**
- Open-source intelligence (OSINT)
- Common Vulnerability Scoring System (CVSS)
- Common Vulnerabilities and Exposures (CVE)

Explanation:

Vulnerability analysis is critical in supporting several key aspects of an organization's cybersecurity strategy, including prioritization, vulnerability classification, exposure considerations, organizational impact, and risk tolerance contexts.

Not best suited for this scenario, open-source intelligence describes collecting and analyzing publicly available information and using it to support decision-making.

Additionally, the Common Vulnerability Scoring System (CVSS) is the product of the Forum of Incident Response and Security Teams, and its metrics generate a score from 0 to 10 based on vulnerability characteristics.

Common Vulnerabilities and Exposures (CVE) is a dictionary of vulnerabilities in published operating systems and applications software and provides the principal input for NIST's National Vulnerability Database.

q_vuln_analysis_auditing_secp8

You are a cybersecurity analyst who has recently implemented a remediation plan for a critical vulnerability in your organization's network. Your manager has asked you to ensure the effectiveness of your remediation efforts.

What is the MOST crucial next step you should take?

Answers:

- Inform the stakeholders about the remediation
- Update the organization's vulnerability database
- ***Auditing the remediation process**
- Move on to the next identified vulnerability

Explanation:

Auditing the remediation process is the correct answer. Auditing involves an in-depth examination of the remediation process by reviewing the steps taken to address the vulnerability and ensuring they align with the organization's policies and best practices. Audits verify that necessary documentation has been updated, such as records of identified vulnerabilities, remediation actions taken, and any exceptions or exemptions granted. This step is crucial in validating the effectiveness of the remediation efforts.

While it's important to keep stakeholders informed, it's not the most crucial next step. Before informing stakeholders, you need to ensure that the remediation has been successful and hasn't introduced new vulnerabilities.

While updating the vulnerability database is an important step in the vulnerability management process, it should be done after validating the remediation. If the remediation was not successful or introduced new vulnerabilities, the database would need to be updated accordingly.

Moving on to the next vulnerability without validating the remediation of the current one could leave your organization exposed. If the remediation was not successful or introduced new vulnerabilities, you would not be aware of this without validation.

q_vuln_analysis_exposure_secp8

You are the lead cybersecurity analyst for a multinational corporation. Your team has recently completed a vulnerability analysis of the company's IT infrastructure.

The CEO has requested a briefing on the most critical consideration that should guide the company's remediation efforts.

Which of the following considerations should you emphasize in your briefing?

Answers:

- Prioritization
- Classification
- ***Exposure factor**
- Risk tolerance

Explanation:

Exposure factor is the correct answer. The exposure factor represents the extent to which an asset is susceptible to being compromised or impacted by a specific vulnerability. It considers the accessibility of a vulnerable system or data and environmental factors like the current threat landscape or the specifics of the organization's IT infrastructure. These factors significantly influence the likelihood of a vulnerability being exploited and directly impact its overall risk level. Therefore, understanding the exposure factor is crucial in guiding remediation efforts.

While prioritization is an important aspect of vulnerability analysis, it is not the most critical consideration. Prioritization helps to identify the most critical vulnerabilities based on factors such as severity, ease of exploitation, and potential impact. However, without considering the exposure factor, prioritization might not accurately reflect the actual risk to the organization.

Classification aids in categorizing vulnerabilities based on their characteristics. While it helps to clarify the scope and nature of threats, it does not directly influence the remediation efforts. It is a step in the process, but not the most critical consideration.

Risk tolerance refers to the level of risk an organization is willing to accept. While it is important to align vulnerability analysis with risk tolerance, it is not the most critical consideration. Risk tolerance is more about the organization's overall risk management strategy, while the exposure factor directly influences the immediate remediation efforts.

q_vuln_analysis_prioritization_secp8

A company has added several new assets and software to its system and is meeting to review its risk matrix. It wants to ensure risk management efforts focus on vulnerabilities MOST likely impacting its operations significantly.

What is this commonly referred to as?

Answers:

- ***Prioritization**
- Risk tolerance
- Classification
- Environmental variables

Explanation:

Prioritization of vulnerabilities that affect a company ensures the resolution of the most critical vulnerabilities first. The measure of the impact and exposure of the vulnerabilities determines the rank on prioritization.

Risk tolerance is the level of risk that a company is willing to accept in its daily operations, not the ranking of risks.

Classification categorizes vulnerabilities based on their characteristics, such as the type of system or application affected, the nature of the vulnerability, or the potential impact.

Environmental variables related to vulnerability analysis refer to the systems and software a company has currently in use. Age and diversity, as well as complexity, are all variables.

q_vuln_analysis_reporting_secp8

You are a cybersecurity analyst for a large corporation. Your team has recently completed a vulnerability analysis, and you are tasked with creating a comprehensive vulnerability report.

What is the MOST critical information to include in your report to effectively guide the organization's remediation efforts?

Answers:

- The names of the team members who conducted the vulnerability analysis.
- The software tools used in the vulnerability analysis.
- ***The potential impact of each vulnerability and recommendations for addressing them.**
- The number of vulnerabilities found in each department.

Explanation:

The potential impact of each vulnerability and recommendations for addressing them is the correct answer. This information is crucial for helping the organization understand the severity of each vulnerability and how to address it. Including the potential impact helps the organization prioritize which vulnerabilities to address first, and providing recommendations for addressing each vulnerability gives the organization a clear path forward.

While it's important to acknowledge the work of the team, this information does not directly contribute to the organization's remediation efforts and is therefore not the most critical information to include in the report.

While it's good to document the tools used for transparency and reproducibility, this information is not the most critical for guiding the organization's remediation efforts.

While this information can provide some insights into where vulnerabilities are concentrated, it does not provide enough detail to guide the organization's remediation efforts effectively. It's more important to understand the potential impact of each vulnerability and how to address it.

7.2 Vulnerability Scanning

As you study this section, answer the following questions:

- What is the purpose of vulnerability scanning?
- What information is critical in vulnerability scanning?
- What software is available to complete a vulnerability scan on a network?

In this section, you will learn to:

- Conduct vulnerability scans.
- Scan a network with Nessus.
- Scan a network with OpenVAS.
- Scan for cleartext vulnerabilities.
- Scan for FTP vulnerabilities.
- Scan for TLS vulnerabilities.
- Scan for Windows vulnerabilities.
- Scan for Linux vulnerabilities.
- Scan for domain controller vulnerabilities.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	2.2 Explain common threat vectors and attack surfaces.
	• Vulnerable software
	
	4.3 Explain various activities associated with vulnerability management.
	• Identification methods
	  ○ Vulnerability scan
	  ○ Application security
	  ▪ Static analysis
	  ▪ Dynamic analysis
	  ▪ Package monitoring
	• Analysis
	  ○ Common Vulnerability Enumeration (CVE)
	  ○ Vulnerability classification
	
	4.4 Explain security alerting and monitoring concepts and tools.
	• Monitoring computing resources
	  ○ Systems
	  ○ Applications
	  ○ Infrastructure

	• Activities
	  ○ Scanning
	  ○ Reporting
	• Tools
	  ○ Vulnerability scanners
	
	4.9 Given a scenario, use data sources to support an investigation.
	
	• Data sources
	  ○ Dashboards

TestOut Security Pro	5.2 Assessment techniques 5.2.3 Scan for vulnerabilities

7.2.1 Vulnerability Scanning (Lesson Video)

Transcript:

A vulnerability scan is a security assessment technique used to identify and evaluate potential weaknesses or vulnerabilities in a computer system, network, or application. It involves scanning the target system for known vulnerabilities, misconfigurations, or security loopholes that could be exploited by attackers. Vulnerability scans are performed internally and externally to inventory vulnerabilities from different network viewpoints. Vulnerabilities identified during scanning are then classified and prioritized for remediation by security operations teams.

A network vulnerability scanner, such as Tenable Nessus or OpenVAS, is designed to test network hosts, including client PCs, mobile devices, servers, routers, and switches. It performs three primary functions: discovery, assessment, and prioritization. During discovery, it examines an organization's on-premises systems, applications, and devices. It then assesses the scan results, comparing them to configuration templates and lists of known vulnerabilities.
Typical results from a vulnerability assessment will identify missing patches, deviations from baseline configuration templates, and other related vulnerabilities. The tool compiles a report about each vulnerability. Each identified vulnerability is categorized and prioritized using an assigned impact warning. Most tools also suggest remediation techniques. This information is highly sensitive, so using these tools and distributing the reports produced should be restricted to authorized hosts and user accounts.
Credentialed and non-credentialed scans are two different approaches to conducting vulnerability scans.
A credentialed scan, also known as an authenticated scan, requires the scanning tool to provide valid credentials to access the target system. This allows the scan to gather more comprehensive information about the system's configuration, installed software, and other details that may not be accessible without proper authentication.
In contrast, non-credentialed scans, also known as unauthenticated scans, don't require credentials to access the target system. Instead, it relies on external scanning techniques to probe for vulnerabilities and potential security issues.
Both types of scans have their own advantages and limitations. Credentialed scans offer a more accurate assessment of vulnerabilities but require privileged access to the target system. On the other hand, non-credentialed scans can be performed remotely and quickly, making them suitable for high-level assessments or initial security checks. However, they generally provide a less detailed view of the system's security posture compared to the credentialed scans.
Similarly, application vulnerability scanning describes a specialized method for identifying software application weaknesses. This includes static analysis and dynamic analysis. Static analysis involves reviewing application code without executing it. It involves examining the code for potential vulnerabilities, bugs, coding standards violations, and other issues that could impact the security, performance, or maintainability of the software.
Dynamic analysis involves executing a program and observing its behavior in real-time. It also tests running applications that can identify issues like unvalidated inputs, broken access controls, and SQL injection vulnerabilities.
Another critical capability in application vulnerability assessment practices includes package monitoring. Package monitoring is the practice of tracking and monitoring software packages or dependencies used in an application. It

involves keeping a close watch on the versions, vulnerabilities, and updates of these packages to ensure the security and integrity of the application.
Modern applications often rely on third-party libraries, frameworks, or modules that provide pre-built functionalities. These packages can introduce vulnerabilities if they contain outdated or insecure components. Package monitoring helps identify such vulnerabilities and allows developers to take appropriate actions to mitigate potential risks.
That's it for this lesson. In this lesson, we discussed vulnerability scanning. We looked at the three stages of network vulnerability scanning. We also looked at credentialed and non-credentialed scans. We talked about application vulnerability scanning and package monitoring—methods used to enhance the overall security posture of an organization's software.

7.2.2 Conduct Vulnerability Scans (Demo Video)

Transcript:

Throughout this course, we talk about many scanning methods. Typically, you scan for a specific purpose, often to look for vulnerabilities. Vulnerability scanning attempts to find points that can be exploited on a computer or network.

A vulnerability scan can detect and sometimes classify system weaknesses in computers, networks, and other equipment. The scan can also predict the effectiveness of countermeasures that you might implement. A scan may be performed by an IT department or someone hired to perform a penetration test. There are several good tools that perform vulnerability scanning. But if you're on a budget, you can use nmap with a script, the Nmap Scripting Engine, to do a vulnerability scan.
I'm on a Kali Linux system. This system comes with a whole bunch of scripts, but the one we want isn't included. That's not a problem; we can go out to the web and find it. To get the script, we'll go to Github.
I've already located the web page with the script. This is the one that we want. I'll open that link. Down here, in the description, it says that the script uses some well-known service to provide information about vulnerabilities. That's really not a great description, but I happen to know that it works pretty well.
To get the script, you need to click on this Clone or Download link and copy the address. Now, we'll open the terminal, type in 'git clone', paste in the rest of the address, and press Enter on the keyboard. I've already done that, so I won't do it again.
When I was doing this, I wasn't paying attention, and it went into the root directory, so I had to go in and move it to the /usr/share/nmap/scripts directory so nmap knows where to find it by default. If you have some basic Linux skills, it shouldn't be a problem to move to the directory before downloading the script.
All right. On my network, I have a Windows 10 system, and I've installed XAMPP on it with some web pages, php, forms, and so on. I want to put it out there facing the public internet. But I'm not sure if it has any vulnerabilities. This is my example. I could also have other systems that I can scan. But for this demo, I'm just going to scan this particular system. Since I'm familiar with this system, I already know the IP address. To begin, I want to just do a regular service scan with nmap to see what we get. For that, I'll type in 'nmap -sV 10.10.10.195' and press Enter. It takes a few seconds to get the results. When it's done, you can see that I have a few open ports and services running. As I already mentioned, this system is running a web server, Apache, along with other services, so I'm concerned about it. Now let's run this scan with the script.
To run the script, we'll type 'nmap - -script nmap-vulners -sV 10.10.10.195' and press Enter. This will take a few seconds. The scan is done. Now we have some additional information. Right here, we have some information under Apache and port 443. I'm going to hold down the Ctrl key and click on this hyperlink. It'll open Firefox, and I'll go to the page where I can read more about this particular vulnerability. I'll scroll down. Under the description, it tells me exactly what this issue is. It looks like someone could execute some code, so it's probably not something I want to let loose on the web until I do more research and fix any problems.
While we're in Firefox, let's jump back over to the Github tab. I'll go back a page. There are other scripts here that do some additional scans. If you have a test environment (and you should), you can download others and see what type of results you can get. Remember that you can run multiple scripts in one scan.
That's it for this demo. In this demo, we used nmap and the Nmap Scripting Engine to do a vulnerability scan on a Windows 10 system running XAMPP. First, we went to Github to locate the scripts we needed. Then we did a regular service scan with nmap. We did another scan using the script, and then we used the web to learn more about one of the vulnerabilities that the script found.

7.2.3 Scanning a Network with Nessus (Demo Video)

Transcript:

In this demonstration, we're going to work with the Nessus Vulnerability Scanner. Nessus is a very powerful security tool that you can use to scan for security vulnerabilities on your network.

Nessus is accessed via a web page on port 8834. I've installed Nessus on this machine, so I'm just connecting to localhost. For this demo, I'm running an evaluation copy of Nessus, but that's sufficient to show what it can do.
Let's start by logging in. After I log in, we see the home page. Here, we can see the various scans that have already been created. There are many different features and options in Nessus, but for this demo, I'll stick to showing how to create and run a network scan.
While I could create a custom scan profile, Nessus includes quite a few useful templates that can accomplish most of what I typically need. To create a scan, I'll start by selecting New Scan from the top right. Here, we can see some of the templates I mentioned. I'm going to run a basic network scan, so I'll select that template. This template scans a specified host or network range for known vulnerabilities.
To set up the scan, I'll need to provide a name for it, as well as a network address that I'd like to scan. I'm going to name this 'home gateway scan' since I'll be scanning the computers at my house with it. My gateway is located at 10.0.0.1, so that's what I'll supply as the target. There are many other options that I could configure, including port discovery and authenticated scanning, but I just want to do a simple scan today. Since everything I need is configured, I'll click Save.
Now that I've returned to the home page, I can see that the new scan has been created, but isn't running yet. I can click Launch to start it.
The scan's title changes to bold, and a spinning green icon appears to show that the scan is active. I can watch the scan live by clicking on it. This screen shows information about the different hosts that are discovered and the vulnerabilities that are found. Nessus also keeps a historical log of all the times a scan has been run so that I can compare how vulnerabilities have improved on my network over time.
This scan is going to take a while, so I'll pause the demo until it's finished.
Now that the scan has finished, we can see that my gateway has quite a few vulnerabilities. Luckily, most of them are labelled as informational. This means that the tool found information that could be useful for a security administrator to know about a host, but that the information doesn't immediately indicate a problem. An example of the type of data that would be labelled as informational is a list of open network ports. Network ports have to be open on some machines for them to function properly, but opening unexpected ports can cause problems.
More serious vulnerabilities are color-coded from green to red. Low-severity vulnerabilities aren't as interesting as high or critical vulnerabilities, so I'll take a look at one of the worst issues Nessus found.
When I select a vulnerability, it shows me information about the issue. In many cases, software creators patch high and critical vulnerabilities, and a relevant CVE entry is listed. Nessus provide a description and a suggested solution for many issues, as well as relevant information related to the vulnerability.
And that's it for this demo. We discussed how to conduct a vulnerability scan with Nessus. We looked at what Nessus is and what it does. And we ran a vulnerability scan on my home network and explored the results.

7.2.4 Scanning a Network with OpenVAS (Demo Video)

Transcript:

Greenbone's OpenVAS is a powerful network security scanner equipped with various tools, including an intuitive graphical user interface. At its core, OpenVAS comprises a server packed with a suite of network vulnerability tests designed to identify security issues within remote systems and applications. This versatile tool serves offensive and defensive security professionals, enabling them to assess and uncover potential attack surfaces. In this demonstration, we'll continue to use the traditional name OpenVAS when referring to the scanner.

Before diving into this demonstration, I downloaded OpenVAS as a virtual appliance and imported it into a hypervisor, setting it up as a virtual machine. The system is configured, and I've run some tests, so we're ready to proceed. I'm at the login screen and will use the credentials created during the setup phase.

After logging in, I'm directed to the Dashboard screen. This provides a quick overview of previous scans and their status. It's important to note that security scanners, like antivirus software, rely on up-to-date definitions. Let's examine this briefly.
I'll navigate to the Administration tab and click on Feed Status. This column shows that all our feeds are up to date. I'm particularly interested in the CVEs (Common Vulnerabilities and Exposures).
Now, let's return to the Dashboards. Please remember that this is a test system, and the abundance of red indicates severe issues. In a typical network, such extensive red flags would be highly unusual and cause serious concern. Now, let's explore the Scans menu.
Clicking on Tasks reveals a list of all the tasks I've created. For instance, the "Scan All" task scans my entire subnet. In the Reports section, you'll see that I've run this task three times, each resulting in a report. You can also check the last time the task ran and its severity level. If I wish to run the task, I can start by clicking the appropriate arrow icon. Additional actions include deleting, editing, cloning, or exporting the task.
Now, let's create a new task. There are a couple of ways to do this. We can use the Task Wizard to quickly create a task with default settings, requiring only the entry of the IP address or hostname, whether a single target or an entire range of devices. Another approach is to click on New Task.
I'll name the task Scan All since it's intended for scanning the entire network. Under Scan Targets, we specify what we want to scan. I've created a new target by clicking here.
This opens the New Target configuration window. I'll name it Scan All and enter the network address and subnet I want to scan. Here, you can also specify exclusions if there are devices on your network you wish to skip. Credentials can be provided for a more comprehensive scan.
After clicking Save, we return to the New Task window. You'll see that the Scan All target is already selected. For this task, we'll leave the rest of the settings at their default values and click Save.
Now, looking at the list of tasks, you can find the Scan All task. Since it's new, there have yet to be any reports. While I'm ready to run this task, I want to explore other menu items first.
Under the Scans menu, you'll find options like Reports, Results, Vulnerabilities, and more. Reports display a list of accumulated reports since installing OpenVAS, while Results reveal vulnerabilities discovered during scans. For example, you can identify an operating system that has reached its end of life and the affected host system. Addressing these vulnerabilities is crucial, as outdated systems are unlikely to receive automatic patches.
Returning to the Scans menu, we'll examine the Tasks. On the first page of the list, I'll select a specific report, focusing on a task that scanned IP addresses ending with "100," including a vulnerable host called Metasploitable. I'll click on the report and head to the Results tab to view the issues detected by OpenVAS. These issues range from passwordless logins to an end-of-life operating system and a VNC brute force login vulnerability. Expanding on a particular point provides detailed information and suggests solutions.
Under the Scan menu, there's an extensive list of menu items, including Assets, Configuration, and more. Assets allow you to view scanned hosts, while Configuration lets you create targets and credentials. Lastly, the Administration and Help sections provide access to administration tasks and helpful resources.
This concludes our demonstration. We explored Greenbone's Open Vulnerability Assessment Scanner, also known simply as OpenVAS.

7.2.5 Vulnerability Scanning Facts

This lesson covers the following topics:

- Vulnerability scanning
- Application vulnerability scanning
- Package monitoring

Vulnerability Scanning

Vulnerability management is a cornerstone of modern cybersecurity practices aimed at identifying, classifying, remediating, and mitigating vulnerabilities within a system or network. A vulnerability scanner looks for weaknesses such as:

- Open ports.
- Active IP addresses.

- Running applications or services.
- Missing critical patches.
- Default user accounts that have not been disabled.
- Default or blank passwords.
- Misconfigurations.
- Missing security controls.

One crucial aspect of vulnerability management is vulnerability scanning, a systematic process of probing a system or network using specialized software tools to detect security weaknesses. Vulnerability scans are performed internally and externally to inventory vulnerabilities from different network viewpoints. Vulnerabilities identified during scanning are then classified and prioritized for remediation by security operations teams.

Vulnerability scanning also supports application security, as it helps to locate and identify misconfigurations and missing patches in software. Advanced vulnerability scanning techniques focused on application security include specialized application scanners, pen-testing frameworks, and static and dynamic code testing.

Vulnerability scanning tools like openVAS and Nessus offer a broad range of features to analyze network equipment, operating systems, databases, patch compliance, configuration, etc. While these tools are very effective, application security analysis warrants more specialized approaches. Several specialized tools exist to more deeply analyze how applications are designed to operate and can locate vulnerabilities not typically identified using generalized scanning approaches.

There are different options when running a vulnerability scan. The table below explains each of these options:

Vulnerability Scan Option	Description
Intrusive	An intrusive scan finds a potential vulnerability and then actively attempts to exploit it. This leads to more accurate results but cannot be done on a live system.
Non-intrusive	A non-intrusive scan is the more common type of scan performed. This method scans the network and lists all potential vulnerabilities but cannot validate if the system is vulnerable. This type of scan can be performed on live systems and requires the network defender to take additional actions.
Credentialed	A credentialed scan is given a user account with login rights to various hosts, plus whatever other permissions are appropriate for the testing routines. This sort of test allows much more in-depth analysis, especially in detecting when applications or security settings may be misconfigured. It shows what an insider attack, or an attack with a compromised user account, may achieve. A credentialed scan is a more intrusive type of scan than a non-credentialed scanning.
Non-credentialed	A non-credentialed scan proceeds by directing test packets at a host without being logged on to the OS or application. The view is the one the host exposes to an unprivileged user on the network. The test routines may be able to include things such as using default passwords for service accounts and device management interfaces, but they are not given privileged access. While you may discover more weaknesses with a credentialed scan, you will sometimes want to narrow your focus to that of an attacker who does not have specific high-level permissions or total administrative access. Non-credentialed scanning is the most appropriate technique for external assessment of the network perimeter or when performing web application scanning.

Application Vulnerability Scanning

Similarly, application vulnerability scanning describes a specialized method for identifying software application weaknesses. This includes static analysis (reviewing application code without executing it) and dynamic analysis (testing running

applications), which can identify issues like unvalidated inputs, broken access controls, and SQL injection vulnerabilities. Application vulnerability scanning is typically handled separately from general vulnerability scanning due to the unique nature of software applications and the specific types of vulnerabilities they introduce.

General vulnerability scanning is designed to detect system-wide or network-wide weaknesses, such as out-of-date software or misconfigured firewalls. In contrast, application vulnerability scanning evaluates the coding and behavior of individual software applications. It looks for issues like cross-site scripting (XSS), SQL injection, and insecure direct object references unique to software applications. These application-specific vulnerabilities require specialized tools and techniques to identify and mitigate and are generally different from those used in general vulnerability scanning. Applications frequently have their own release and update cycles, separate from the rest of the environment, necessitating a more targeted vulnerability management process.

Package Monitoring

Another critical capability in application vulnerability assessment practices includes package monitoring. Package monitoring is associated with vulnerability identification because it tracks and assesses the security of third-party software packages, libraries, and dependencies used within an organization to ensure that they are up-to-date and free from known vulnerabilities that malicious actors could exploit. Package monitoring is associated with managing software bill of materials (SBOM) and software supply chain risk management practices.

In an enterprise setting, package monitoring is typically achieved through automated tools and governance policies. Automated software composition analysis (SCA) tools track and monitor the software packages, libraries, and dependencies used in an organization's codebase. These tools can automatically identify outdated packages or packages with known vulnerabilities and suggest updates or replacements. They work by continuously comparing the organization's software inventory against various databases of known vulnerabilities, such as the National Vulnerability Database (NVD) or vendor-specific advisories.

In addition to these tools, organizations often implement governance policies around software usage. These policies may require regular audits of software packages, approval processes for adding new packages or libraries, and procedures for updating or patching software when vulnerabilities are identified.

7.2.6 Scan for Cleartext Vulnerabilities (Simulation)

Scenario

One of the content developers on the Engineering team uses an Embedthis GoAhead webserver for several devices that are maintained by their team.

In this lab, you need to scan the test machine where the Engineering team prepares deployments and complete the following tasks:

- Login to the CompTIA Vulnerability Scanner in Chrome.
  - URL: **http://192.168.0.52**
  - Username: **securityadmin**
  - Password: **P@ssw0rd**
- Use the CompTIA Vulnerability Scanner to scan the test machine found at 192.168.0.45.
- Answer the questions about any vulnerabilities found.

Explanation

Complete this lab as follows:

1. Access the CompTIA Vulnerability Scanner.
    a. URL: http://192.168.0.52
    b. Username: securityadmin
    c. Password: P@ssw0rd (with a zero, not the letter o)
    d. Click **Sign In** .
2. Scan the host at 192.168.0.45.
    a. Click on the **Targets** tab.
    b. Click on **Add Target** .
    c. Name the target **Webserver** or a name of your choice.
    d. In the **Hosts** field, enter **192.168.0.45** , then select **OK** .
    e. Click on the **Tasks** tab.
    f. Click on **Add Task** .
    g. Enter **Scan Webserver** (or a name of your choice) for the **Name** .
    h. Select **Webserver** (or the name you chose) from the **Add Target** list box. Click **OK**
    i. Click the **Run** button to the right to start the scan.
3. View the Vulnerability Scanner report.
    a. Click the **Reports** tab.
    b. Review the contents of the report under **Webserver** (or the name you chose) and answer the questions by clicking the **Answer Questions** button at the top right.
    c. Click **Score Lab** .

7.2.7 Scan for FTP Vulnerabilities (Simulation)

Scenario

A server is used to transfer company financial data to remote branches using the FTP protocol. Since the data is sensitive to the company, you have been asked to scan the host for vulnerabilities.

In this lab, your task is to complete the following:

- Login to the CompTIA Vulnerability Scanner in Chrome.
    - URL: **http://192.168.0.52**
    - Username: **securityadmin**
    - Password: **P@ssw0rd**
- Using the CompTIA Vulnerability Scanner, scan the server found at 192.168.0.46.
- Answer the questions presented about what the Vulnerability Scanner finds.

Explanation

Complete this lab as follows:

1. Access the CompTIA Vulnerability Scanner.
    a. URL: http://192.168.0.52
    b. Username: securityadmin
    c. Password: P@ssw0rd (with a zero, not the letter o)
    d. Click **Sign In** .
2. Scan the host at 192.168.0.46.
    a. Click on the **Targets** tab.
    b. Click on **Add Target** .
    c. Name the target **FTP** or a name of your choice.
    d. In the **Hosts** field, enter **192.168.0.46** , then select **OK** .
    e. Click on the **Tasks** tab.
    f. Click on **Add Task** .
    g. Enter **FTP scan** (or a name of your choice) for the **Name** .

h. Select **FTP** (or the name you chose) from the **Add Target** list box. Click **OK**
i. Click the **Run** button to the right to start the scan.

3. View the Vulnerability Scanner report.
    a. Click the **Reports** tab.
    b. Review the contents of the report under **FTP** (or the name you chose) and answer the questions by clicking the **Answer Questions** button at the top right.
    c. Click **Score Lab** .

7.2.8 Scan for TLS Vulnerabilities (Simulation)

Scenario

An older server has been providing file sharing for Windows, Linux, and MacOS clients to the Sales team.

In this lab, you need to scan the file server to ensure it is secure by completing the following tasks:

- Login to the CompTIA Vulnerability Scanner in Chrome.
    - URL: **http://192.168.0.52**
    - Username: **securityadmin**
    - Password: **P@ssw0rd**
- Use the CompTIA Vulnerability Scanner to scan the test machine found at 192.168.0.46.
- Answer the questions about any vulnerabilities found.

Explanation

Complete this lab as follows:

1. Access the CompTIA Vulnerability Scanner.
    a. URL: http://192.168.0.52
    b. Username: securityadmin
    c. Password: P@ssw0rd (with a zero, not the letter o)
    d. Click **Sign In** .
2. Scan the host at 192.168.0.46.
    a. Click on the **Targets** tab.
    b. Click on **Add Target** .
    c. Name the target **File Server** or a name of your choice.
    d. In the **Hosts** field, enter **192.168.0.46** , then select **OK** .
    e. Click on the **Tasks** tab.
    f. Click on **Add Task** .
    g. Enter **File Server** (or the name you chose) for the **Name** .
    h. Select **File Server** (or the name you chose) from the **Add Target** list box. Click **OK**
    i. Click the **Run** button to the right to start the scan.
3. View the Vulnerability Scanner report.
    a. Click the **Reports** tab.
    b. Review the contents of the report under **File Server** (or the name you chose) and answer the questions by clicking the **Answer Questions** button at the top right.
    c. Click **Score Lab** .

7.2.9 Scan for Windows Vulnerabilities (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You are performing vulnerability scans on your network. Mary is the primary administrator for the network and the only person authorized to perform local administrative actions. The company network security policy requires complex passwords for all users. It is also required that Windows Firewall is enabled on all workstations. Sharing personal files is not allowed.

In this lab, your task is to:

- Login to the CompTIA Vulnerability Scanner in Chrome.
  - URL: http://192.168.0.52
  - Username: securityadmin
  - Password: P@ssw0rd
  - Select **Sign In**
- Create a target for the Office2 workstation (192.168.0.34).
- Create a task and run a vulnerability scan for the Office2 workstation.
- View the report for the scan task you created.
- Remediate the vulnerabilities found in the report for Office2. Use Computer Management, Settings, and File Explorer to make needed changes.
- Re-run a vulnerability scan to make sure all of the issues are resolved.

Explanation

Complete this lab as follows.

1. Login to the CompTIA Vulnerability Scanner on ITAdmin in Chrome.
   - URL: http://192.168.0.52
   - Username: securityadmin
   - Password: P@ssw0rd
   - Select **Sign In**
2. Create a Target for Office2 (192.168.0.34)
   a. Select **Targets** , and then **Add Target** .
   b. Name: Office2 (or a name of your choice)
   c. Hosts: 192.168.0.34
   d. Select **OK**
3. Create a Task to scan the Office2 target and run the task
   a. Select **Tasks** , and then **Add Task** .
   b. Name: **Scan Office2** (or a name of your choice)
   c. To the right of Add Target, select **Office2** (or whatever name you chose)
   d. Select **OK** .
   e. Select **Run** .
4. View the Report for the Task
   a. Select Reports and view the report for Office2 (or whatever name you chose).
   b. Review the results to determine which issues you need to resolve on Office2.
5. Access local users using Office2's Computer Management console.
   a. From the top left, select **Floor 1** .
   b. Under Office 2, select **Office2** .
   c. From Office2, right-click **Start** and select **Computer Management** .
   d. Expand and select **Local Users and Groups** > **Users** .
6. Rename the Administrator user account.
   a. Right-click **Administrator** and select **Rename** .
   b. Enter a ***new name*** of your choice and press **Enter** .
7. Disable the Guest account.
   a. Right-click **Guest** and select **Properties** .
   b. Select **Account is disabled** , and then select **OK** .
8. Set a new password for Mary.
   a. Right-click **Mary** and select **Set Password** .

b. Select **Proceed** .
c. Enter a new **password** of your choice (12 characters or more).
d. Confirm the new **password** , and then select **OK** .
e. Select **OK** .

Ideally, you would create a policy that requires passwords with 12 characters or more with special characters and mixed cases.

9. Configure Mary's password to expire and to change at next logon.
    a. Right-click **Mary** and select **Properties** .
    b. Clear **Password never expires** .
    c. Select **User must change password at next logon** , and then select **OK** .
10. Unlock Susan's account and remove her from the Administrators group.
    a. Right-click **Susan** and select **Properties** .
    b. Clear **Account is locked out** , and then select **Apply** .
    c. Select the **Member of** tab.
    d. Select **Administrators** .
    e. Select **Remove** .
    f. Select **OK** .
    g. Close Computer Management.
11. Enable Windows Firewall for all profiles.
    a. Right-click **Start** , and then select **Settings** .
    b. Select **Network & Internet** .
    c. From the right pane, scroll down and select **Windows Firewall** .
    d. Under Domain network, select **Turn on** .
    e. Under Private network, select **Turn on** .
    f. Under Public network, select **Turn on** .
    g. Close all open Windows.
12. Remove a file share.
    a. From the taskbar, select **File Explorer** .
    b. From the left pane, select **This PC** .
    c. From the right pane, double-click **Local Disk (C:)** .
    d. Right-click **MyMusic** and select **Properties** .
    e. Select the **Sharing** tab.
    f. Select **Advanced Sharing** .
    g. Clear **Share this folder** .
    h. Select **OK** .
    i. Select **Close** .
13. Use the CompTIA Vulnerability Scanner from ITAdmin to verify that all of the issues on the Office2 computer were resolved.
    a. From the top left, select **Floor 1** .
    b. Under IT Administration, select **ITAdmin** .
    c. In the CompTIA Vulnerability Scanner, under Tasks, select **Rerun** .
    d. Select Reports and view the report for Office2 (or whatever name you chose)
    e. Review the results to determine if you need to resolve additional issues on Office2.

7.2.10 Scan for Linux Vulnerabilities (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You need to use a vulnerability scanner to check for security issues on your Linux computers.

In this lab, your task is to:

- Login to the CompTIA Vulnerability Scanner in Chrome.
    - URL: **http://192.168.0.52**
    - Username: **securityadmin**
    - Password: **P@ssw0rd**
- Create a target for the Linux computers on IP range **192.168.0.60 - 192.168.0.69**
- Answer the first question
- Create a task and run a vulnerability scan for the Linux range.
- View the report for the scan task you created.
- Answer the remaining questions.

Explanation

Complete this lab as follows:

1. Login to the CompTIA Vulnerability Scanner on ITAdmin in Chrome.
    - URL: **http://192.168.0.52**
    - Username: **securityadmin**
    - Password: **P@ssw0rd**
    - Select **Sign In**
2. Create a Target for theIP address range of 192.168.0.60 through 192.168.0.69.
    a. Select **Targets** , and then **Add Target** .
    b. Enter a Name of your choice.
    c. For Hosts, enter **192.168.0.60 - 192.168.0.69**
    d. Select **OK** .
    e. Expand the target you created to view the detected hosts.
    f. Answer Question 1.
3. Create a Task to scan the Linux range target and run the task
    a. Select **Tasks** , and then **Add Task** .
    b. Enter a Name of your choice
    c. To the right of Add Target, select your target.
    d. Select **OK** .
    e. Select **Run** .
4. View the Report for the Task
    a. Select Reports and view the report for your scan task
    b. Review the results and then answer Questions 2 through 5.

7.2.11 Scan for Domain Controller Vulnerabilities (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You are performing vulnerability scans on your network. Use the CompTIA Vulnerability Scanner tool to run a vulnerability scan on the CorpDC domain controller.

In this lab, your task is to:

- Login to the CompTIA Vulnerability Scanner in Chrome.
    - URL: http://192.168.0.52
    - Username: securityadmin
    - Password: P@ssw0rd
- Create a target for the CorpDC server (192.168.0.11).
- Create a task and run a vulnerability scan for the CorpDC server.
- View the report for the scan task you created.
- Remediate the vulnerabilities in the Default Domain Policy using Group Policy Management on CorpDC.

- Re-run a vulnerability scan to make sure all of the issues are resolved.

Explanation

While completing this lab, use the following information:

Area	Policy	Setting
Password Policy	Enforce password history	**24 Passwords**
	Minimum password age	**1 Day**
	Minimum password length	**14 Characters**
Account Lockout Policy	Reset account lockout counter after	**60 Minutes**
Event Log	Retention method for application log	**Do not overwrite events (clear log manually)**
	Retention method for security log	**Do not overwrite events (clear log manually)**
	Retention method for system log	**Do not overwrite events (clear log manually)**
System Services	DCOM Server Process Launcher	**Disabled**
	Task Scheduler	**Disabled**

Complete this lab as follows:

1. Login to the CompTIA Vulnerability Scanner on ITAdmin in Chrome.
   - URL: http://192.168.0.52
   - Username: securityadmin
   - Password: P@ssw0rd
2. Create a Target for CorpDC (192.168.0.11)
   a. Select **Targets** , and then **Add Target** .
   b. Name: **CorpDC** (or a name of your choice)
   c. Hosts: **192.168.0.11**
   d. Select **OK**
3. Create a Task to scan the CorpDC (or the name you chose) target and run the task
   a. Select **Tasks** , and then **Add Task** .
   b. Name: **Scan CorpDC** (or a name of your choice)
   c. Next to Add Target, select **CorpDC** (or the name you chose)
   d. Select **OK** .
   e. Select **Run** .
4. View the Report for the Task
   a. Select Reports and view the report for CorpDC (or the name you chose)
   b. Review the results to determine which issues you need to resolve on CorpDC.

5. Access the CorpDC server.
    a. From the top left, select **Floor 1** .
    b. Under Networking Closet, select **CorpDC** .

    If you need to return to the ITAdmin computer to review the report:

    1. From the top left, select **Floor 1** .
    2. Under IT Administration , select **ITAdmin** .

6. Access and edit the **CorpNet.local Default Domain Policy** .
    a. From Server Manager, select **Tools** > **Group Policy Management** .
    b. Maximize the window for better viewing.
    c. Expand **Forest: CorpNet.local** > **Domains** > **CorpNet.local** .
    d. Right-click **Default Domain Policy** and then select **Edit** .
    e. Maximize the window for better viewing.
7. Remediate the password policy issues in **Account Policies** .
    a. Under Computer Configuration, expand **Policies** > **Windows Settings** > **Security Settings** > **Account Policies** .
    b. From the left pane, select **Password Policy** .
    c. From the right pane, double-click the ***policy*** .
    d. Select **Define this policy setting** .
    e. Enter the ***password setting*** and then select **OK** .
    f. Repeat steps 7c-7e for each additional password policy.
8. Remediate the reset account lockout counter issue in **Account Policies** .
    a. From the left pane, select **Account Lockout Policy** .
    b. From the right pane, double-click **Reset account lockout counter after** .
    c. Select **Define this policy setting** .
    d. Enter **60** minutes and then select **OK** .
9. Remediate the Event Log issues.
    a. From the left pane, select **Event Log** .
    b. From the right pane, double-click the ***policy*** .
    c. Select **Define this policy setting** .
    d. Select **Do not overwrite events (clear log manually)** and then select **OK** .
    e. Repeat steps 9b–9d for each additional Event Log policy.
10. Remediate System Services issues.
    a. From the left pane, select **System Services** .
    b. From the right pane, double-click the ***policy*** .
    c. Select **Define this policy setting** .
    d. Make sure **Disabled** is selected, and then select **OK** .
    e. Repeat steps 10b-10d for the remaining System Services policy.
11. Use the CompTIA Vulnerability Scanner from ITAdmin to verify that all the issues on the CorpDC server were resolved.
    a. From the top left, select **Floor 1** .
    b. Under IT Administration, select **ITAdmin** .
    c. In the CompTIA Vulnerability Scanner, under Tasks, select **Rerun** .
    d. Select **Reports** and view the report for CorpDC.
    e. Review the results to determine if you need to resolve additional issues on CorpDC.

7.2.12 Practice Questions (Section Quiz)

q_vuln_scanning_credentialed_01_secp8

Which of the following are key purposes of running a credentialed scan in a vulnerability assessment? (Select two.)

Answers:

- ***Testing routines**
- Public network access
- ***Compromised user account**
- External network perimeter
- Unprivileged user access

Explanation:

The following answers are correct:

- Testing routines are a key aspect of a credentialed scan. The scan is given a user account with login rights to various hosts, plus whatever other permissions are appropriate for the testing routines. This allows for a more in-depth analysis of the system.
- A credentialed scan simulates what an insider attack, or an attack with a compromised user account, may achieve. This is because it is given the same level of access as these potential threats.

Public network access is not a key aspect of a credentialed scan. Credentialed scans are typically performed internally and do not require public network access.

The external network perimeter is not a key aspect of a credentialed scan. While the external network perimeter may be scanned during a vulnerability assessment, this is typically done using non-credentialed scans.

Unprivileged user access is not a key aspect of a credentialed scan. Credentialed scans are given privileged access to the system to allow for a more thorough analysis.

q_vuln_scanning_credentialed_02_secp8

You are a cybersecurity analyst at a large corporation. Your team has been tasked with conducting a vulnerability assessment of the company's internal network. You have been given the option to perform either a credentialed or non-credentialed scan.

Which of the following factors would most strongly suggest that a credentialed scan is the appropriate choice for this situation?

Answers:

- The company's network has recently been targeted by a series of external cyber attacks.
- The company has a large number of third-party applications installed on its network.
- ***The company has recently implemented a new security policy that restricts the use of administrative privileges.**
- The company's IT department has recently installed a new patch management system.

Explanation:

A credentialed scan is designed to provide a more in-depth analysis of the network, including detecting misconfigurations in security settings. If the company has recently implemented a new security policy that restricts the use of administrative privileges, a credentialed scan would be able to assess the impact of this policy and identify any potential vulnerabilities that may have been introduced.

While external cyber attacks are a serious concern, they are not the primary reason to choose a credentialed scan. A non-credentialed scan would be more appropriate for assessing the vulnerabilities visible to an external attacker.

While third-party applications can introduce vulnerabilities, a credentialed scan is not specifically designed to assess these. Application vulnerability scanning would be more appropriate for this purpose.

While a new patch management system could potentially introduce vulnerabilities, a credentialed scan is not specifically designed to assess these. A patch management audit would be more appropriate for this purpose.

q_vuln_scanning_dynamic_analysis_secp8

An application security analyst at a software company is assessing a new software application before releasing it to customers. Before deciding on the BEST approach for the assessment, the analyst recalls that there are different methods of analysis to evaluate the software's security posture.

The analyst wants to assess the software's running state to identify potential vulnerabilities during its execution.

Considering the preference to evaluate the software in its running state and identifying vulnerabilities during execution, which type of examination should the analyst primarily rely on?

Answers:

- Static code review
- Manual penetration testing
- ***Dynamic analysis**
- Source code fingerprinting

Explanation:

Dynamic analysis evaluates the software application in its running state and looks for vulnerabilities during its execution, which aligns with the analyst's requirement in the scenario.

Static code review evaluates the software's source code, bytecode, or application binaries without executing the software. While it is a valuable method, static code review does not meet the analyst's preference to assess the software while running.

Manual penetration testing involves actively probing for vulnerabilities in a running application, but is broader than just analyzing the software's execution and can involve various techniques not limited to the software's runtime behavior.

Source code fingerprinting involves snippets within files that match content in source files found in third-party components. Source code fingerprints act as identifiers of likely third-party content within the scanned file. While a valid approach, it is not the best approach for this scenario.

q_vuln_scanning_noncredentialed_01_secp8

Which of the following are key areas of focus for a non-credentialed scan in a vulnerability assessment? (Select two.)

Answers:

- ***External network perimeter**
- Privileged user access
- ***Unprivileged user access**
- Internal network access
- Compromised user account

Explanation:

The following answers are correct:

- The external network perimeter is a key focus of a non-credentialed scan. Non-credentialed scans are often used to assess the security of the network perimeter from an external viewpoint, simulating the perspective of an attacker who does not have specific high-level permissions or total administrative access.
- Unprivileged user access is a key focus of a non-credentialed scan. Non-credentialed scans simulate the view that the host exposes to an unprivileged user on the network.

Privileged user access is not a key focus of a non-credentialed scan. Non-credentialed scans are performed without logging into the system or application, thus they do not have privileged user access.

Internal network access is not a key focus of a non-credentialed scan. While non-credentialed scans can be used internally, they are often used to assess the security of the network perimeter from an external viewpoint.

A compromised user account is not a key focus of a non-credentialed scan. Non-credentialed scans are performed without logging into the system or application, thus they do not simulate an attack from a compromised user account.

q_vuln_scanning_noncredentialed_02_secp8

You are a cybersecurity analyst at a financial institution. Your team has been tasked with conducting a vulnerability assessment of the company's external network perimeter.

You have been given the option to perform either a credentialed or non-credentialed scan.

Which of the following factors would MOST strongly suggest that a non-credentialed scan is the appropriate choice for this situation?

Answers:

- ***The company's network has recently been targeted by a series of external cyber attacks.**
- The company has a large number of third-party applications installed on its network.
- The company has recently implemented a new security policy that restricts the use of administrative privileges.
- The company's IT department has recently installed a new patch management system.

Explanation:

A non-credentialed scan is designed to mimic the perspective of an external attacker who does not have privileged access to the network. If the company's network has recently been targeted by external cyber attacks, a non-credentialed scan would be the most appropriate choice to identify the vulnerabilities that an external attacker could potentially exploit.

While third-party applications can introduce vulnerabilities, a non-credentialed scan is not specifically designed to assess these. Application vulnerability scanning would be more appropriate for this purpose.

A non-credentialed scan does not require administrative privileges and therefore would not be affected by a policy that restricts the use of these privileges. A credentialed scan, which provides a more in-depth analysis of the network, would be more appropriate in this situation.

While a new patch management system could potentially introduce vulnerabilities, a non-credentialed scan is not specifically designed to assess these. A patch management audit would be more appropriate for this purpose.

q_vuln_scanning_nvd_secp8

As a cybersecurity analyst, you are tasked with identifying known vulnerabilities in the third-party software packages, libraries, and dependencies used within your organization.

Which of the following would be the MOST effective tool for accomplishing this task?

Answers:

- Software Bill of Materials (SBOM)
- Software composition analysis (SCA)
- ***National Vulnerability Database (NVD)**
- Intrusion detection system (IDS)

Explanation:

The National Vulnerability Database (NVD) is a U.S. government repository of standards-based vulnerability management data. It includes databases of security checklist references, security-related software flaws, misconfigurations, product names, and impact metrics. It is the most effective tool for identifying known vulnerabilities in third-party software packages, libraries, and dependencies.

A Software Bill of Materials (SBOM) is a comprehensive list of components in a piece of software. It provides detailed information about each component, including its source and version number. While an SBOM is useful for understanding what components are in your software, it does not provide information about known vulnerabilities.

Software composition analysis (SCA) tools are used to identify open source components in code and check them against known vulnerability databases. While SCA is a valuable tool in a cybersecurity toolkit, it does not provide a comprehensive list of known vulnerabilities that exist in third-party software packages, libraries, and dependencies.

An intrusion detection system (IDS) is designed to monitor network traffic for suspicious activity and issue alerts when such activity is detected. While an IDS is an important part of a comprehensive cybersecurity strategy, it is not specifically designed to identify known vulnerabilities in third-party software packages, libraries, and dependencies.

q_vuln_scanning_package_monitoring_secp8

You are a cybersecurity analyst at a large organization. You've noticed that several third-party software packages used within your organization have not been updated in a while.

What is the MOST appropriate action to take?

Answers:

- Ignore the issue as it's not your responsibility to update third-party software.
- Update the software packages immediately without informing anyone
- ***Inform your manager about the issue and suggest implementing automated package monitoring.**
- Delete the outdated software packages from the system.

Explanation:

Informing your manager about the issue and suggesting the implementation of automated package monitoring is the most appropriate action. Package monitoring is associated with vulnerability identification because it tracks and assesses the security of third-party software packages, libraries, and dependencies used within an organization to ensure that they are up-to-date and free from known vulnerabilities.

Ignoring the issue is not the right approach. Outdated software packages can pose a security risk as they might contain known vulnerabilities that malicious actors could exploit.

Updating the software packages immediately without informing anyone is not the right approach. It's important to communicate with your team and follow the proper procedures for updating software.

Deleting the outdated software packages from the system is not the right approach. These packages might be necessary for certain operations within the organization. Instead, they should be updated to the latest version.

q_vuln_scanning_sbom_secp8

As a cybersecurity analyst, you are tasked with improving the security of your organization's software applications. One of your responsibilities is to ensure that all third-party software packages, libraries, and dependencies used within your organization are up-to-date and free from known vulnerabilities.

Which of the following would be the MOST effective tool for accomplishing this task?

Answers:

- Software composition analysis (SCA)
- ***Software Bill of Materials (SBOM)**
- National Vulnerability Database (NVD)
- Intrusion detection system (IDS)

Explanation:

A Software Bill of Materials (SBOM) is a comprehensive list of components in a piece of software. It provides detailed information about each component, including its source, version number, and any known vulnerabilities. This makes it an effective tool for tracking and assessing the security of third-party software packages, libraries, and dependencies.

Software composition analysis (SCA) tools are used to identify open source components in code and check them against known vulnerability databases. While SCA is a valuable tool in a cybersecurity toolkit, it does not provide the comprehensive, detailed list of all components in a piece of software that an SBOM does.

The National Vulnerability Database (NVD) is a U.S. government repository of standards-based vulnerability management data. While it is a valuable resource for identifying known vulnerabilities, it does not provide the comprehensive, detailed list of all components in a piece of software that an SBOM does.

An intrusion detection system (IDS) is designed to monitor network traffic for suspicious activity and issue alerts when such activity is detected. While an IDS is an important part of a comprehensive cybersecurity strategy, it is not specifically designed to track and assess the security of third-party software packages.

q_vuln_scanning_scanners_secp8

Which of the following statements about network vulnerability scanners is true?

Answers:

- Network vulnerability scanners, such as Tenable Nessus and OpenVAS, are designed to test only servers and switches.
- Network vulnerability scanners only identify vulnerabilities but do not suggest any remediation techniques.
- Network vulnerability scanners do not depend upon a database of known software and configuration vulnerabilities.
- ***Network vulnerability scanners can test common operating systems, desktop applications, and server applications.**

Explanation:

Network vulnerability scanners are configured with information about known vulnerabilities and configuration weaknesses for typical network hosts. These scanners can test common operating systems, desktop applications, and server applications. This is useful for general-purpose scanning, but some types of applications might need more rigorous analysis.

The following statements about network vulnerability scanners are NOT true:

- Network vulnerability scanners like Tenable Nessus and OpenVAS are designed to test a variety of network hosts, including client PCs, mobile devices, servers, routers, and switches, not just servers and switches.
- Network vulnerability scanners not only identify vulnerabilities but also suggest remediation techniques. They compile a report about each vulnerability in their database that was found to be present on each host, categorize each identified vulnerability, assign an impact warning, and most tools also suggest remediation techniques.
- Network vulnerability scanners do depend upon a database of known software and configuration vulnerabilities. They use this database to identify vulnerabilities present on each host during the scanning process.

q_vuln_scanning_true_statement_secp8

Which of the following statements about vulnerability scanning is true?

Answers:

- Vulnerability scanning is a process of identifying, classifying, and ignoring vulnerabilities within a system or network.
- Network vulnerability scanners, such as Tenable Nessus and OpenVAS, are designed to test only servers and switches.
- Non-credentialed scans are more intrusive and provide a more in-depth analysis than credentialed scans.
- ***Package monitoring is a critical capability in application vulnerability assessment practices as it tracks and assesses the security of third-party software packages, libraries, and dependencies.**

Explanation:

Package monitoring is indeed a critical capability in application vulnerability assessment practices. It tracks and assesses the security of third-party software packages, libraries, and dependencies used within an organization to ensure that they are up-to-date and free from known vulnerabilities that malicious actors could exploit.

The following statements are NOT true:

- Vulnerability scanning is a process of identifying, classifying, remediating, and mitigating vulnerabilities within a system or network, not ignoring them.
- Network vulnerability scanners like Tenable Nessus and OpenVAS are designed to test a variety of network hosts, including client PCs, mobile devices, servers, routers, and switches, not just servers and switches.
- Non-credentialed scans are less intrusive than credentialed scans. Non-credentialed scans proceed by directing test packets at a host without being logged on to the OS or application, providing a view that the host exposes to an unprivileged user on the network. On the other hand, credentialed scans are given a user account with login rights to various hosts, allowing for a more in-depth analysis.

scan_vuln_cleartext_cve

Which CVE was reported for the discovered vulnerability?

Answers:

- ***CVE-2019-16645**
- CVE-2020-19841
- CVE-2022-05040
- CVE-2021-21101

Explanation:

The only CVE listed is CVE-2019-16645

scan_vuln_cleartext_solution

Which of the following are suggested possible solutions to remediate the vulnerability? (Select three)

Answers:

- ***Upgrade to a newer release**
- ***Remove the product**
- ***Replace the product with another one**
- Install patch 2.5.6.235
- Migrate users to a different service

scan_vuln_ftp_num

How many vulnerabilities were found on the FTP server?

Answers:

- ***2**
- 1
- 3
- 4

scan_vuln_ftp_components

Which of the following services or networking components were identified as being vulnerable? (Select two)

Answers:

- ***The FTP service**
- ***ICMP packet responses**
- The Apache webserver
- The SMB service
- The OpenSSH service

scan_vuln_tls_cve

Which CVEs were reported for the discovered vulnerability? (Select two)

Answers:

- CVE-2019-16645
- ***CVE-2011-3389**
- ***CVE-2015-0204**
- CVE-2021-2101
- CVE-2023-4311

Explanation:

The only CVE listed is CVE-2019-16645

scan_vuln_tls_solution

Which of the following are suggested possible solutions to remediate the vulnerability?

Answers:

- ***Disable TLSv1.0 and TLSv1.1 protocols in favor of the TLSv1.2+ protocols.**
- Remove TLS/SSL from the system
- Upgrade all clients to Windows 10+
- Encrypt all email

scan_vuln_linux_01

Which Linux computers were discovered by the scanner on IP address range 192.168.0.60 - 192.168.0.69?

Answers:

- ***192.168.0.60**
- 192.168.0.61
- ***192.168.0.62**
- 192.168.0.63
- 192.168.0.64
- ***192.168.0.65**
- 192.168.0.66
- 192.168.0.67
- ***192.168.0.68**
- 192.168.0.69

scan_vuln_linux_02

Which vulnerabilities are present on all the computers in the range? (Select two)

Answers:

- ***ICMP Timestamp Reply Information Disclosure**
- ***TCP Timestamps Information Disclosure**
- Cleartext Transmission of Sensitive Information via HTTP
- Telnet Unencrypted Cleartext Login
- VNC Server Unencrypted Data Transmission

scan_vuln_linux_03

For the Linux computer with the 192.168.0.60 IP address, which vulnerabilities should be remediated immediately? (Select two)

Answers:

- ***rlogin Passwordless Login**
- ***Operating System (OS) End of Life (EOL) Detection**
- TCP Timestamps Information Disclosure
- ICMP Timestamp Reply Information Disclosure

scan_vuln_linux_05

What is the recommended solution for the Telnet Unencrypted Cleartext Login vulnerability?

Answers:

- ***Replace Telnet with SSH**
- Update Telnet to latest version
- Use TLS v1.2+
- Update the SSL/TLS certificate

scan_vuln_linux_04

Which vulnerability has no known solution and will likely not get fixed?

Answers:

- ***GoAhead Server HTTP Header Injection Vulnerability**
- Cleartext Transmission of Sensitive Information via HTTP
- SSL/TLS: Deprecated TLSv1.0 and TLSv1.1 Protocol Detection
- Telnet Unencrypted Cleartext Login

7.3 Alerting and Monitoring

As you study this section, answer the following questions:

- What is the importance of monitoring a network?
- What tools are available to monitor a network for vulnerabilities?
- What role does SIEM play in network security?
- What is the risk of false positive alerts and alarms?

In this section, you will learn to:

- Analyze network traffic with Netflow.

The key terms for this section include:

Term	Definition

Network monitors	Collects data about network infrastructure appliances, such as switches, access points, routers, firewalls. This is used to monitor load status for CPU/memory, state tables, disk capacity, fan speeds/temperature, network link utilization/error statistics, and so on.
Netflow	A Cisco-developed means of reporting network flow information to a structured database.
System monitors	A system monitor implements the same functionality as a network monitor for a computer host. Like switches and routers, server hosts can report health status using SNMP traps.
System logs	Logs function both as an audit trail of actions and (if monitored regularly) provide a warning of intrusion attempts. Log review is a critical part of security assurance.
Vulnerability scanners	A vulnerability scanner will report the total number of unmitigated vulnerabilities for each host. Consolidating these results can show the status of hosts across the whole network and highlight issues with a particular patch or configuration issue.
Antivirus	Antivirus software detects malware by signature regardless of type, though detection rates can vary quite widely from product to product.
Data loss prevention	Data loss prevention (DLP) mediates the copying of tagged data to restrict it to authorized media and services.
Security information and event management (SIEM)	Software designed to manage security data inputs and provide reporting and alerting. The core function of a SIEM tool is to collect and correlate data from network sensors and appliance/host/application logs.
Reporting	A managerial control that provides insight into the security system's status.
Alert tuning	Correlation rules that reduce the incidence of false positive alerts and alarms.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	1.4 Explain the importance of using appropriate cryptographic solutions.

7.3.1 Alerting and Monitoring (Lesson Video)

Transcript:

Alerting and monitoring play a critical role in cybersecurity. Continuously monitoring systems and networks allow organizations to detect potential threats and breaches early. These monitoring systems trigger timely alerts, enabling security teams to take immediate action to isolate affected systems and implement recovery plans to protect crucial data.

Alerting and monitoring tools are used to generate alerts in real time. These tools often come equipped with dashboards for visualizing data. They also have advanced analytics capabilities for deeper insights into network security. There's a wide range of alerting and monitoring tools available. Let's take a moment to look at just a few.
First are network monitoring tools. These tools scrutinize and manage the functionality of a network. They help identify network bottlenecks and often predict potential issues before they become serious problems.
Next is a flow collector. Flow collectors are a means for recording metadata and statistics about network traffic rather than recording each frame. NetFlow is a network protocol developed by Cisco for collecting IP traffic information and monitoring network traffic.
System monitors provide information about the resources and performance of a system. They can monitor CPU usage, disk activity, and memory usage. System logs record the detailed operations of a system or network. They're critical for understanding system activities and identifying abnormalities.
Application and Cloud Monitors supervise the operation of applications and cloud-based services. They help ensure optimal performance and uptime while also tracking unusual activity. Vulnerability Scanners scan a system or network to identify any security weaknesses. They're an integral part of maintaining a secure IT environment, as they provide the first line of defense by identifying vulnerabilities before they can be exploited.

Data Loss Prevention (DLP) tools detect and prevent data breaches, exfiltration, or unwanted destruction of sensitive data. They also ensure that end users don't send sensitive or critical information outside the corporate network. Lastly, a SIEM, or Security Information and Event Management, is a comprehensive solution that provides real-time analysis of security alerts generated by networks and applications.
One of the functions of a vulnerability scan is to assess the configuration of security controls and application settings and permissions compared to established benchmarks. This is known as benchmarking. The scanner might try to identify whether there's a lack of controls that might be considered necessary or any system misconfiguration that would make the controls less effective or ineffective, such as antivirus software not being updated or management passwords left configured to the default. This testing requires specific information about best practices in configuring the application or security control.
These best practices are provided by listing the controls and appropriate configuration settings in a template.
Security Content Automation Protocol (SCAP) allows compatible scanners to determine whether a computer meets a configuration baseline. SCAP uses several components to accomplish this function.
Open Vulnerability and Assessment Language, or OVAL, is an XML schema describing system security state and querying vulnerability reports and information. Extensible Configuration Checklist Description Format, or XCCDF, is an XML schema for developing and auditing best practice configuration checklists and rules. Previously, best practice guides might've been written in prose for systems administrators to apply manually. XCCDF provides a machine-readable format that can be applied and validated using compatible software.
That's it for this lesson. In this lesson, we talked about alerting and monitoring. We reviewed several tools that can help with this. We also discussed the importance of establishing benchmarks for effective monitoring and alerting.

7.3.2 Alerting and Monitoring Facts

This lesson covers the following topics:

- Alerting and monitoring
- Alerting and monitoring tools

Alerting and Monitoring

Alerting and monitoring play a critical role in cybersecurity. Continuously monitoring systems and networks allow organizations to detect potential threats and breaches early. These monitoring systems trigger timely alerts, enabling security teams to take immediate action to isolate affected systems and implement recovery plans to protect crucial data.

Alerting and Monitoring Tools

The following chart describes several different commonly used alerting and monitoring tools:

Tool	Description
Network monitors	Distinct from network traffic monitoring, a network monitor collects data about network infrastructure appliances, such as switches, access points, routers, firewalls. This is used to monitor load status for CPU/memory, state tables, disk capacity, fan speeds/temperature, network link utilization/error statistics, and so on. Another important function is a heartbeat message to indicate availability. This data might be collected using the Simple Network Management Protocol (SNMP). An SNMP trap informs the management system of a notable event, such as port failure, chassis overheating, power failure, or excessive CPU utilization. The threshold for triggering traps can be set for each value. This provides a mechanism for alerts and alarms for hardware issues. As well as supporting availability, network monitoring might reveal unusual conditions that could point to some kind of attack.

Tool	Description

This is used to monitor load status for CPU/memory, state tables, disk capacity, fan speeds/temperature, network link utilization/error statistics, and so on. Another important function is a heartbeat message to indicate availability. This data might be collected using the Simple Network Management Protocol (SNMP). An SNMP trap informs the management system of a notable event, such as port failure, chassis overheating, power failure, or excessive CPU utilization. The threshold for triggering traps can be set for each value. This provides a mechanism for alerts and alarms for hardware issues. As well as supporting availability, network monitoring might reveal unusual conditions that could point to some kind of attack.
Netflow	A flow collector is a means of recording metadata and statistics about network traffic rather than recording each frame. Network traffic and flow data may come from a wide variety of sources (or probes), such as switches, routers, firewalls, and web proxies. Flow analysis tools can provide features such as the following: • Highlighting of trends and patterns in traffic generated by applications, hosts, and ports. • Alerting based on detection of anomalies, flow analysis patterns, or custom triggers. • Visualization tools that show a map of network connections and make interpretation of patterns of traffic and flow data easier. • Identification of traffic patterns revealing rogue user behavior, malware in transit, tunneling, or applications exceeding their allocated bandwidth. • Identification of attempts by malware to contact a handler or command & control (C&C) channel. NetFlow is a Cisco-developed means of reporting network flow information to a structured database. NetFlow has been redeveloped as the IP Flow Information Export (IPFIX) IETF standard (tools.ietf.org/html/rfc7011). A particular traffic flow can be defined by packets sharing the same characteristics, referred to as keys. A selection of keys is called a flow label, while traffic matching a flow label is called a flow record. A flow label is defined by packets that share the same key characteristics, such as IP source and destination addresses and protocol type. These five bits of information are referred to as a 5-tuple. A 7-tuple adds the input interface and IP type of service data. Each exporter caches data for newly seen flows and sets a timer to determine flow expiration. When a flow expires or becomes inactive, the exporter transmits the data to a collector.
System monitors and logs	A system monitor implements the same functionality as a network monitor for a computer host. Like switches and routers, server hosts can report health status using SNMP traps. Logs are one of the most valuable sources of security information. A system log can be used to diagnose availability issues. A security log can record both authorized and unauthorized uses of a resource or privilege. Logs function both as an audit trail of actions and (if monitored regularly) provide a warning of intrusion attempts. Log review is a critical part of security assurance. Only referring to the logs following a major incident is missing the opportunity to identify threats and vulnerabilities early and to respond proactively. Logs typically associate an action with a particular user. This is one of the reasons why it is critical that users do not share login details. If a user account is compromised, there is no means of tying events in the log to the actual attacker.

Tool	Description
Application and cloud monitors	SNMP offers limited functionality. There are numerous proprietary monitoring solutions for infrastructure, application, database, and cloud environments. Some are designed for on-premises and some for cloud, while some support hybrid monitoring of both types of environments. An application monitor will include a basic heartbeat test to verify that it is responding. Other factors to monitor include number of sessions and requests, bandwidth consumption, CPU and memory utilization, and error or security alert conditions. Cloud monitors will assess different facets of cloud services, such as network bandwidth, virtual machine status, and application health.
Vulnerability scanners	A vulnerability scanner will report the total number of unmitigated vulnerabilities for each host. Consolidating these results can show the status of hosts across the whole network and highlight issues with a particular patch or configuration issue.
Antivirus	Most hosts should be running some type of antivirus scan (A-V) software. While the A-V moniker remains popular, these suites are better conceived of as endpoint protection platforms (EPPs) or next-gen A-V. These detect malware by signature regardless of type, though detection rates can vary quite widely from product to product. Many suites also integrate with user and entity behavior analytics (UEBA) and use AI-backed analysis to detect threat actor behavior that has bypassed malware signature matching. Antivirus will usually be configured to block a detected threat automatically. The software can be configured to generate a dashboard alert or log via integration with a SIEM.
Data loss prevention	Data loss prevention (DLP) mediates the copying of tagged data to restrict it to authorized media and services. As with antivirus scanning, monitoring statistics for DLP policy violations can show whether there are issues, especially where the results show trends over time.

7.3.3 SIEM and SOAR (Lesson Video)

Transcript:

To protect our networks, we usually implement multiple automated devices such as IDSs, IPSs, firewalls, and security configurations. The problem with implementing these systems is that the amount of generated data becomes overwhelming for a human being to sort through. To help with this, we implement SIEM and SOAR systems. In this lesson, I'll go over each of these systems and how they work to help protect networks.

Security information and event management tools, or SIEM tools, work by gathering all sorts of information from a network and putting it together in one central location. More than just aggregating data, SIEM systems can also actively read all this information and determine if there's an actual threat! Let's see how this works.
Everything starts with the collectors. Log collectors are responsible for gathering event logs from security appliances, host systems, and applications. We can also add sensors to the system in order to capture network packets or data inputs from all the disparate systems on our network. This data is sent to the event collectors, and the event collectors send it all to the SIEM.
SIEM software takes this data, reads and analyzes it, and separates it into different categories such as logon attempts, database entries, port scans, network congestion, and more. You can review the reports to help find any suspicious network activity.
If data exceeds the defined thresholds of normal network activity, the SIEM sends an alert to the security administrator, who then can investigate it and take care of the threat as needed.
The next generation of SIEM systems are taking things to the next level. By implementing artificial intelligence and machine learning, these new systems can analyze user behavior and sentiment to determine if a threat exists. This can be used to detect threats like spear phishing attacks and insider threats.
SIEM systems are great at helping network administrators filter data and improve security monitoring. But, any alert still requires manual intervention.

The acronym SOAR stands for Security Orchestration, Automation, and Response. SOAR systems also gather and analyze data, but these systems take it to the next level. SOAR is a solution stack of compatible software programs that allow an organization to collect security-threat data from multiple sources and respond to low-level security events without human assistance. Let's break this down and see how these systems work.

SOAR systems gather the same information as SIEM systems do, but they also gather data from multiple third-party tools. The SOAR system coordinates these tools, sensors, and collectors to work together to gather as much relevant data as possible. This is the orchestration piece of a SOAR system.

You can set up a SOAR system to automate tasks that are routine, tedious, and time consuming, such as looking for and deleting phishing emails. This is usually configured using checklists called playbooks or a series of conditional steps called runbooks. Automating these tasks frees up time for your security team to focus on more important things.

Finally, a SOAR system is able to automatically respond to threats. For example, if malware is discovered, a SOAR system can identify the threat and quarantine it instead of just sending an alert.

SOAR systems help to reduce a security operation team's workload by automating workflows and handling low-level tasks automatically. You should use both SIEM and SOAR systems for improved security. Your SOAR system can likely respond to the low-level threats that the SIEM system uncovers, and your security team can take responsibility for the higher-level issues.

That'll wrap things up for now. In this lesson, we went over SIEM and SOAR systems. SIEM programs work by gathering all sorts of data from sensors and collectors. Then this data is analyzed, and alerts are sent out for potential threats. A SOAR system takes this one step further and is able to respond to low-level threats itself. You can configure SOAR systems to automate basic tasks that take up your organization's valuable time. Using both systems can greatly improve your network security.

7.3.4 SIEM and SOAR Facts

This lesson covers the following topics:

- Security Information and Event Management (SIEM)
- Alerting and monitoring activities
- Alerting
- Reporting
- Archiving
- Alert tuning

Security Information and Event Management (SIEM)

Software designed to manage security data inputs and provide reporting and alerting is often described as security information and event management (SIEM). The core function of a SIEM tool is to collect and correlate data from network sensors and appliance/host/application logs. In addition to logs from Windows and Linux-based hosts, this could include switches, routers, firewalls, IDS sensors, packet sniffers, vulnerability scanners, malware scanners, and data loss prevention (DLP) systems.

Collection is how the SIEM ingests security event data from various sources. There are three main types of security data collection:

- **Agent-based** —this approach means installing an agent service on each host. As events occur on the host, logging data is filtered, aggregated, and normalized at the host and then sent to the SIEM server for analysis and storage. Collection from Windows/Linux/macOS computers will use agent-based collection. The agent must run as a process and could use 50–500 MB of RAM, depending on the amount of activity and processing it does.
- **Listener/collector** —rather than installing an agent, hosts can be configured to push log changes to the SIEM server. A process runs on the management server to parse and normalize each log/monitoring source. This method is often used to collect logs from switches, routers, and firewalls, as these are unlikely to support agents. Some variant of the Syslog protocol is typically used to forward logs from the appliance to the SIEM.

- **Sensor** —as well as log data, the SIEM might collect packet captures and traffic flow data from sniffers. A sniffer can record network data using either a switch's mirror port functionality or some tap on the network media.

As distinct from collection, log aggregation refers to normalizing data from different sources to be consistent and searchable. SIEM software features connectors or plug-ins to interpret (or parse) data from distinct types of systems and to account for differences between vendor implementations. Each agent, collector, or sensor data source will require its own parser to identify attributes and content that can be mapped to standard fields in the SIEM's reporting and analysis tools. Another essential function is normalizing date/time zone differences to a single timeline.

Alerting and Monitoring Activities

When data has been collected and aggregated, the SIEM can implement alerting, reporting, and archiving activities. Note that these activities can be performed manually or automated using discrete tools for each security appliance. The advantage of a SIEM is to consolidate the activities into a single management interface. This consolidated functionality, referred to as a "single pane of glass," refers to the enhanced visibility into a complex environment that such software offers.

Alerting

Correlation means interpreting the relationship between individual data points to diagnose incidents of significance to the security team. A SIEM correlation rule is a statement that matches certain conditions. These rules use logical expressions, such as AND and OR, and operators, such as == (matches), < (less than), > (greater than), and in (contains). For example, a single-user login failure is not a condition that should raise an alert. Multiple user login failures for the same account, taking place within one hour, are more likely to require investigation and are a candidate for detection by a correlation rule.

Error.LoginFailure > 3 AND LoginFailure.User AND Duration < 1 hour

As well as the correlation between indicators observed in the collected data, a SIEM will likely be configured with a threat intelligence feed. This means that data points observed in the collected network data can be associated with known threat actor indicators, such as IP addresses and domain names.

Each alert will be dealt with by the incident response processes of analysis, containment, eradication, and recovery. When used in conjunction with a SIEM, two steps in alert response and remediation deserve particular attention:

- Validation during the analysis process is how the analyst decides whether the alert is a true positive and needs to be treated as an incident. A false positive generates an alert, but no actual threat activity exists.
- Quarantine isolates the source of indicators, such as a network address, host computer, or file.

Alert response and remediation steps will often be guided by a playbook that assists the analyst with applying all incident response processes for a given scenario. One of the advantages of SIEM and advanced security orchestration, authorization, and reporting (SOAR) solutions is to automate validation and remediation fully or partially. For example, a quarantine action could be available as a mouse-click action via an integration with a firewall or endpoint protection product. Validation is made easier by correlating event data to known threat data and pivoting between sources, such as inspecting the packets that triggered a particular IDS alert.

Reporting

Reporting is a managerial control that provides insight into the security system's status. A SIEM can assist with reporting activity by exporting summary statistics and graphs. Report formats and contents are usually tailored to meet the needs of different audiences:

- Executive reports provide a high-level summary for decision-makers. This guides planning and investment activity.

- Manager reports provide cybersecurity and department leaders with detailed information. This guides day-to-day operational decision-making.
- Compliance reports provide whatever information is required by a regulator.

Determining which metrics are most useful for reporting is always very challenging. The following types illustrate some common use cases for reporting:

- Authentication data, such as failed login attempts and critical file audit data.
- Hosts with missing patches and/or configuration vulnerabilities.
- Privileged user account anomalies include out-of-hours use or excessive requests for elevated permissions.
- Trend reporting to show changes to key metrics over time.

A SIEM can be used for two types of reporting:

- Alerts and alarms detect the presence of threat indicators in the data and can be used to start incident cases. Day-to-day management of alert reporting forms a large part of an analyst's workload.
- Status reports communicate data about the level of threat or number of incidents being raised and the effectiveness of security controls and response procedures. This type of reporting can be used to inform management decisions. It might also be required for compliance reporting.

A SIEM will ship with several preconfigured dashboards and reports, but it will also make tools available for creating custom reports. It is critical to tailor the information presented in a dashboard or report to meet the needs and goals of its intended audience. If the report contains an overwhelming amount of data or irrelevant information, it will not be possible to identify remediation actions quickly.

Archiving

A SIEM can enact a retention policy to keep historical log and network traffic data for a defined period. This allows for retrospective incident and threat hunting and can be a valuable source of forensic evidence. It can also meet compliance requirements to hold archives of security information. SIEM performance will degrade if excessive data is kept available for live analysis. A log rotation scheme can be configured to move outdated information to archive storage.

Alert Tuning

Correlation rules are likely to assign a criticality level to each match. Examples include the following:

- Log only — an event is produced and added to the SIEM's database, but it is automatically classified.
- Alert — the event is listed on a dashboard or incident handling system for an agent to assess. The agent analyzes the event data and either dismisses it to the log or validates it and starts an incident case.
- Alarm — the event is automatically classified as critical, and a priority alarm is raised. This might mean emailing an incident handler or sending a text message.

Alert tuning is necessary to reduce the incidence of false positives. False positive alerts and alarms waste analysts' time and lower productivity. Alert fatigue is when analysts are so consumed with dismissing numerous low-priority alerts that they miss a single high-impact alert that could have prevented a data breach. Analysts can become more preoccupied with looking for a quick reason to dismiss an alert than with adequately evaluating the alert. Reducing false positives is difficult, however, firstly because there is not a simple dial to turn for overall sensitivity and secondly because reducing the number of rules that produce alerts increases the risk of false negatives.

There is also a concept of true negatives. This is a measure of events that the system has properly allowed. Metrics for false and true negatives can be used to assess the performance of the alerting system.

Some of the techniques used to manage alert tuning include the following:

- Refining detection rules and muting alert levels — If a particular rule generates multiple dashboard notifications, the rule's parameters can be adjusted to reduce this, perhaps by adding more correlation factors. Alternatively, the alert can be muted to log-only status or configured only to produce a single notification for every 10 or 100 events.
- Redirecting sudden alert "floods" to a dedicated group — Changes in the network can cause a rule to produce far more alerts than it should. Once confirmed that this is a false positive, rather than "spamming" each analyst's dashboard, it can be assigned to a dedicated agent or team to remediate.
- Redirecting infrastructure-related alerts to a dedicated group — Misconfigurations, such as deviance from a baseline, can cause continually high alert volumes. While these are important to fix, that is not the job of the incident response team and is better managed by an infrastructure team.
- Continuous monitoring of alert volume and analyst feedback — Managers should oversee the system and be aware of risks from alert fatigue. The experience of individual analysts can be utilized to reduce alert sensitivity, change the parameters of a given rule, or automate the processing of the rule using a SOAR solution.
- Deploying machine learning (ML) analysis — ML can rapidly analyze the data sets produced by SIEM. It can be used to monitor how analysts respond to alerts and attempt to automatically tune the ruleset to reduce false negatives without impacting true positives.

7.3.5 Analyze Network Traffic with Netflow (Demo Video)

Transcript:

NetFlow is a network protocol system originally created by Cisco. Netflow collects active IP network traffic as it flows in or out of an interface. The data is gathered and then analyzed to create a picture of network traffic flow and the volume of traffic.

So, why do we use Netflow? Well the NetFlow protocol is used by IT professionals as a network traffic analyzer to determine its point of origin, it's destination, the volume and the paths on the network. Before NetFlow's creation, network IT engineers and administrators would use Simple Network Management Protocol (SNMP) for network traffic analysis and monitoring.
Although Netflow is a feature was created by Cisco, there are open-source alternatives such as softflowd that can be installed to work with pfsense. This will allow us to capture network traffic and create a picture to better analyze in and out traffic.
In order to use softflowd we must install it from the package list. To do so we need to go to system then package manager. Tab over to Available packages. Just to make it easier so were not scrolling for a while type 'softflow' in the search bar and click search. Next, we can click the Install button and then confirm. When the software is installed successfully, we can then configure it.
To adjust our settings for softflowd we need to go to services, then softflowd. Make sure at the top it says enabled, Interface can either be LAN or WAN depending on what side of the firewall you would like to capture the data. It is possible to grab data from both if you would like however were just going to select WAN for now. The Host will be the NetFlow analyzer which happens to be '192.168.30.202' on our network. Port will the designated port of your choosing. Sometimes it is a good idea to use an alternative port for security purposes, but for now were using the standard '2055' port for NetFlow. We will leave the max flows to the default '8192'. The NetFlow version will depend on your analyzer's capability. If it doesn't support version ten then you may want to see what version, it does support. I'm going to flip this to version '9' because that is what our analyzer supports. Click save at the bottom.
Even though our settings are saved we want to make sure things are working right. There is a command line command you can run to show statistics on softflowd. Go to diagnostics then command prompt. In the Execute shell command field we can insert our command 'softflowctl -c /var/runsoftflowd.vmx0.ctl statistics'. The part that has vmx0 may differ if your network interface is labeled differently. Execute that command and now we can see some results. You may not a lot of traffic yet however you may want to check back later to verify flow packets and byte counts are going up. Now we are ready to send and configure NetFlow to our analyzer.
That is, it for this demo, in this demo we installed and configured softflowd.

7.3.6 Data Loss Prevention (Lesson Video)

Transcript:

Every business has sensitive data in its system, and protecting it is a high priority. A data leakage incident happens when sensitive data like credit card numbers, intellectual property, financial information, or proprietary company information is disclosed to an unauthorized person. In this lesson, we'll look at five approaches to data security, including data loss prevention, or DLP; masking; encryption; tokenization; and rights management.

Data can exist in one of three states, and it's important to use the right security approach for each state. The first state is while the data is in use on an endpoint system, like a workstation. The second state is while the data is in motion, such as when it's transmitted over the network or to the cloud. The third state is while the data rests on a storage medium, like a hard disk drive, or in a database.

Let's look at data protection through a DLP system. A DLP system works like a guard at the perimeter of your network, allowing unsensitive data to leave, but restricting sensitive data from being transmitted out of the company. A DLP analyzes the network traffic in accordance with the organization's security policies.

For example, an e-commerce retailer could use a network DLP solution to monitor for files containing credit card numbers. If one of those files were being transmitted out of the company, the DLP software would flag it as a potential security problem.

Next, let's look at the masking approach. Masking works by replacing sensitive data with realistic fictional data. There are different types of masking. We'll look at dynamic data masking, and then we'll look at static data masking.

Let's start with dynamic. Dynamic masking replaces original information with a mask that mimics the original in form and function, making it useful for data that's in use or in processing. For example, someone's name would be replaced with another name, or credit card numbers would be replaced with a random number that contains the same number of characters.

This method can be used to control which users can see the actual data. A bank could have third-party analytics performed on their accounts while masking the account numbers and clients' names. With dynamic data masking, the original data can be retrieved.

Another type of masking is static data masking. This type is helpful for data at rest in a database and can be specified by field or column. You may want to use this method if you're making copies of a database for testing, development, or reporting. The complex algorithms in static masking make the original data irretrievable through reverse-engineering, so making a masked copy may be a better choice than masking the original database.

All right. Next, let's briefly review encryption. Encryption happens when an algorithm changes plain text data into unreadable ciphertext. The encryption algorithm has a variable that's called a key. The authorized user that receives the encrypted data can decrypt it through the cipher key. This helps to protect data in motion.

Now let's look at a tokenization approach. Tokenization is similar to encryption and masking--it replaces actual data with something else. But tokenization uses a randomly generated alphanumeric character set called a token to replace the original data. The token server stores the original data and is protected by security measures like authentication and authorization protocols so that the original information is disclosed only when the correct token is presented. This method is frequently used for credit card numbers, bank accounts, medical records, and other personally identifiable information.

For example, when you have a credit card number stored on your mobile phone through an app, the app connects with the remote token server, which creates the token and replaces the credit card number stored in your phone.

Then, when you go to use your phone's app to pay for your purchase at the store, the store's point of sale terminal will contact a merchant acquirer. The merchant acquirer presents the token value to the remote token server. The server uses the token to map back to your actual credit card number and authorize the purchase. An authorization is sent to the merchant, and a message from the server is sent to your phone.

Finally, we have rights management. Rights management is data protection at the file level. With rights management, you identify sensitive files in the file system and embed them with your organization's security policy. The key benefit of this approach is that the security policy travels with the specific file even if it's moved or copied. You can continue to control access to the file, such as restricting who it can be transferred to, even when the file is no longer on your system.

Rights management falls into two categories: Digital Rights Management, or DRM, and Information Rights Management, or IRM.

DRM is file level management applied to rich media like music, videos, and software. This strategy uses security technologies such as encryption, permissions, product keys, limited install applications, and persistent online authentication to prevent editing, sharing, and unauthorized copying. The purpose is to protect copyrighted media and

software. For example, when a consumer purchases a software program, the program is not accessible without a product key provided by the manufacturer at the time of purchase. An example of continuous online authentication is when a consumer logs in to an online application or streams the information through an account that requires authentication.
Now let's move on to IRM, or Information Rights Management. It's also called Enterprise Rights Management sometimes. It focuses on business-to-business transfers for files such as documents, emails, spreadsheets, and financial data. Information rights management utilizes encryption and permissions to create rules for the files, which can allow or deny copying and pasting, editing, forwarding, and printing. An example is a contract document that only the recipient can open and digitally sign and is denied forwarding abilities.
That's it for this lesson. In this video, we review five approaches to data protection. First, we looked at data loss prevention. Next, we discussed two types of masking, dynamic and static. We talked about encryption, which uses a cipher with a key to encode information that can be decoded with a key by the receiver. Next, we discussed tokenization, which uses an alphanumeric value as a token to replace sensitive information that's protected by the token server. And finally, we went over rights management, which protects data through permissions at the file level that stay with the file even if it leaves your network.

7.3.7 DLP Facts

This lesson covers the following topics:

- Data loss prevention (DLP)

Smaller organizations might classify and type data manually to apply data guardianship policies and procedures. However, an organization that creates and collects large amounts of personal data usually needs automated tools to assist with this task. Protecting valuable intellectual property (IP) data may also be required. Data loss prevention (DLP) products automate the discovery and classification of data types and enforce rules so that data is not viewed or transferred without proper authorization. Such solutions will usually consist of the following components:

- Policy server — to configure classification, confidentiality, and privacy rules and policies, log incidents, and compile reports.
- Endpoint agents — to enforce policy on client computers, even when they are not connected to the network.
- Network agents — to scan communications at network borders and interface with web and messaging servers to enforce policy.

DLP agents scan content in structured formats, such as a database with a formal access control model, or unstructured formats, such as email or word processing documents. A file cracking process is applied to unstructured data to render it in a consistent scannable format. The transfer of content to removable media, such as USB devices, by email, instant messaging, or even social media, can be blocked if it does not conform to a predefined policy. Most DLP solutions can extend the protection mechanisms to cloud storage services, using either a proxy to mediate access or the cloud service provider's API to perform scanning and policy enforcement.

Remediation is the action the DLP software takes when it detects a policy violation. The following remediation mechanisms are typical:

- Alert only — copying is allowed, but the management system records an incident and may alert an administrator.
- Block — the user is prevented from copying the original file but retains access. The user may or may not be alerted to the policy violation, but it will be logged as an incident by the management engine.
- Quarantine — access to the original file is denied to the user (or possibly any user). This might be accomplished by encrypting the file or moving it to a quarantine area in the file system.
- Tombstone — the original file is quarantined and replaced with one describing the policy violation and how the user can re-release it.

When configured to protect a communications channel such as email, DLP remediation might take place using client-side or server-side mechanisms. For example, some DLP solutions prevent attaching files to the email before sending it. Others might scan the email attachments and message content, strip out specific data, or stop the email from reaching its destination.

7.3.8 Practice Questions (Section Quiz)

q_alert_monitoring_antivirus_secp8

A software technician is upgrading the alerting and monitoring tools for the organization's infrastructure and wants to employ new software to assist in detecting and removing infectious files and other forms of malware.

What type of software can the technician purchase to achieve this protection?

Answers:

- ***Antivirus (A-V)**
- Security content automation protocol
- Simple Network Management Protocol (SNMP) trap
- Data loss prevention

Explanation:

Antivirus (A-V) software can detect and remove infections and (in most cases) other types of malware, such as worms, Trojans, rootkits, adware, spyware, password crackers, network mappers, and denial-of-service (DoS) tools.

Security content automation protocol (SCAP) allows compatible scanners to determine whether a computer meets a configuration baseline.

A Simple Network Management Protocol (SNMP) trap informs the management system of a notable event, such as port failure, chassis overheating, power failure, or excessive central processing unit (CPU) utilization.

Data loss prevention (DLP) mediates the copying of tagged data to restrict it to authorized media and services and monitors statistics for policy violations.

q_alert_monitoring_application_secp8

Which tool assesses different facets of cloud services, such as network bandwidth, virtual machine status, and program health in a network environment?

Answers:

- Vulnerability scanner
- System monitor
- ***Application monitor**
- Data loss prevention (DLP) tool

Explanation:

An application monitor assesses an application's health, performance, and functionality, ensuring its smooth operation and detecting any potential issues.

A vulnerability scanner identifies and reports unmitigated vulnerabilities on hosts, aiding in the assessment of system security status. However, its primary focus is not evaluating application health or cloud services.

A system monitor is a hardware or software component used to monitor system resources and performance in a computer system. However, its primary focus is not evaluating application health or cloud services.

DLP tools constantly monitor and analyze data to identify potential violations of security policies and, if appropriate, stop them from continuing. However, its primary focus is not evaluating application health or cloud services.

q_alert_monitoring_continuous_secp8

A manufacturing company's security manager plans to implement corrective operational controls to mitigate potential security threats.

Which of the following instances would be the appropriate control?

Answers:

- ***Enabling continuous monitoring to disable abnormal accounts.**
- Regular penetration testing to uncover potential vulnerabilities.
- A firewall that prevents unauthorized access to the network.
- A security camera system monitoring the premises.

Explanation:

Enabling continuous monitoring to disable abnormal accounts is a corrective operational control. When detecting abnormal behavior, this control disables the account to prevent unauthorized access.

Penetration testing is more of a detective control than a corrective one. It identifies vulnerabilities but does not correct them directly.

A firewall is primarily a preventive control, not a corrective one. Its main function is to stop unauthorized access before it happens rather than correcting issues after they occur.

Security cameras are typically a deterrent and detective type of physical control, not an operational one. They can deter potential intruders and detect security incidents, but they do not correct issues directly.

q_alert_monitoring_flow_secp8

A company's IT department has noticed irregularities in network usage and resource allocation.

Which tool would be MOST beneficial in identifying patterns in network traffic, detecting anomalies, and visualizing network connections?

Answers:

- ***Flow collector**
- Network monitor
- SNMP trap
- Heartbeat message

Explanation:

Flow collectors record metadata and statistics about network traffic, thereby identifying trends and patterns, detecting anomalies, and providing visualization tools that simplify the interpretation of traffic data.

While network monitors can provide valuable information on the state of network appliances, they primarily focus on aspects like CPU/memory load status, disk capacity, network link utilization, and similar data.

Simple Network Management Protocol (SNMP) traps inform a management system of notable events, such as port failures or excessive CPU utilization, primarily dealing with hardware issues rather than traffic pattern analysis.

A heartbeat message indicates availability and does not directly analyze or interpret network traffic.

q_alert_monitoring_log_files_01_secp8

A digital forensics analyst at a healthcare company is investigating a case involving a potential internal data breach. The breach has led to unauthorized access and potential exposure of sensitive patient information.

The company uses a Security Information and Event Management (SIEM) tool that aggregates and correlates data from multiple sources. The analyst's task is to identify potential insider threats that could be responsible for the breach.

Given the nature of the breach, which combination of data sources should the analyst primarily consider for their investigation?

Answers:

- ***Log files generated by the OS components of client and server host computers, logs generated by applications and services running on hosts, and endpoint logs.**
- Packet captures system memory metadata and logs generated by endpoint security software installed on hosts.
- Log files generated by network appliances like switches, routers, and firewalls; application logs; and automated reports from the SIEM tool.
- Network traffic captured by sensors, logs generated by network-based vulnerability scanners, and firewall logs.

Explanation:

Client and server host operating system (OS) logs reveal system-level activities, while application and endpoint logs provide application usage and end-user activity insights. This combination identifies potential insider threats and provides a comprehensive view.

Packet captures and system memory metadata provides network and system activity data. Endpoint security logs reveal end-user threats.

Network appliance logs provide network activity insights, while application logs reveal unauthorized access or usage anomalies. System Information and Event Management (SIEM) tool reports summarize incidents but may miss system-level and endpoint activities.

Sensors capture detailed network activity views. Vulnerability scanner logs reveal exploitable vulnerabilities, while firewall logs provide traffic insights. However, this may need to include system-level and application activities.

q_alert_monitoring_log_files_02_secp8

A security operations analyst at a financial institution analyzes an incident involving unauthorized transactions. The analyst suspects that a malware infection on one of the endpoints might have led to the unauthorized access.

To identify the root cause and trace the activities of the suspected malware, which combination of data sources should the analyst primarily consider?

Answers:

- ***Endpoint logs, log files generated by the OS components of the affected host computer, and logs from the host-based intrusion detection system.**
- Network logs, packet captures, and logs generated by network-based vulnerability scanners.
- Firewall logs, system memory metadata, and automated reports from the SIEM tool.
- Logs from applications involved in the transactions, logs generated by the host's antivirus software, and /var/log/auth.log for authentication and authorization data.

Explanation:

Endpoint logs and operating system (OS) component log files comprehensively view potential malware activities on the affected end-user system.

Network logs, packet captures, and vulnerability scanner logs provide a network-level view but might not cover all system-level and application activities.

Firewall logs, system memory metadata, and System Information and Event Management (SIEM) reports provide network and system insights but might not cover all application-level activities.

Application logs and antivirus logs give insights into application usage and threats but might not apply to all hosts and could potentially miss network activities.

q_alert_monitoring_netflow_01_secp8

A network administrator at a large tech company has the task of enhancing the visibility into network traffic patterns in a distributed enterprise network.

The administrator wants to implement a solution that captures metadata and statistics about network traffic without recording each frame, with the goal of improving the company's security measures.

Which tool should the administrator consider implementing?

Answers:

- ***A NetFlow collector**
- A vulnerability scanner
- A simple network management protocol (SNMP) trap
- A data loss prevention

Explanation:

A NetFlow collector is the best solution. The NetFlow protocol collects and records metadata and statistics about network traffic, providing administrators with insights into traffic patterns.

A vulnerability scanner identifies security weaknesses in the network but does not capture metadata and statistics about network traffic.

A Simple Network Management Protocol (SNMP) trap alerts administrators of notable events in network devices in real time but does not capture metadata and statistics about network traffic.

A data loss prevention (DLP) system prevents data breaches by detecting potential data exfiltration transmissions but does not capture metadata and network traffic statistics.

q_alert_monitoring_netflow_02_secp8

A security analyst is monitoring a web application for potential security issues. After observing unusual behavior, the analyst wants to identify the source of the issue.

Which strategy would MOST effectively identify patterns revealing rogue user behavior, malware in transit, tunneling, or applications exceeding their allocated bandwidth?

Answers:

- ***Deploying a NetFlow collector to analyze network traffic related to the web application.**
- Implementing simple network management protocol (SNMP) traps in the web application.
- Using a vulnerability scanner to scan the web application.
- Installing an additional security information and event management (SIEM) system to handle the data from the web application.

Explanation:

The best strategy is to deploy a NetFlow collector to analyze network traffic related to the web application. NetFlow collectors capture metadata and statistics about network traffic to identify patterns and anomalies.

Implementing Simple Network Management Protocol (SNMP) traps in the web application is not the right approach. SNMP traps alert notable events in network devices but not patterns in web application traffic.

A vulnerability scanner can identify security weaknesses in the web application but may not effectively identify real-time traffic patterns related to the application.

Installing an additional SIEM system is unnecessary. A SIEM system can aggregate and analyze data from various sources, but a NetFlow collector can more effectively analyze network traffic patterns related to a specific application.

q_alert_monitoring_snmp_trap_secp8

After experiencing a catastrophic server failure in the headquarters building, what can the company use to monitor notable events such as port failure, chassis overheating, power failure, or excessive central processing unit (CPU) utilization?

Answers:

- ***Simple network management protocol (SNMP) trap**
- Data loss prevention
- Antivirus (A-V)
- Security content automation protocol

Explanation:

A Simple Network Management Protocol (SNMP) trap informs the management system of a notable event such as port failure, chassis overheating, power failure, or excessive central processing unit (CPU) utilization.

Data loss prevention (DLP) mediates the copying of tagged data to restrict it to authorized media and services and monitors statistics for policy violations.

Antivirus (A-V) software detects and removes infections and (in most cases) other types of malware, such as worms, Trojans, rootkits, adware, spyware, password crackers, network mappers, and denial of service (DoS) tools.

Security content automation protocol (SCAP) allows compatible scanners to determine whether a computer meets a configuration baseline.

q_siem_soar_alerts_and_alarms_secp8

As a cybersecurity analyst, you are responsible for monitoring the organization's security information and event management (SIEM) system. Your team has recently noticed an increase in suspicious network activity.

What type of SIEM reporting should you prioritize to effectively manage this situation?

Answers:

- Executive reports providing a high-level summary for decision-makers.
- Compliance reports providing information required by a regulator.
- ***Alerts and alarms detecting the presence of threat indicators in the data.**
- Status reports communicating data about the level of threat or number of incidents being raised.

Explanation:

Alerts and alarms detecting the presence of threat indicators in the data is the correct answer. In a situation where suspicious network activity is increasing, prioritizing alerts and alarms can help the team quickly identify and respond to potential threats. This type of reporting provides real-time information about potential security incidents, allowing for immediate action.

While executive reports provide a high-level summary for decision-makers and are important for informing strategic decisions, they may not provide the immediate, detailed information needed to address an increase in suspicious network activity.

Compliance reports providing information required by a regulator are crucial for maintaining regulatory compliance, but they may not provide the real-time, actionable information needed to respond to an immediate threat.

Status reports communicating data about the level of threat or number of incidents being raised can provide useful context about the overall security situation, but they may not provide the immediate, detailed information needed to respond to an increase in suspicious activity.

q_siem_soar_alert_response_secp8

A senior security analyst is refining the incident response processes for a large organization that recently implemented a security information and event management (SIEM) system. During a simulation of a cybersecurity incident, the analyst observed that the SIEM system generated several alerts that were false positives, leading to unnecessary consumption of resources.

On which step should the analyst focus to improve the efficiency of the alert response and remediation process?

Answers:

- ***Enhancing the validation and quarantine processes in the alert response**
- Increasing the number of correlation rules in the SIEM system

- Implementing additional threat intelligence feeds in the SIEM system
- Increasing the frequency of SIEM system reporting to capture more incidents

Explanation:

The analyst should focus on enhancing validation and quarantine processes in alert response. Validation reduces false positives, while quarantine isolates the source of indicators to manage potential incidents.

Simply increasing the number of correlation rules in the SIEM system is not the right solution, as it could lead to more false positives if not done judiciously.

Adding additional threat intelligence feeds in the SIEM system does not directly address false positives and could cause data overload and more false positives.

Increasing SIEM system reporting frequency does not directly improve alert response and remediation efficiency, as it does not address false positives in alerting.

q_siem_soar_collector_secp8

Which SIEM component is responsible for gathering all event logs from configured devices and securely sending them to the SIEM system?

Answers:

- Data handling
- SIEM alerts
- ***Collectors**
- Security automation

Explanation:

Collectors are responsible for gathering all event logs from configured devices and securely sending them to the security information and event management (SIEM) system. Collectors are basically the middleman between devices and the SIEM system.

The data handling component receives the data from the collectors and then reads, analyzes, and separates the data into different categories.

SIEM alerts are responsible for triggering alerts if any data exceeds the established thresholds.

Security automation is a feature of a SOAR system.

q_siem_soar_correlation_rule_secp8

A cybersecurity analyst uses a security information and event management (SIEM) tool to monitor network activity in a large organization.

During a shift, the analyst receives multiple alerts indicating the same user account is experiencing multiple login failures within the span of an hour.

Which of the following correlation rules likely triggered this alert?

Answers:

- Error.LoginFailure > 1 AND LoginFailure.User AND Duration < 1 day
- ***Error.LoginFailure > 3 AND LoginFailure.User AND Duration < 1 hour**
- Error.LoginFailure > 5 AND LoginFailure.User AND Duration < 30 minutes
- Error.LoginFailure > 2 AND LoginFailure.User AND Duration < 2 hours

Explanation:

Error.LoginFailure > 3 AND LoginFailure.User AND Duration < 1 hour - This correlation rule accurately represents the scenario described, which involves multiple login failures from the same user account within an hour.

Error.LoginFailure > 1 AND LoginFailure.User AND Duration < 1 day - While this correlation rule will flag repeated login failures, it is not as precise as the rule described in the scenario, specifically looking for more than three failures within one hour.

Error.LoginFailure > 5 AND LoginFailure.User AND Duration < 30 minutes - This correlation rule is stricter than the scenario described. It is looking for more than five login failures within 30 minutes, while the scenario involves multiple failures within an hour.

Error.LoginFailure > 2 AND LoginFailure.User AND Duration < 2 hours - This correlation rule is less precise than the one in the scenario. It looks for more than two failures within two hours, which is a broader timeframe than specified in the scenario.

q_siem_soar_detection_rules_secp8

A company tasks a cybersecurity manager with improving the efficiency of its security information and event management (SIEM) system.

The manager observes that the high number of false positive alerts causes alert fatigue among the analysts, potentially leading them to miss high-impact alerts.

Which combination of strategies should the manager consider implementing to tackle this issue effectively?

Answers:

- ***Refine detection rules, redirect sudden alert "floods" to a dedicated group, and continuously monitor alert volume and analyst feedback.**
- Assign all infrastructure-related alerts to the incident response team and increase the frequency of system reporting.
- Mute all alerts to log-only status and deploy additional threat intelligence feeds in the SIEM system.
- Increase the number of correlation rules and assign all alerts to a dedicated agent or team to remediate.

Explanation:

The best strategy is to refine detection rules, redirect sudden alert "floods" to a dedicated group, and continuously monitor alert volume and analyst feedback to address false positives and alert fatigue.

Assigning all infrastructure-related alerts to the incident response team is not the right approach. The infrastructure team should manage these alerts. Increasing system reporting frequency does not directly address false positives.

Muting all alerts to log-only status could lead to missed alerts. Deploying additional threat intelligence feeds does not directly address false positives.

Increasing the number of correlation rules does not necessarily reduce false positives and could increase them. Assigning all alerts to a dedicated agent or team does not specifically address false positives.

q_siem_soar_device_logs_secp8

A security administrator reviews the configuration of a newly implemented security information and event management (SIEM) system. The SIEM system collects and correlates data from various sources, such as network sensors, application logs, and host logs.

The administrator notices that some network devices, like switches and routers, do not directly support the installed agents for data collection.

What approach should the administrator consider to ensure the inclusion of these devices' logs in the SIEM system?

Answers:

- ***Configuring the devices to push log changes to the security information and event management (SIEM) server using a listener/collector approach**
- Implementing an additional data loss prevention (DLP) system for these devices
- Installing additional security information and event management (SIEM) servers to handle the data from these devices
- Running a vulnerability scanner on these devices to ensure they are compliant with the security information and event management (SIEM) system

Explanation:

Using a listener/collector approach to push log changes from switches, routers, and firewalls to the SIEM server is a good approach. A listener/collector approach includes logs from devices that do not support agents in the SIEM server.

An additional data loss prevention (DLP) system is not the appropriate solution for collecting logs from devices that do not support installed agents.

Installing additional SIEM servers is unnecessary since the problem relates to the method of log collection, not the capacity of the SIEM server.

Running a vulnerability scanner on these devices does not solve the log collection problem, as vulnerability scanners identify security weaknesses, not enable log collection for SIEM systems.

q_siem_soar_login_failures_secp8

An information security manager is fine-tuning a security information and event management (SIEM) system in a company that has recently experienced multiple cybersecurity incidents. The manager wants to ensure prompt detection of potential incidents for immediate investigation.

Which approach should the manager consider to optimize the system's alerting capability?

Answers:

- ***Configure the SIEM system to alert when multiple login failures for the same account occur within a specified time period.**
- Set the SIEM system to generate an alert for every single-user login failure.
- Enable the SIEM system to send an alert for every received threat intelligence feed.
- Arrange the SIEM system to archive all historical log data for retrospective incident and threat hunting.

Explanation:

The best approach is to configure the SIEM system to alert when multiple login failures for the same account occur within a specified time period, using correlation to interpret the relationship between data points and diagnose incidents for the security team.

Setting the SIEM system to generate an alert for every single-user login failure is not the right approach. This could lead to a high number of false positives.

Sending an alert for every received threat intelligence feed is not effective, as not all data may signify a potential incident.

Archiving is valuable for forensic analysis and compliance but does not address prompt detection of potential incidents.

q_siem_soar_logs_secp8

A security compliance manager at a large manufacturing company is investigating noncompliance incidents related to baseline security configurations across various hosts. The focus is identifying missing patches, understanding historical vulnerabilities, and assessing host configuration.

The manager needs to differentiate between remediated and unremediated vulnerabilities and correlate the findings with the date of the last scan.

What approach would BEST provide the required information for this investigation?

Answers:

- ***Utilize vulnerability scans and retrieving logs from a security event and incident management (SIEM).**
- Analyze network logs and application logs.
- Review packet captures and endpoint logs.
- Inspect operating system (OS)-specific security logs and automated reports.

Explanation:

Utilizing vulnerability scans and retrieving logs from a system information and event management (SIEM) would detect missing patches and noncompliance with baseline security configurations. The SIEM's ability to retrieve a list of logs for each host, with the date of the last scan, aligns with the investigation's objectives.

Generally, analyzing network and application logs doesn't provide specific details about missing patches and baseline security compliance.

Reviewing packet captures and endpoint logs offers details about network traffic and device activities but needs more depth for understanding historical vulnerabilities and baseline compliance.

Inspecting operating system (OS)-specific security logs and automated reports may provide general security information but need a detailed understanding of missing patches, noncompliance, and remediation status related to baseline configurations.

q_siem_soar_log_aggregation_secp8

A security analyst is optimizing a multinational company's security information and event management (SIEM) system. The system collects security event data from sources globally, and the analyst has noticed inconsistencies due to different time zones.

What should the analyst consider to ensure a consistent timeline across all logs for accurate event correlation?

Answers:

- ***Adjusting the log aggregation process in the SIEM system to normalize date/time zone differences.**
- Configuring the SIEM system to only collect data during the company's standard business hours.
- Implementing additional packet sniffers to collect network data uniformly.
- Installing agents on all data sources to ensure synchronization with the SIEM server's time zone.

Explanation:

Adjusting the log aggregation process in the SIEM system to normalize date/time zone differences is necessary. Normalizing date/time zone differences to a single timeline is an important function of the log aggregation process in a SIEM system.

Configuring the SIEM system to collect data only during business hours will not fix time zone inconsistencies and may cause the company to miss important security events.

Implementing additional packet sniffers to collect network data uniformly does not address the problem of time zone inconsistencies. Packet sniffers collect network data.

Installing agents on data sources for synchronization with the SIEM server's time zone does not fix the issue, as agents do not handle date/time zone normalization.

q_siem_soar_log_correlation_secp8

To optimize the enterprise security information and event management (SIEM) solution, a multinational 's chief information security officer (CISO) is strategizing. The SIEM system acquires data from diverse sources, including Linux and Windows servers, advanced switches, Next Generation Firewalls (NGFWs), and routers.

Which feature should the CISO prioritize improving in the SIEM solution to standardize the data and enhance its searchability?

Answers:

- ***Augmenting the log correlation mechanism in the SIEM solution.**
- Elevating the SIEM solution's threat-hunting capabilities.
- Upgrading the network-based data collection method in the SIEM solution.
- Integrating additional intrusion detection systems (IDS) into the network.

Explanation:

The most relevant improvement is augmenting the log correlation mechanism in the SIEM solution. Log correlation standardizes and makes data from various sources more searchable, directly addressing the CISO's objective.

Elevating the threat-hunting capabilities of the SIEM solution is crucial, but it does not directly influence the standardization and searchability of data from diverse sources.

Upgrading the network-based data collection method in the SIEM solution is not optimal. While this method assists in data collection, it does not directly address the issue of making data more standardized and searchable.

Integrating additional IDS into the network does not resolve the problem. While IDS collects network data, it does not directly contribute to standardization of data from diverse sources.

q_siem_soar_os_logs_secp8

A security operations center (SOC) manager notices a significant increase in unclassified events on the incident handler's security event and incident management (SIEM) dashboard. At the same time, someone or something raises the number of incidents.

The manager investigates these incidents further to ensure efficient and timely incident response.

Which combination of data sources would provide the MOST comprehensive view to support the manager's investigation?

Answers:

- ***OS-specific security logs, log files generated by applications and services running on hosts, and automated reports from the SIEM tool.**
- Firewall logs, network traffic captured by sensors, and log files generated by OS components of server host computers.
- Endpoint logs, automated reports from the SIEM tool, and metadata.
- Log files from network-based vulnerability scanners, application logs, and endpoint logs.

Explanation:

Operating system (OS)-specific security logs reveal system-level activities, while application and service logs on hosts provide application activity information. security information and event management (SIEM) tool reports summarize incidents, offering a balanced combination for comprehensive investigations.

Firewall logs and sensors provide detailed network activity views, while server-host OS logs offer server-side insights. However, this may not cover endpoint or application activities.

Endpoint logs reveal end-user system activities, and SIEM tool reports summarize incidents. However, metadata may need to provide more detail for thorough investigations.

Network-based vulnerability scanner logs show potential vulnerabilities, while application and endpoint logs reveal application and end-user system activities. However, this may not cover network-level activities.

q_siem_soar_playbook_secp8

Which of the following security orchestration, automation, and response (SOAR) system automation components is often used to document the processes and procedures that are to be used by a human during a manual intervention?

Answers:

- Runbook
- Orchestration
- Response
- ***Playbook**

Explanation:

Playbooks are linear checklists of required steps and actions that are to be taken to respond to an alert. While playbooks do support automated actions, they are often used to document the processes and procedures that are to be used by a human during a manual intervention.

Runbooks consist of a series of conditional steps to perform actions, such as sending notifications or threat containment. They are not used to document the processes and procedures that are to be used by a human during a manual intervention.

The orchestration component of the security orchestration, automation, and response (SOAR) system is responsible for gathering data and information from across the network. This is not used to document the processes and procedures that are to be used by a human during a manual intervention.

The response component of a SOAR system allows the system to automatically take actions against threats. It is not used to document the processes and procedures used by a human during a manual intervention.

q_siem_soar_retention_policy_secp8

As a cybersecurity analyst, you are tasked with managing the organization's security information and event management (SIEM) system. The system is experiencing performance degradation due to the volume of historical log and network traffic data.

What should you implement to manage the storage of this data effectively without compromising the system's performance?

Answers:

- Data compression techniques to reduce the size of the stored data.
- ***A retention policy to keep historical log and network traffic data for a defined period.**
- Increase the storage capacity of the SIEM system.
- Implement a data deletion policy to remove old data.

Explanation:

A retention policy to keep historical log and network traffic data for a defined period is the correct answer. A retention policy defines how long data should be kept based on its age, type, and relevance. This ensures that only necessary data is stored, improving system performance without compromising the ability to conduct retrospective incident and threat hunting.

While data compression techniques to reduce the size of the stored data can help to some extent, it does not address the root cause of the problem, which is the volume of data being stored. Additionally, compressed data may need to be decompressed for analysis, which can be time-consuming.

While increasing the storage capacity of the SIEM system might provide temporary relief, it does not address the underlying issue of managing the volume of data being stored. It could also lead to increased costs and further performance issues down the line.

While deleting old data can free up storage space, it may also remove valuable historical data that could be useful for future analysis or investigations. A retention policy is a more balanced approach that considers both storage limitations and the value of historical data.

q_siem_soar_security_logs_secp8

A technology firm's network security specialist notices a sudden increase in unidentified activities on the firm's security event and incident management (SIEM) incident tracking system.

An unknown entity or process also increases the number of reported incidents. The specialist decides to investigate these incidents.

Which combination of data sources would provide a balanced perspective to support the investigation?

Answers:

- ***System-specific security logs, which track system-level operations; logs generated by applications running on hosts; and real-time reports from the SIEM solution, summarizing incidents.**
- Gateway logs, which track incoming and outgoing network traffic; network interactions monitored by intrusion detection systems (IDS), which detect unauthorized activities; and logs from server OS components.
- User activity logs, which record user behaviors; daily summary reports from the SIEM solution; and high-level network overviews, providing a broad view of network activities.
- Logs from vulnerability assessment tools, which identify potential weaknesses; transaction logs from databases, tracking changes; and logs from mobile devices, recording device activities.

Explanation:

Security logs from specific systems and third-party applications provide insights into system and application operations. Real-time threat intelligence feeds from the SIEM solution to summarize incidents. Together, these sources offer a thorough view of in-depth investigations.

Gateway logs and intrusion detection system (IDS)-monitored interactions offer in-depth views of network activities, and virtualized server operating system (OS) logs provide server insights. However, this combination overlooks specific applications.

User activity logs focus on user behaviors, and daily summary reports and high-level network overviews need more granularity and depth for an exhaustive investigation.

Logs from host-based vulnerability assessment tools, database transaction logs, and mobile device logs would miss broader system and network-level activities required to understand the incidents.

q_siem_soar_soar_secp8

Which of the following systems is able to respond to low-level security events without human assistance?

Answers:

- SIEM
- IDS
- ***SOAR**
- Firewall

Explanation:

Security orchestration, automation, and response (SOAR) systems gather and analyze data like SIEM systems, but they take the analysis to the next level. SOAR is a solution stack of compatible software programs that allow an organization to collect data about security threats from multiple sources and respond to low-level security events without human assistance.

Security information and event management (SIEM) tools work by gathering different types of network information and data. This information is moved to one central place. SIEM systems are great tools that help network administrators filter data and improve security monitoring. Still, all alerts require manual intervention.

Intrusion detection systems (IDSs) can trigger alerts, but these systems do not respond to security threats on their own.

A firewall blocks traffic based on the configuration setup. However, firewalls do not respond to security threats on their own.

q_siem_soar_trend_reporting_secp8

You are a cybersecurity analyst working in a large organization that uses a security information and event management (SIEM) system.

The executive team has requested a report to help them understand the organization's security posture and make strategic decisions.

Which type of SIEM reporting metric would be MOST appropriate to use in this situation?

Answers:

- Authentication data, such as failed login attempts, and critical file audit data.
- Hosts with missing patches and/or configuration vulnerabilities.
- Privileged user account anomalies, such as out-of-hours use or excessive requests for elevated permissions.
- ***Trend reporting to show changes to key metrics over time.**

Explanation:

Trend reporting to show changes to key metrics over time is the correct answer. This type of reporting provides a high-level view of how the organization's security posture has evolved over time, which can help the executive team make strategic decisions. It can highlight patterns, show progress, and identify areas where further investment may be needed.

Authentication data, such as failed login attempts, and critical file audit data is important for operational security and immediate incident response, but it may not provide the strategic insight the executive team needs for long-term planning.

While hosts with missing patches and/or configuration vulnerabilities information is crucial for maintaining system security, it is more operational in nature and may not provide the high-level view required by the executive team.

Privileged user account anomalies, such as out-of-hours use or excessive requests for elevated permissions is a key metric for identifying potential insider threats or compromised accounts, but it is more focused on specific incidents rather than overall trends.

q_dlp_alert_only_secp8

You are the IT security manager at a mid-sized technology company. Your company uses a data loss prevention (DLP) system to protect sensitive data.

A senior developer, working on a critical project, attempts to copy a file containing non-confidential project code to a personal USB drive for working off-site. The DLP system detects this action as a violation of the company's data protection policy.

As the IT security manager, which DLP remediation action would you recommend to ensure the right balance between data protection and business continuity?

Answers:

- ***Alert only**
- Block
- Quarantine
- Tombstone

Explanation:

Alert only is the correct answer. This option would allow the copying of the file but would record the incident and possibly alert an administrator. Given that the file does not contain confidential information and the developer's role and need for off-site work, this option maintains business continuity while also keeping a record of the policy violation. This is the most appropriate solution in this context.

Block would prevent the user from copying the file while retaining their access to it. This could disrupt the developer's work and delay the critical project, which is not ideal given the non-confidential nature of the data.

Quarantine would deny the user access to the original file, possibly by encrypting it or moving it to a quarantine area in the file system. This is an excessive measure for non-confidential data and could significantly disrupt the developer's work and the project timeline.

Tombstone would quarantine the original file and replace it with a file describing the policy violation and how the user can re-release it. This is an extreme measure for a file that does not contain confidential data and could cause unnecessary delays and complications for the developer and the project.

q_dlp_dlp_secp8

Which of the following is a technology that tries to detect and stop sensitive data breaches, or data leakage incidents, in an organization?

Answers:

- ***Data loss prevention**
- Data transmission security
- Data hashing
- Public key cryptography

Explanation:

Data loss prevention (DLP) is a technology that tries to detect and stop sensitive data breaches, or data leakage incidents, in an organization. DLP is used to prevent sensitive data from being disclosed to an unauthorized person, whether it is deliberate or accidental.

Data transmission security is the use of secure protocols to encrypt data when it is transmitted.

Hashing takes a variable-length string (message) and compresses and transforms it into a fixed-length value. When received, a hash is decrypted into the actual output so the recipient can understand the message.

Public key cryptography infrastructure uses certificates, which are electronic documents that use a digital signature, to bind a public key with an identity.

q_dlp_end_dlp_secp8

Which of the following DLP implementations can be used to monitor and control access to physical devices on workstations or servers?

Answers:

- Network DLP
- ***Endpoint DLP**

- File-level DLP
- Cloud DLP

Explanation:

Endpoint data loss prevention (DLP) runs on end user workstations and servers. Endpoint DLP is also referred to as a Chinese Wall solution. This could be something as simple as restricting the use of USB devices. Many endpoint-based systems also provide application controls to prevent confidential information transmission and also provide some type of immediate feedback to the user. Giving feedback to the user is based on the concept that not all data leakage incidents are malicious. The employee might not realize that the security-policy violation is inappropriate. The intent is to deter the employee from a similar action in the future.

The following types of DLP are not designed to monitor and control access to physical devices on workstations or servers:

- Network DLP tracks and analyzes the organization's network activity and traffic, across a traditional network and the cloud; this includes monitoring e-mail, messaging and file transfers, to detect when business critical data is being sent in violation of the organization's information security policies.
- File-level DLP monitors, detects and blocks sensitive data from leaving an organization.
- Cloud DLP is designed to help you discover, classify, and protect your most sensitive data..

q_dlp_net_dlp_secp8

DLP can be implemented as a software or hardware solution that analyzes traffic in an attempt to detect sensitive data that is being transmitted in violation of an organization's security policies.

Which of the following DLP implementations analyzes traffic for data containing such things as financial documents, social security numbers, or key words used in proprietary intellectual property?

Answers:

- ***Network DLP**
- Endpoint DLP
- File-level DLP
- Cloud DLP

Explanation:

Network DLP is a software or hardware solution that is typically installed near the network perimeter. Network DLP analyzes network traffic in an attempt to detect sensitive data that is being transmitted in violation of an organization's security policies.

The following types of DLP are not designed to analyze network traffic in an attempt to detect sensitive data that is being transmitted in violation of an organization's security policies:

- Endpoint data loss prevention (DLP) runs on end user workstations and servers, not across the network.
- File-level DLP monitors, detects and blocks sensitive data from leaving an organization from individual servers or workstations.
- Cloud DLP is designed to help you discover, classify, and protect your most sensitive data.

q_dlp_tombstone_secp8

You are the IT security manager at a large corporation. Your company uses a data loss prevention (DLP) system to protect sensitive data.

An employee attempts to copy a file containing confidential client information to a personal USB drive. The DLP system detects this action as a violation of the company's data protection policy.

As the IT security manager, which DLP remediation action would you recommend to ensure the highest level of data protection while maintaining a record of the policy violation?

Answers:

- Alert only
- Block
- Quarantine
- ***Tombstone**

Explanation:

Tombstone is the correct answer. This option would quarantine the original file and replace it with a file describing the policy violation and how the user can re-release it. This not only prevents the user from accessing the sensitive data but also provides a clear record of the policy violation and a process for the user to regain access to the file. This is the most comprehensive solution and provides the highest level of data protection.

Alert only would allow the copying of the file but would record the incident and possibly alert an administrator. While this maintains a record of the policy violation, it does not prevent the data from being copied, which could lead to a data breach.

Block would prevent the user from copying the file while retaining their access to it. While this stops the immediate data breach, the user still has access to the file and could attempt to copy it again or find another way to extract the data.

Quarantine would deny the user access to the original file, possibly by encrypting it or moving it to a quarantine area in the file system. While this prevents the user from accessing the file, it does not provide a clear record of the policy violation.

7.4 Penetration Testing

As you study this section, answer the following questions:

- What is the purpose of a penetration test?
- What are the different types of penetration tests?
- What is the role of the purple team?
- Which document defines what is included in the penetration test?
- What is the final phase in the penetration testing life cycle?

In this section, you will learn to:

- Explain the types of penetration testing tools.

The key terms for this section include:

Term	Definition
White box test	Penetration test in which the ethical hacker is given full knowledge of the target or network. This test allows for a comprehensive and thorough test, but is not very realistic.

Black box test	Penetration test in which the ethical hacker has no information regarding the target or network. This type of test best simulates an outside attack and ignores the insider threats.
Gray box test	Penetration test in which the ethical hacker is given partial information of the target or network, such as IP configurations, email lists, etc. This test simulates the insider threat.
Bug bounty	These unique tests are setup by organizations such as Google, Facebook, and others. Ethical hackers can receive compensation by reporting bugs and vulnerabilities they discover.
Scope of work	A very detailed document that defines exactly what is going to be included in the penetration test. This document is also referred to as the statement of work.
Rules of engagement	A document that defines exactly how the penetration test will be carried out.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	2.2 Explain common threat vectors and attack surfaces.
	• Human vectors/social engineering
	4.3 Explain various activities associated with vulnerability management.
	• Identification methods
	  ○ Open-source intelligence (OSINT)
	• Penetration testing
	  ○ Bug bounty program
	4.4 Explain security alerting and monitoring concepts and tools.
	• Tools
	  ○ Vulnerability scanners
	5.3 Explain the processes associated with third-party risk assessment and management.
	• Agreement types
	  ○ Work order (WO)/statement of work (SOW)
	• Rules of engagement
	5.5 Explain types and purposes of audits and assessments.
	• Penetration testing
	  ○ Physical

	○ Offensive ○ Defensive ○ Integrated ○ Known environment ○ Partially known environment ○ Unknown environment ○ Reconnaissance ▪ Passive ▪ Active
TestOut Security Pro	5.2 Assessment techniques 5.2.3 Scan for vulnerabilities

7.4.1 Penetration Testing (Lesson Video)

Transcript:

Penetration testing, often referred to as "pen testing," is a practice conducted to assess the security of an IT infrastructure by safely attempting to exploit vulnerabilities. These vulnerabilities may exist in operating systems, services and application flaws, improper configurations, or risky end-user behavior. The goal of this simulated attack on a system is to identify any weak spots in an organization's defense that attackers could potentially exploit. It's designed to provide organizations with valuable insights regarding their security posture and ability to withstand cyber attacks.

Once it has been decided what exactly can be tested, a timeframe and payment agreements—if applicable— should also be established and outlined in the Scope of Work. While the Scope of Work defines what work will be done, the Rules of Engagement define exactly how that work will be carried out. It should specifically state how sensitive data should be handled and who should be notified if something unexpected happens during the test. It should also specify what test methods should be used.
In penetration testing, we distinguish between two primary testing methods: active and passive. Active Penetration Testing involves direct interaction with the system to uncover vulnerabilities. This could be attempting to exploit a known software vulnerability or trying to crack a weak password. In this method, the tester is directly engaging with the target system, often leaving a trace or log of their activities. The main goal of active penetration testing is to breach the system's defenses and evaluate the impact of such a breach.
Passive Penetration Testing, on the other hand, involves gathering information about the target system without directly interacting with it. This could involve network monitoring, analyzing system logs, or even something as simple as googling for information about the system or the organization. The goal here is to gather as much information as possible to understand the system and identify potential vulnerabilities.
Passive testing is more covert, making it less likely to be noticed and, therefore, less likely to raise any alarms.
Both methods are usually used and are important for a comprehensive penetration test because both active and passive testing methods offer unique perspectives and insights into an organization's security posture.
A pen test might involve the following steps: First, verify that a threat exists. To do so, you'd use surveillance, social engineering, network scanners, and vulnerability assessment tools to identify weak spots where vulnerabilities could be exploited.
Next is to bypass security controls. This involves looking for easy ways to attack the system. Sometimes, the simpler solutions are the most vulnerable. For example, could the network firewall be bypassed by gaining physical access to the computer in the building? Once the computer has been accessed, malware could be introduced using a USB drive.
The next step is to actively probe controls for configuration weaknesses and errors. This could include weak passwords or software vulnerabilities. Finally, once vulnerabilities have been discovered, a pen tester will prove that a vulnerability is a high risk by exploiting it to gain access to data or to install backdoors.

That's it for this lesson. In this lesson, we talked about penetration testing. We discussed outlining and documenting the goals of the pen tests before testing begins, including specifications regarding whether tests will be active or passive. We then discussed the steps that are taken during a penetration test.

7.4.2 Penetration Testing Facts

Penetration testing, also commonly referred to as pentesting or ethical hacking, is the authorized simulation of an attack against an organization's security infrastructure. This can include physical and network security.

This lesson covers the following topics:

- Types of penetration tests
- Security teams
- Documentation/contracts
- Penetration testing life cycle

Types of Penetration Tests

The purpose of a penetration test is to discover any vulnerability in an organization's network or physical security. Different types of penetration tests can be performed to simulate internal or external threats. The following table details the types of penetration tests:

Penetration Test Type	Description
Known environment (previously known as white box) testing	The penetration tester is given full knowledge of the target or network. This test allows for a comprehensive and thorough test but is unrealistic.
Unknown environment (previously known as black box) testing	The penetration tester has no information regarding the target or network. This type of test best simulates an outside attack and ignores insider threats.
Partially known environment (previously known as gray box) testing	The penetration tester is given partial information about the target or network, such as IP configurations, email lists, etc. This test simulates the insider threat.
Bug bounties	These unique tests are programs that are set up by organizations such as Google, Facebook, and many others. The organization sets strict guidelines and boundaries for ethical hackers to operate within. Any discovered vulnerabilities are reported, and the ethical hacker is paid based on the severity of the vulnerability.

Security Teams

Depending on their role, members of security operations can be placed on different teams. These teams all work together to discover and fix security vulnerabilities.
The following table describes the more common security teams:

Security Team	Description
Red team	The red team members are the ethical hackers. This team is responsible for performing the penetration tests.
Blue team	Blue team members are the defense of the system. This team is responsible for stopping the red team's advances.
Purple team	Members of the purple team work on both offense and defense. This team is a combination of the red and blue teams.
White team	The white team members are the referees of cybersecurity. This team is responsible for managing the engagement between the red and blue teams. This group typically consists of the managers or team leads.

Documentation/Contracts

Before any penetration test can take place, the goals and guidelines of the test must be established. These are spelled out in the scope of work and rules of engagement documents.
The following table describes these important documents:

Document Type	Description
Scope of work	The scope of work is a very detailed document that defines exactly what is going to be included in the penetration test. This document is also referred to as the statement of work. This document should answer the: • Who - specific IP ranges, servers, applications, etc., should be explicitly listed. • What - anything that is off limits, such as specific servers or tactics, should be explicitly listed. • When - the time frame for the penetration test. This should identify how long the test will run, the deliverables, and when the deliverables are due. • Where - the location of the penetration tester. Sometimes, the penetration tester will be located in a different state. In this case, all parties must agree on which state laws will be followed. • Why - the purpose and goals of the test. Penetration tests are often performed for compliance purposes, and these requirements must be detailed in the document. Special considerations, such as travel, required certifications, or anything else unexpected, will be defined in the scope of work. Finally, the scope of work should define payment and how to handle requests for additional work. This will help to reduce scope creep.
Rules of engagement	The rules of engagement document defines exactly how the penetration test will be carried out. The following should be defined in the rules of engagement: • Type of test - whether the test will be a white box, black box, or gray box test.

Document Type	Description
	• Data handling - an explicit statement of how sensitive data is to be handled. Be aware that the pentester will typically come across sensitive data during a penetration test. • Notifications - the detailed process on when and how to notify the IT team.

Penetration Testing Life Cycle

Once the paperwork is complete, the pentester can begin work. The following table covers the phases of the penetration testing life cycle:

Penetration Testing Life Cycle Phase	Description
Perform reconnaissance	The first phase in the pentesting process is reconnaissance, also known as footprinting. In this phase, the pentester begins gathering information on the target. This can include gathering publicly available information, using social engineering techniques, or even dumpster diving.
Scan/enumerate	Running scans on the target is the second phase. During this phase, the ethical hacker is actively engaged with the target. Enumeration is part of the scanning phase. Enumeration uses scanning techniques to extract information, such as: • Usernames • Computer names • Network resources • Share names • Running services
Gain access	The third phase takes all of the information gathered in the reconnaissance and scanning phases to exploit any discovered vulnerabilities in order to gain access. After gaining access, the pentester can perform lateral moves, pivoting to other machines on the network. The pentester will begin trying to escalate privileges with the goal of gaining administrator access.
Maintain access	Once the pentester has gained access, maintaining that access becomes the next priority. This can be done by installing backdoors, rootkits, or Trojans.
Report	The final phase is generating the test results and supporting documentation. After any penetration test, a detailed report must be compiled. Documentation provides extremely important protection for both the penetration tester and the organization.

7.4.3 Penetration Testing Methods

This lesson covers the following topics:

- Penetration tests
- Active and passive reconnaissance
- Known, partially known, and unknown testing methods
- Exercise types

Penetration Tests

A penetration test—often shortened to pen test—uses authorized hacking techniques to discover exploitable weaknesses in the target's security systems. Pen testing is also referred to as ethical hacking. A pen test might involve the following steps:

- Verify a Threat Exists — use surveillance, social engineering, network scanners, and vulnerability assessment tools to identify a vector by which vulnerabilities could be exploited.
- Bypass Security Controls — look for easy ways to attack the system. For example, if the network is strongly protected by a firewall, is it possible to gain physical access to a computer in the building and run malware from a USB stick?
- Actively Test Security Controls — probe controls for configuration weaknesses and errors, such as weak passwords or software vulnerabilities.
- Exploit Vulnerabilities — prove a vulnerability is a high risk by exploiting it to access data or install backdoors.

The critical difference from passive vulnerability assessment is that an attempt is made to actively test security controls and exploit any vulnerabilities discovered. Pen testing is an intrusive assessment technique. For example, a vulnerability scan may reveal that an SQL Server has not been patched to safeguard against a known exploit. A penetration test would attempt to use the exploit to perform code injection and compromise the server. This provides active testing of security controls.

Active and Passive Reconnaissance

Active and passive reconnaissance provides crucial information that helps penetration testers understand target systems and identify potential vulnerabilities to plan an attack effectively. A combination of active and passive reconnaissance techniques yields the most comprehensive information regarding the target environment during a penetration testing engagement.

Active reconnaissance involves probing and interacting with target systems and networks to gather information. Active reconnaissance includes activities that generate network traffic by directly requesting information from target systems. Active reconnaissance aims to discover and obtain information about the target infrastructure, services, and potential vulnerabilities. Standard techniques used in active reconnaissance include the following:

- Port Scanning — scanning a target network to identify open ports and their services.
- Service Enumeration — interacting with identified services to gather information about their versions, configurations, and potential vulnerabilities.
- OS Fingerprinting — attempting to identify the operating system running on target machines by analyzing network responses and behavior.
- DNS Enumeration — gathering information about the target's DNS infrastructure, such as domain names, subdomains, and IP addresses.
- Web Application Crawling — exploring web applications to identify pages, directories, and potential vulnerabilities.
- Open-Source Intelligence (OSINT) Gathering — collecting publicly available information from various sources like search engines, social media, public databases, and websites.
- Network Traffic Analysis — monitoring network traffic to identify patterns, devices, IP addresses, and potential vulnerabilities without actively generating traffic.
- Social Engineering — gathering information through social engineering techniques, such as deceiving employees and vendors to extract sensitive information or access credentials.

Passive reconnaissance helps penetration testers gather initial information on a target's digital footprint. It is less intrusive and has a lower detection risk than active reconnaissance techniques.

Known, Partially Known, and Unknown Testing Methods

The decision to use a known environment, partially known environment, or unknown environment penetration test is influenced by several factors, such as knowledge regarding the target system or network, the organization's risk appetite, and compliance requirements. Budget and resource constraints may also contribute to selecting the penetration testing method, as known environment testing generally requires fewer resources than partially known or unknown environment testing. The objectives of the penetration test influence the choice, with known environment testing suitable for assessing known vulnerabilities and partially known or unknown environment testing preferred for identifying unknown vulnerabilities. The complexity of the target system or network is also a factor, as more complex systems may necessitate more comprehensive testing methods. Organizations often combine different methods to achieve other objectives.

Exercise Types

Penetration testing is a crucial component of cybersecurity assessments that involves simulating real-world attacks on computer systems, networks, or applications to identify vulnerabilities and weaknesses. Different types of penetration tests exist to address specific objectives related to a security evaluation, such as testing specific systems, assessing incident response capabilities, measuring the effectiveness of physical controls, and many other areas. Different types of penetration tests allow organizations to use a flexible and prioritized approach toward security assessment.

- Physical penetration testing, or physical security testing, describes assessments of an organization's physical security practices and controls. It involves simulating real-world attack scenarios to identify vulnerabilities and weaknesses in physical security systems, such as access controls, surveillance, and perimeter defenses. Physical penetration testing aims to assess the effectiveness of physical security controls and identify potential entry points or weaknesses that an attacker could exploit. During physical penetration testing, a skilled tester attempts to gain unauthorized physical access to restricted areas, sensitive information, or critical assets within the organization using techniques like social engineering, tailgating, lock picking, bypassing alarms or surveillance systems, and exploiting physical vulnerabilities.
- Integrated penetration testing refers to a holistic approach that combines different types of penetration testing methodologies and techniques to assess the overall security of an organization's systems, networks, applications, and physical infrastructure. Integrated penetration testing aims to provide a comprehensive and realistic evaluation of an organization's security operations. The importance of integrated penetration testing lies in its ability to accurately represent the organization's security posture and identify potential risks often overlooked when testing in isolated areas. For example, offensive and defensive penetration testing comprehensively assesses an organization's security posture. Offensive testing identifies vulnerabilities and weaknesses, while defensive testing evaluates the organization's ability to detect and respond to threats. By integrating both approaches, organizations can improve their security capabilities to better protect against different threats.

Continuous pen testing is a similar concept, which focuses on technical vulnerabilities and is often configured to leverage automation, especially for CI/CD environments. Review the following for more information:
https://informer.io/resources/continuous-penetration-testing

7.4.4 Exploring Penetration Testing Tools (Demo Video)

Transcript:

In this demonstration, we're going to look at penetration testing tools that you can use to evaluate the security of your network or a particular host on your network.

As you probably know, Linux is a very popular platform for testing network and host security. First, you need to choose a Linux distribution that you can use for penetration testing. A good place to start looking for those distributions is the DistroWatch website. Many of the Linux distributions here can be run as a live CD or installed on the hard drive. A live CD is an optical disc or a bootable USB drive that has the Linux operating system installed on it. It can also have many of the security tools you need to perform a penetration test.

Because it's installed on a USB drive or an optical disc, you can insert that into the computer and boot the system off the disc. When you do, you'll have a Linux operating system up and running with the tools you need for testing.

There are several advantages associated with testing this way. First, there's a wide variety of free penetration testing tools available for the Linux operating system, and if you're using a LiveCD, you don't have to install an operating system.

If you're booting off an optical disc, there's no way for malware or anything else to actually affect the files on the disc.

There are many different distributions available. You can see their names here. You can also see the purpose of the distribution listed over here. Since we're interested in security, let's go over here and look at this one.

The most popular and well-accepted distribution for security and penetration testing is Kali Linux. Let's go ahead and click on that and see what we can learn. It tells us where the home page is and a lot of other information. I have its home page open in another tab, up here. We can read a little bit more and see what tools are actually included on this distribution. I'm going to go to the Download page. I see the latest version right here, Kali Linux 64-Bit. Over here, I can see the checksum, or hash value.

Now, I already have a copy of Kali downloaded and ready to go. We'll get to that in a minute. But I want to go back to DistroWatch. I'll go back to the previous page. I just want to point out that there's another Linux distribution called Parrot Linux. Parrot is a distribution with a collection of various utilities that are popular with penetration testers and computer forensic professionals. Here's the link to the home page, but I already have a tab opened up. Down here, you can read more about the project and learn about the different tools. Now back to Linux.

My Kali Linux ISO image is downloaded, and I've booted it up. Now it's asking me now if I want to install it to disc or just use it as a LiveCD. I'll go ahead and say, "Sure, go ahead and just use it as a LiveCD."

We'll let it launch, and pretty soon, we'll see the graph called User Interface. Each Linux distribution has its own set of package tools. This one specializes in security tools.

Here are some of the tools that Kali Linux has packaged with its distribution. Over here, you'll see the Metasploit Framework Armitage (which is a graphical user interface for that framework), Burp Suite, BeEF Cross-Site Scripting Framework, and some others that we could use to do our penetration testing.

Now, obviously, we don't have time in this short video to really discuss penetration testing or even look at a specific tool in-depth, but I'll show you how you could penetration test using one of the pre-packaged tools that we can launch from a LiveCD.

Let's start the Metasploit Framework by clicking on it. That's going to create the database where we're going to save some of the information about hosts and other things. Once that's done, I'll go ahead and bring up Armitage, which is the graphical user interface that we can use to easily interact with the extensive commands that exist as part of the Metasploit framework.

It looks like that's launched now, and we'll go ahead and launch Armitage. There it is. We'll connect, and it asks us if we want to start the remote procedure called Server. We'll say, "Sure, that'll be great. It'll connect us up to the database." It takes just a minute to make those connections.

It looks like it made the connection, and it'll launch here shortly. We're greeted with several different windows and several different options. Essentially, what we need to do is tell Armitage (and, in conjunction, the Metasploit Framework) which hosts we want to actually try to launch an attack on. We could use an Nmap scan to import that information. We could also use the Metasploit Framework scan, which will go out and ping the different machines in a certain subnet and gather information.

In this case, I'm going to keep it simple so we don't scan all the hosts on our network, and I'll just add a single host, a vulnerable Linux virtual machine that I have on the network. I know it's on the IP ending in .102. Now click Add and then OK. It says that it added it, and we've identified a host. However, we don't have much information about it yet.

But if I right-click on that host, I can scan it. Now it'll look for all the open ports, and you can see a variety of open ports that are coming up. We can also request additional information about services that might be running and on specific ports.

So you can see here that we have certain ports, but we don't know much about the services quite yet.

If we wanted to, we could try to gather some additional information. Let's do an MSF scan on that host, and that will try to identify some information about the operating system that's running on it. You'll notice that every time we run a command it launches a separate window down here, so you could go along and close these out as you go.
We know some information about this computer--some of the ports that are open, some of the services that may be running, etc. It's not a lot of data, but Metasploit keeps track of the vulnerabilities based on the ports that are open, the services that are running, the operating system that's running, and so on. You can come up here, and you can actually find attacks specific to the host that you've already discovered. We'll let it go through its database and find specific exploits that it might want to try.
So, that's complete. Now we could go through the attack menu and look for a specific exploit. You'll see here that, based on the ports that it found, it said, "Hey, FTP's open. Go ahead and try these exploits."
Each of these exploits will run the specific exploit when you click on them, and you have to provide specific values for the exploit. We don't actually know if any of these attacks will run, so the ability to check on that is built into the Metasploit framework. Some of the exploits have the ability to use this check; others are older and don't.
Let's try doing a check on some of these right now. It says this one doesn't support the check, this specific vulnerability is not exploitable, not exploitable, doesn't support the check, and so on. For the ones that don't support the check, we'd have to go through and try each of them individually.
Now, generally, as you're looking at an organization and trying to compromise hosts within it, you don't want to make a lot of noise or cause a lot of traffic on the network, so you try these very specific attacks based on what you discover. However, there is an option inside of Armitage (and, subsequently, Metasploit) that lets you do what's known as the Hail Mary, and that is just try out every single attachment possible. In the interest of time, rather than going through every single one of these attacks in a systematic way, we'll do the noisy attack because I want to show you how you can compromise the mission, and we'll see which vulnerabilities actually exist.
If we click on Hail Mary here, then it says, "Hey, are you sure you want to do this? There's going to be a flood of exploits, and it's kind of noisy. We'll say yes, that's what we intend to do, and then it'll go through that database of exploits and try to run them with a variety of different payloads so that it's trying to establish a connection to that remote machine. We'll let it do its thing here for a minute.
It went through the database, and now it's launching each of those exploits. You'll see that the exploits are going to certain ports based on the services that are running on those. We'll give it another minute here, and it'll start taking advantage of some of those exploits.
Oh look, our icon changed. That means we actually have a connection. And once it made the connection, it gathered some additional information and says, "Yep, this is definitely a Linux box." We can see what version of Linux and some other information, too.
Once we have a session, we can gather all sorts of data. We can get the dump of the passwords and the hashes associated with the passwords and then try to crack those. Maybe we compromise the accounts and get more straightforward access, but there's all of these different sessions that we could establish based on the different exploits that we just ran. Again, usually, you wouldn't do the Hail Mary because it's too noisy. But in this case, it's a quick and easy demonstration of the vulnerabilities that exist on this specific machine.
If we scroll down here, we'll see a variety of exploits that exist for this machine, and we'll give ourselves a little bit more space. You can see, as we scroll up, that it looks like there's a PHP exploit, PHP CGI injection. There's a user map, a Samba exploit, another Samba exploit, and several others that actually allowed us to have a session over to that machine.
Let's go ahead and open a new console session. I'll adjust these windows so we can see better. We can run the sessions command, and you'll see that we currently have four sessions connecting from our machine. I know that's this IP address to this vulnerable machine, right there, through PHP, and then through some command lines.
Let me go ahead and connect to one of these sessions interactively. We'll choose Session 2, and now I've got a Linux command prompt. I can do things like list the file system. I can say, "Who am I?" If you look at the bottom here, I have root access. With that access, I could grab the hashes for the passwords. I could execute any commands. I could set up additional back doors. I could do all sorts of things.
Penetration testing is awesome, and ultimately, we're trying to compromise systems so that we know how to lock them down. To do that, we often use these pre-packaged tools that come with the distribution. Kali Linux along with Metasploit and Armitage already pre-packaged is a fantastic tool to use for penetration testing.
That's it for this demonstration. In this demo, we talked about penetration testing tools, and then we talked about the concept of a LiveCD and looked at a couple of Linux distributions that you could download and use in your testing.

7.4.5 Practice Questions (Section Quiz)

q_pene_test_access_secp8

Which step in the penetration testing life cycle is accomplished using rootkits or Trojan horse programs?

Answers:

- Gain access
- Reconnaissance
- ***Maintain access**
- Enumeration

Explanation:

Once a penetration tester has gained access, maintaining that access becomes the next priority. This can be done by installing backdoors, rootkits, or Trojans.

Gain access is the third phase of the penetration test life cycle and uses the information gathered in earlier phases to exploit discovered vulnerabilities.

Reconnaissance is the first phase in the penetration testing process. This is when the penetration tester begins gathering information.

Enumeration is the second phase in the penetration testing process. The penetration tester uses scanning techniques to extract information such as usernames and computer names.

q_pene_test_blue_01_secp8

You have been hired as part of the team that manages an organization's network defense.

Which security team are you working on?

Answers:

- Purple
- Red
- ***Blue**
- White

Explanation:

Blue team members are the defense of the system. This team is responsible for stopping the red team's advances.

Members of the purple team work on both offense and defense. This team is a combination of the red and blue teams.

The red team members are the ethical hackers. This team is responsible for performing the penetration tests.

The white team members are the referees of cybersecurity. This team is responsible for managing the engagement between the red and blue teams. This group typically consists of the managers or team leads.

q_pene_test_blue_02_secp8

A recent attack on the company involving a threat actor from another country prompted the security team to host regular penetration testing exercises.

The attack involved the IT team and human resources because the breach occurred on an employee desktop.

In the upcoming training, what role would the human resource team portray along with the IT team to simulate the recent attack and its experiences?

Answers:

- ***Blue team**
- Purple team
- White team
- Red team

Explanation:

The blue team is one of two competing teams in a penetration testing exercise. The blue team performs a defensive role by operating, monitoring, and alerting controls.

The purple team members act as facilitators during a purple team exercise. This type of exercise involves collaboration between red and blue teams during breaks throughout the training.

The white team is responsible for setting the engagement rules and monitoring the penetration testing exercise.

The red team is one of two competing teams in a penetration testing exercise. The red team performs the offensive role to try to infiltrate the target.

q_pene_test_bug_bounty_secp8

As part of a special program, you have discovered a vulnerability in an organization's website and reported it to the organization. Because of the severity, you are paid a good amount of money.

Which type of penetration test are you performing?

Answers:

- White box
- Black box
- Gray box
- ***Bug bounty**

Explanation:

Bug bounties are unique tests that are set up by organizations such as Google and Facebook. The organization sets strict guidelines and boundaries for ethical hackers to operate within. Discovered vulnerabilities are reported, and the ethical hacker is paid based on the severity of the vulnerability.

In a white box test, the ethical hacker is given full knowledge of the target or network. This test is comprehensive and thorough, but it is not very realistic.

In a black box test, the ethical hacker has no information regarding the target or network. This type of test best simulates an outside attack and ignores insider threats.

In a gray box test, the ethical hacker is given partial information about the target or network, such as IP configurations and email lists. This test simulates an insider threat.

q_pene_test_recon_secp8

Which phase or step of a security assessment is a passive activity?

Answers:

- Enumeration
- ***Reconnaissance**
- Privilege escalation
- Vulnerability mapping

Explanation:

Reconnaissance is the only step of a security assessment (penetration test) that is passive.

Enumeration, vulnerability mapping, and privilege escalation are all active events in a security assessment.

q_pene_test_red_secp8

Which team performs the offensive role in a penetration exercise?

Answers:

- ***Red team**
- Blue team
- White team
- Purple team

Explanation:

The red team performs the offensive role to try to infiltrate the target. This team is one of two competing teams in a penetration testing exercise.

The blue team performs a defensive role by operating, monitoring, and alerting controls. This team is one of two competing teams in a penetration testing exercise.

The white team is responsible for setting the engagement rules and monitoring the penetration testing exercise.

The purple team members act as facilitators during a purple team exercise. This type of exercise involves collaboration between red and blue teams during breaks throughout the training.

q_pene_test_roe_01_secp8

The IT security team at a large company is reviewing its security practices to improve resilience against cyber threats. The team wants to assess the network's vulnerability to potential attacks.

The IT team decides to conduct a penetration testing exercise and hires an external cybersecurity firm with expertise in penetration testing. The goal is to identify security weaknesses and gaps that malicious actors could exploit. The company also ensures that the proper rules of engagement (ROE) are in place for the testing.

What is the primary purpose of having ROE in a penetration testing exercise?

Answers:

- ***To define the scope, limitations, and legal boundaries of the testing.**
- To determine the specific vulnerabilities present in the network.
- To identify the external cybersecurity firm responsible for conducting the test.
- To ensure the cybersecurity firm uses specialized tools for the testing.

Explanation:

ROE is essential in penetration testing exercises since it defines specific objectives, scope, limitations, and legal testing boundaries. ROE helps prevent unauthorized actions and ensures the testing remains within legal and ethical boundaries.

Penetration testing identifies specific vulnerabilities in the network. This is not the primary purpose of having ROE.

The presence of ROE does not concern identifying the external cybersecurity firm responsible for conducting the penetration test.

Specialized tools for testing are an important aspect of conducting a penetration test, but it is not the primary purpose of having ROE.

q_pene_test_roe_02_secp8

In a cybersecurity firm, the IT department is preparing for a penetration testing engagement to assess the organization's security posture. The team has decided to conduct an external penetration test on the company's public-facing web applications and networks.

The primary goal is to identify vulnerabilities and potential entry points for attackers. To ensure a smooth testing process and avoid misunderstandings, the IT team has collaborated with the company's management and relevant stakeholders to establish the assessment's rules of engagement (ROE).

What is the purpose of establishing ROE in a penetration testing engagement?

Answers:

- ***To define the scope of the assessment, testing methods, and timeframe for conducting the test.**
- To ensure the penetration test results are shared with external parties to strengthen collaboration.
- To allow penetration testers unrestricted access to all systems and data within the organization.
- To eliminate all security vulnerabilities identified during the testing process.

Explanation:

Establishing rules of engagement (ROE) in a penetration testing engagement is essential to define the assessment's scope, testing methods, and timeframe. The IT team uses ROE to prevent unintended disruptions to critical services and ensure a smooth testing process.

Although collaboration with external parties is important, the primary purpose of ROE is to establish the parameters and scope of the testing.

During the penetration test, ROE imposes limitations on accessing certain resources to prevent unauthorized access to sensitive information or systems.

The main goal of penetration testing is to identify vulnerabilities, not eliminate them. The focus is on discovering weaknesses for remediation rather than fixing them during the assessment.

q_pene_test_roe_03_secp8

The IT department in an accounting firm is gearing up for an external penetration testing engagement to evaluate the organization's security readiness.

To guarantee a seamless testing process and prevent misunderstandings, the IT team has worked closely with the company's management and relevant stakeholders to set up the rules of engagement (ROE) for the assessment.

What is the purpose of establishing rules of engagement during a penetration testing engagement?

Answers:

- ***To define the scope of the assessment, testing methods, and timeframe for conducting the test.**
- To ensure the penetration test results are shared with external parties to strengthen collaboration.
- To allow penetration testers unrestricted access to all systems and data within the organization.
- To eliminate all security vulnerabilities identified during the testing process.

Explanation:

Establishing ROE in a penetration testing engagement is essential to define the assessment's scope, testing methods, and timeframe. The IT team uses ROE to prevent unintended disruptions to critical services and ensure a smooth testing process.

Although collaboration is important, the primary purpose of ROE is to establish the parameters and scope of the testing.

During the penetration test, ROE imposes limitations on accessing certain resources to prevent unauthorized access to sensitive information or systems.

The main goal of penetration testing is to identify vulnerabilities, not eliminate them. The focus is on discovering weaknesses for remediation rather than fixing them during the assessment.

q_pene_test_social_secp8

Which of the following activities are typically associated with a penetration test?

Answers:

- Interview employees to verify that the security policy is being followed.
- Run a vulnerability scanner on network servers.
- ***Attempt social engineering.**
- Create a performance baseline.

Explanation:

Penetration testing typically uses tools and methods that are available to attackers. Penetration testing might start with attempts at social engineering or other reconnaissance activities. This may be followed by more active scans of systems and actual attempts to access secure systems.

A vulnerability scanner checks a system for weaknesses. Vulnerability scanners typically require administrative access to a system and are performed internally. They are not done to test system security. Typically, penetration testers cannot run a vulnerability scanner unless they have gained authorized access to a system.

A performance baseline is created by an administrator to identify normal network and system performance. Auditing might include interviewing employees to make sure that security policies are being followed.

q_pene_test_sow_secp8

Which of the following is a very detailed document that defines exactly what will be included in the penetration test?

Answers:

- Rules of engagement
- ***Scope of work**
- Goals and guidelines
- Payment terms

Explanation:

A scope of work is a very detailed document that defines exactly what will be included in the penetration test. This document is also referred to as the statement of work.

The rules of engagement document defines exactly how a penetration test is to be carried out.

Goals and guidelines are not a document type. The scope of work and rules of engagement documents detail the goals and guidelines of a penetration test.

Payment terms are not a document type. Payment terms are defined in the scope of work document.

q_pene_test_testing_01_secp8

Which of the following uses hacking techniques to discover internal vulnerabilities proactively?

Answers:

- Reverse engineering
- ***Penetration testing**
- Inbound scanning
- Passive reconnaissance

Explanation:

Penetration testing is the practice of testing systems and policies proactively for vulnerabilities. This approach seeks to identify vulnerabilities internally before a malicious individual can take advantage of them. Common techniques are identical to those used by hackers and include network/target enumeration and port scanning.

q_pene_test_testing_02_secp8

What is the primary purpose of penetration testing?

Answers:

- ***To test the effectiveness of your security perimeter.**
- To evaluate newly deployed firewalls.
- To assess the skill level of new IT security staff.
- To infiltrate a competitor's network.

Explanation:

The primary purpose of penetration testing is to test the effectiveness of your security perimeter. Only by attempting to break into your own secured network can you be assured that your security policy, security mechanism implementations, and deployed countermeasures are effective. It is important to obtain senior management's approval before starting a penetration test or vulnerability scanning project. Often, penetration testing or vulnerability scanning is performed by an external consultant or security outsourcing agency hired by your organization.

q_pene_test_white_box_secp8

You have been hired to perform a penetration test for an organization. You are given full knowledge of the network before the test begins.

Which type of penetration test are you performing?

Answers:

- ***White box**
- Black box
- Gray box
- Bug bounty

Explanation:

In a white box test, the ethical hacker is given full knowledge of the target or network. This test allows for a comprehensive and thorough test, but it is not very realistic.

In a black box test, the ethical hacker has no information regarding the target or network. This type of test best simulates an outside attack and ignores insider threats.

In a gray box test, the ethical hacker is given partial information about the target or network, such as IP configurations, email, and lists. This test simulates an insider threat.

Bug bounties are unique tests that are set up by organizations such as Google and Facebook. The organization sets strict guidelines and boundaries for ethical hackers to operate within. Any discovered vulnerabilities are reported, and the ethical hacker is paid based on the severity of the vulnerability.

q_pene_test_white_secp8

You have been promoted to team lead of one of the security operations teams.

Which security team are you now a part of?

Answers:

- Purple
- Red
- Blue
- ***White**

Explanation:

The white team members are the referees of cybersecurity. This team is responsible for managing the engagement between the red and blue teams. This group typically consists of the managers or team leads.

Blue team members are the defense of the system. This team is responsible for stopping the red team's advances.

Members of the purple team work on both offense and defense. This team is a combination of the red and blue teams.

The red team members are the ethical hackers. This team is responsible for performing the penetration tests.

q_pentest_meth_active_reconnaissance_secp8

You are a cybersecurity specialist conducting an active reconnaissance as part of a penetration test for a client. Your goal is to gather as much information as possible about the client's network without raising any alarms.

Which of the following techniques would be MOST effective in achieving this goal?

Answers:

- Social engineering
- ***DNS enumeration**
- Network traffic analysis
- Physical intrusion

Explanation:

DNS enumeration is the correct answer. DNS enumeration involves gathering information about the client's DNS infrastructure, such as domain names, subdomains, and IP addresses. This technique is a part of active reconnaissance and can provide valuable information about the client's network without raising alarms.

While social engineering can be a powerful tool in a penetration tester's arsenal, it is not the best choice in this scenario. Social engineering involves manipulating individuals to reveal confidential information, which can be risky and potentially alert the client to your activities.

Network traffic analysis is typically considered a passive reconnaissance technique, not an active one. It involves monitoring network traffic to identify patterns, devices, IP addresses, and potential vulnerabilities without actively generating traffic.

Physical intrusion involves gaining unauthorized physical access to a location, which is not only illegal but also likely to raise alarms. It is not a part of active reconnaissance and is not the best choice in this scenario.

q_pentest_meth_defensive_secp8

A financial institution has hired a team of security professionals to evaluate its defensive security measures and incident response procedures.

The institution wants to assess how effectively it can detect and respond to cyber threats and identify areas for improvement. However, it is not looking for an assessment of the digital vulnerabilities or physical security at this time.

What type of penetration testing is the MOST suitable for this financial institution?

Answers:

- Offensive penetration testing
- ***Defensive penetration testing**
- Physical penetration testing
- Integrated penetration testing

Explanation:

Defensive penetration testing, or "blue teaming," assesses an organization's defensive security measures, detection capabilities, and incident response procedures. This method is the most suitable type of penetration testing for the financial institution, as it is specifically interested in evaluating its ability to detect and respond to cyber threats.

Offensive penetration testing, or "red teaming," involves simulating real-world cyberattacks on an organization's digital systems to identify vulnerabilities and weaknesses.

Physical penetration testing evaluates an organization's physical security practices and controls to identify potential entry points or weaknesses that an attacker could exploit.

Integrated penetration testing combines different types of penetration testing methodologies and techniques to evaluate an organization's security operations comprehensively.

q_pentest_meth_integrated_secp8

A multinational corporation hires a team of penetration testers to assess the security of its operations across both digital and physical domains.

The team incorporates a few penetration testing techniques, including simulating real-world cyberattacks, evaluating defensive measures, and assessing physical security controls.

What approach to penetration testing is the corporation using?

Answers:

- Offensive penetration testing
- Defensive penetration testing
- Physical penetration testing
- ***Integrated penetration testing**

Explanation:

Integrated penetration testing is a holistic approach that combines different types of penetration testing methodologies and techniques to assess the overall security of an organization's systems, networks, applications, and physical infrastructure.

Offensive penetration testing, or "red teaming," is a proactive approach to simulate real-world cyberattacks on an organization's systems, networks, and applications to identify vulnerabilities and weaknesses.

Defensive penetration testing, or "blue teaming," evaluates an organization's defensive security measures, detection capabilities, and overall resilience against cyber threats.

Physical penetration testing assesses an organization's physical security practices and controls. It involves simulating real-world attack scenarios to identify vulnerabilities and weaknesses in physical security systems.

q_pentest_meth_known_secp8

A cybersecurity team is preparing to conduct a comprehensive security assessment. The team has access to system documentation, network diagrams, and source code and has permission to interview IT staff.

What type of testing environment is the team operating within?

Answers:

- ***Known environment**
- Partially known environment
- Unknown environment
- Uncontrolled environment

Explanation:

A known environment refers to situations where the testers have complete information about the system's internals, design, infrastructure, and security measures.

A partially known environment refers to situations where the tester only has limited information about the system. However, in this scenario, the team has full access to detailed system information, going beyond what would typically be available in a partially known environment.

The tester has little to no information about the system in an unknown environment. Given the extensive information available to the team in this scenario, this environment is still unknown.

An uncontrolled environment is not a standard term used in system testing.

q_pentest_meth_offensive_secp8

A cybersecurity team at an organization prepares to carry out an assessment that aims to mimic potential attackers' tactics, techniques, and procedures (TTPs) to identify vulnerabilities and weaknesses in the organization's digital systems.

What type of penetration test is the team about to conduct?

Answers:

- ***Offensive penetration testing**
- Defensive penetration testing
- Physical penetration testing
- Integrated penetration testing

Explanation:

Offensive penetration testing is a proactive and controlled approach to simulate real-world cyberattacks on an organization's systems, networks, and applications to identify vulnerabilities, weaknesses, and potential attack vectors that malicious actors could exploit.

Defensive penetration testing evaluates an organization's overall resilience against cyber threats, not actively trying to find vulnerabilities as an attacker might.

Physical penetration testing involves assessing an organization's physical security practices and controls, such as access controls, surveillance, and perimeter defenses.

While integrated penetration testing can include offensive penetration testing, the scenario specifically describes an offensive penetration test.

q_pentest_meth_partially_01_secp8

The IT security team of a company has concerns about network vulnerabilities and hires an external penetration tester to evaluate its security controls and identify potential risks.

The company provides the penetration tester with fragments of network information and permits them to use reconnaissance techniques for further information gathering.

What penetration testing method is the company using?

Answers:

- Known environment penetration testing
- ***Partially known environment penetration testing**
- Unknown environment penetration testing
- Open-source intelligence gathering

Explanation:

Partially known environment penetration testing involves the tester's limited knowledge about the target system or network. During the test, the tester may employ reconnaissance techniques to gather additional information about the target.

Known environment penetration testing involves the tester having detailed knowledge about the target system or network, including information about the network architecture, hardware and software configurations, system vulnerabilities, and users.

Unknown environment penetration testing involves the tester having little knowledge about the target system or network. This testing mimics a scenario where an attacker has no preexisting information about the target infrastructure.

Open-source intelligence gathering is a passive reconnaissance technique that collects publicly available information from various sources. It is not a penetration testing method.

q_pentest_meth_partially_02_secp8

A cybersecurity team is investigating a complex cyber threat landscape for a large financial institution. The team is aware of some potential threats due to previous encounters and security measures in place, but the evolving nature of the landscape presents new threats and challenges.

What type of cyber environment is the team dealing with?

Answers:

- ***Partially known environment**
- Reconnaissance
- Unknown environment
- Fully known environment

Explanation:

The cybersecurity team is aware of some threats but not all due to the evolving nature of the cyber landscape. This level of awareness suggests they're operating in a partially known environment.

Performing reconnaissance is a technique used by cybersecurity teams to learn more about their environment and potential threats. It doesn't describe the type of environment the team is operating in.

A fully unknown environment suggests that the cybersecurity team needs to gain prior knowledge of potential threats or challenges, which isn't true in this scenario.

A fully known environment suggests that the cybersecurity team has complete knowledge of all potential threats and challenges, which needs to be more accurate in this scenario.

q_pentest_meth_passive_reconnaissance_secp8

You are a cybersecurity analyst tasked with gathering information about a potential target for a penetration test. Your goal is to collect as much data as possible without alerting the target or leaving any trace of your activities.

Which reconnaissance technique would be MOST suitable for this task?

Answers:

- Active reconnaissance
- ***Passive reconnaissance**
- Social engineering
- Physical intrusion

Explanation:

Passive reconnaissance is the correct answer. Passive reconnaissance involves collecting information about a target without directly interacting with the target system or network. This can include activities like observing publicly available information, analyzing metadata, or monitoring network traffic. Passive reconnaissance is less likely to alert the target or leave traces of your activities, making it the most suitable technique for this task.

While active reconnaissance can provide valuable information about a target, it involves directly interacting with the target system or network. This can potentially alert the target to your activities or leave traces of your actions, making it less suitable for this task.

Social engineering involves manipulating individuals to reveal confidential information. While it can be effective, it also carries a risk of detection, especially if the individuals become suspicious. Therefore, it is not the most suitable technique for this task.

Physical intrusion involves gaining unauthorized physical access to a location, which is not only illegal but also likely to raise alarms. It is not a part of reconnaissance and is not suitable for this task.

q_pentest_meth_pen_test_steps_secp8

You are a cybersecurity analyst working for a large corporation. You have been tasked with conducting a penetration test to identify potential vulnerabilities in the company's network.

You have already completed the initial step of verifying that a threat exists.

What should be your next step in the penetration testing process?

Answers:

- Exploit vulnerabilities.
- ***Bypass security controls.**
- Actively test security controls.
- Report findings to management.

Explanation:

Bypass security controls is the correct answer. After verifying that a threat exists, the next step in the penetration testing process is to bypass security controls. This involves looking for easy ways to attack the system. For example, if the network is strongly protected by a firewall, is it possible to gain physical access to a computer in the building and run malware from a USB stick?

Exploit vulnerabilities is not the correct next step in the penetration testing process. Before exploiting vulnerabilities, you need to identify potential weaknesses in the security controls. This is done by bypassing the security controls and actively testing them.

While actively testing security controls is an important step in the penetration testing process, it is not the next step after verifying that a threat exists. Before you can actively test security controls, you need to bypass them to identify potential weaknesses.

Reporting findings to management is the final step in the penetration testing process, not the next step after verifying that a threat exists. Before you can report your findings, you need to bypass security controls, actively test them, and exploit any vulnerabilities you find.

q_pentest_meth_process_steps_secp8

You are a cybersecurity analyst at a large corporation and have been tasked with conducting a penetration test to identify potential vulnerabilities in the company's network.

You have just completed the reconnaissance phase and have identified a potential vulnerability in the company's SQL Server. What is your next step?

Answers:

- Immediately report the vulnerability to the company's management.
- Exploit the vulnerability to gain access to the server.
- ***Actively test the security controls around the vulnerability.**
- Bypass the security controls and gain physical access to a computer in the building.

Explanation:

Actively test the security controls around the vulnerability is the correct answer. After identifying a potential vulnerability, the next step in a penetration test is to actively test the security controls around it. This can involve probing for configuration weaknesses and errors, such as weak passwords or software vulnerabilities.

Immediately report the vulnerability to the company's management is not the correct next step in a penetration test. While it's important to keep management informed, the purpose of a penetration test is to actively test and exploit vulnerabilities to understand their potential impact. Reporting should be done after these steps have been completed.

Exploit the vulnerability to gain access to the server is not the correct next step. Before attempting to exploit a vulnerability, it's important to actively test the security controls around it. This can help identify any additional weaknesses or protections that may affect the exploitation process.

Bypass the security controls and gain physical access to a computer in the building is not the correct next step. While physical access can sometimes be a part of a penetration test, it's not the appropriate response in this scenario. The identified vulnerability is in the SQL Server, so the focus should be on testing and potentially exploiting this vulnerability.

q_pentest_meth_tester_secp8

A company hires a team of penetration testers to evaluate the security posture of its newly developed web application. After a comprehensive analysis, the testers submit their findings, detailing potential vulnerabilities.

The company's security officer reviews the report and contemplates the essential differences between how threat actors and penetration testers would exploit the identified vulnerabilities.

What distinct motive differentiates a professional penetration tester from a threat actor when it comes to exploiting vulnerabilities in a system?

Answers:

- Penetration testers aim to damage or disrupt the system.
- Threat actors provide a detailed report of their findings.
- ***Penetration testers work to identify vulnerabilities and improve system security.**
- Threat actors have permission to test the system.

Explanation:

Penetration testers are professionals who evaluate the security posture of systems and networks. Their main goal is to identify vulnerabilities and recommend solutions to bolster security.

Unlike malicious attackers (threat actors), penetration testers do not have a motive to cause harm or service disruption. Their primary objective is to discover vulnerabilities without causing damage.

While penetration testers provide a comprehensive report to the organization after their analysis, threat actors typically do not submit any findings, as their primary goal might be theft, disruption, or other malicious intent.

Threat actors do not have permission, and their actions are illegal. Conversely, penetration testers operate under explicit consent from the organization.

q_pentest_meth_testing_secp8

An organization considers a new third-party vendor to provide critical technology solutions. It is nearing the final stages of the vendor selection process and wants to ensure a robust assessment of the vendor's security practices and risk management capabilities.

Which method would be MOST suitable for the organization to gain an in-depth understanding of the vendor's internal security controls, identify potential vulnerabilities in its systems, and validate the effectiveness of its security measures?

Answers:

- Rely on the vendor's self-assessment report.
- Perform a supply chain analysis.
- ***Conduct a penetration test.**
- Request evidence of internal audits.

Explanation:

Penetration testing is a proactive and in-depth method of testing a vendor's defenses. It helps organizations discover potential vulnerabilities in the vendor's systems, networks, and applications that attackers could exploit.

Self-assessments can be biased and may not accurately disclose all potential risks or vulnerabilities.

While supply chain analysis is important, it mostly helps the company understand the risk associated with multiple entities within the organization's supply chain.

While internal audits are important for providing insight into a vendor's risk management and compliance, they might not provide a detailed understanding of specific security vulnerabilities in the vendor's systems the way a penetration test would.

q_pentest_meth_unknown_01_secp8

A software company has completed in-house testing and auditing and is bringing in an outside source to attempt to compromise the new software. The project head wants to ensure that the MOST realistic testing goes against the software.

What type of penetration testing will the outside source use on this new software?

Answers:

- ***Unknown environment**
- Known environment
- Partially known environment
- Environmental variables

Explanation:

In an unknown environment, the contractor has no information about the software and performs extensive reconnaissance to attempt an attack on the software as an external threat would.

Known environment, the contractor has all the information about the software and uses this to compromise the application. This process is an example of an insider threat to the software.

In a partially known environment test, the contractor has some information about the software but will still need to perform reconnaissance.

Environmental variables related to vulnerability analysis refer to the systems and software a company has currently in use. Age and diversity, as well as complexity, are all variables. This process is not a software test.

q_pentest_meth_unknown_02_secp8

A cybersecurity team is preparing to conduct a comprehensive security assessment. The team needs more detailed information about the system, including system documentation, network diagrams, source code, and permission to interview IT staff.

What type of testing environment is the team operating within?

Answers:

- ***Unknown environment**
- Known environment
- Partially known environment
- Uncontrolled environment

Explanation:

The tester needs more information about the system in an unknown environment. Given the lack of information available to the team in this scenario, this environment is applicable.

A known environment refers to situations where the testers have complete information about the system's internals, design, infrastructure, and security measures.

A partially known environment refers to situations where the tester only has limited information about the system. Since the team cannot access detailed system information, this could not be the environment.

An uncontrolled environment is not a standard term used in system testing or this scenario.

8.0 Network and Endpoint Security

8.1 Operating System Hardening

As you study this section, answer the following questions:

What is hardening? How does it benefit security?

How do you reduce the attack surface of a device?

Why should you install only software that you need?

What is a security baseline?

What is the difference between a hotfix and a patch? Why would you use one instead of the other?

In this section, you will learn to:

Harden an operating system.

Manage automatic updates.

Configure automatic updates.

Configure Microsoft Defender Firewall.

The key terms for this section include:

Term	Definition
Patches	A small unit of supplemental code meant to address either a security problem or a functionality flaw in a software package or operating system.
Patch management	Identifying, testing, and deploying OS and application updates. Patches are often classified as critical, security-critical, recommended, and optional.
Allow list	A security configuration where access is denied to any entity (software process, IP/domain, and so on) unless the entity appears on an allow list, also known as a whitelist.
Block list	A security configuration where access is generally permitted to a software process, IP/domain, or other subject unless it is listed as explicitly prohibited.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.4 Explain the importance of using appropriate cryptographic solutions Encryption Level Full-disk 2.2 Explain common threat vectors and attack surfaces Removable device 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Access control Application allow list Patching Encryption Monitoring Least privilege Configuration enforcement Decommissioning Hardening techniques Installation of endpoint protection Host-based firewall Disabling ports/protocols Default password changes Removal of unnecessary software 4.1 Given a scenario, apply common security techniques to computing resources. Secure baselines

	Establish Deploy Maintain Hardening targets Workstations 4.3 Explain various activities associated with vulnerability management. Vulnerability response and remediation Patching 4.5 Given a scenario, modify enterprise capabilities to enhance security. Operating system security Group Policy 4.6 Given a scenario, implement and maintain identity and access management. Provisioning/de-provisioning user accounts Access controls Least privilege Multifactor authentication 4.7 Explain the importance of automation and orchestration related to secure operations. Use cases of automation and scripting Security groups
TestOut Security Pro	1.1 Manage identity 1.1.1 Manage Windows local and domain users and groups 1.2 Harden authentication 1.2.5 Configure and link Group Policy Objects (GPO) 2.1 Harden physical access 2.1.3 Install and configure a firewall 3.1 Harden computer systems

	3.1.2 Configure anti-virus protection 3.1.4 Configure Windows Update 3.2 Implement application defenses 3.2.1 Implement an application allow list

8.1.1 Operating System Hardening (Lesson Video)

Transcript:

The main purpose of hardening an operating system is to eliminate as many security risks as possible.

If they're not implemented correctly, passwords can be an operating system vulnerability. To mitigate this issue, passwords should be complex. This means that they should be at least 12 characters long and include capital letters, numbers, and symbols.
In a high-security environment, passwords alone are just too vulnerable; multi-factor authentication is a must. Multi-Factor authentication uses two or more authentication factors, such as something you know, like a password or a pin; something you have, like a smart card; or something you are, like a retina scan.
Another hardening technique is to limit operating system exposure. To do this, you should first ensure that administrative privileges are only provided to system administrators. Next, system management should ensure that users are only given the rights and permissions required to do their jobs â€“ nothing more. This concept is called the principle of least privilege.
You should also ensure that only the software used by administrators and users is installed on your systems. Removing unnecessary software reduces the attack surface, giving hackers fewer chances to exploit a system.
For that reason, you should disable unnecessary or non-essential services. Unused services often aren't configured securely or configured at all. They're attractive to hackers, and sustained attacks can go unnoticed.
Examples of non-essential services are TFTP, Telnet, and SNMP. These are all clear text services.
DNS, ICMP, and NTP are essential protocols and services. If your system isn't a DNS server, you'll want to disable the DNS service. It's good to note that in Windows 10, some of these services are disabled by default, such as Telnet and TFTP.
Systems should also be protected with security software, such as antivirus, anti-spyware, anti-rootkit, and personal or client firewall software. When you use this type of security software, ensure that it comes from a trusted publisher and doesn't conflict with other programs in use.
Another aspect of hardening an operating system is to develop system baselines. A baseline is a standard applied to systems. It defines standards for configuration management, security policies, software and backup policies, and several other topics. Developing standard baselines helps ensure that an organization is working at peak efficiency and security base.
If baselines are appropriately configured and applied, it becomes fairly easy to detect systems that may be vulnerable since they're operating outside established standards. There are several types of baselines to consider.
A configuration baseline establishes the standard configuration for all systems. This baseline defines the default system configuration, including loaded software, enabled services, and domain connectivity. Further configuration and changes to the configuration can be achieved via Group Policies.
A security baseline defines the secure computing components, such as the security software used to protect individual systems, that are installed and configured on your workstations. Definition updates and changes are all configured and ready to go as part of the baseline. In addition, any enterprise hardware such as firewalls, gateways, and SPAM filters (and their configurations) are specified as part of this baseline.
A software & use baseline defines acceptable system use and supported software. Software managers can control a user's ability to employ software. This can also help administrators by keeping track of use licenses and, potentially, reduce expenditures by limiting the number of purchased software use licenses. It also helps define appropriate use policies by defining how to implement Group Policies to provide allowed services while preventing unauthorized use of disallowed services.
As a whole, baselines should be reviewed and modified to reflect the changes organizations make constantly. When new software or new versions of existing software are introduced, the baseline must be changed to reflect the

update. If security policies change, such as the frequency of password changes or password complexity requirements, the baseline must be updated again. Baselines are not static. They should be thought of as a guideline or practice to ensure the efficient and safe use of computer systems. Further, they should reduce the attack surface that threat actors can exploit to gain access to your system.

The last topic for this lesson is patch management. Patch management is the process of managing patches for all of your systems. A patch management system can provide centralized control. A common system is Microsoft's patch management product Windows Software Update Service, or WSUS for short.

Patch management activities include determining which patches are needed on your systems, applying the patches, and then auditing for the successful application of those patches. Before patches are applied, a small group of deployments is usually tested, especially for service packs. If a problem exists with the patch process, it's much easier to handle a small deployment than to face a system-wide crisis. This group is generally comprised of power users who know how to fix issues. They're given additional permissions and rights so they can continue working if something goes wrong with deployment.

Larger organizations may have a lab that represents the types of systems in use by users throughout the enterprise. Tests are conducted within the lab and verified before they're released to the general user community. A best practice is to create a system restore point before you patch systems just in case something goes wrong.

Now, sometimes, a patch is overkill, so we also have hot fixes to choose from. Hot fixes are quick fixes for problems. Usually, you don't install the hot fix unless you have the specific problem it's intended for. Hot fixes sometimes address a specific customer situation and may be distributed only to that customer. Hot fixes are also commonly used to address freshly discovered security holes.

A patch could also be a temporary quick fix. Generally, a manufacturer tests patches more than a hot fix, and patches are designed for wider deployment. Patches can include hot fixes that the manufacturers have thoroughly tested for mass deployment. Patches typically contain fixes for security holes and discovered system bugs. As an example, Microsoft releases security patches once per month.

Service packs are installable packages that include several patches from the same vendor for various applications. Service packs usually include patches and hot fixes that have been tested by the manufacturer for wide deployment. Before fully deploying the service pack, you'll usually let a small designated group test it to make sure it's fully compatible with your system. But if you have a specific issue, you may want to install a patch or a hot fix immediately.

That's it for this lesson. In this video, we talked about operating system hardening. First, we discussed the importance of using secure passwords, limiting administrative privileges, installing only needed, secure software, and removing non-essential services. Next, we discussed the role baselines play in keeping our systems secure. We ended this lesson by discussing the importance of applying the latest patches and service packs to your systems.

8.1.2 Hardening Facts

This lesson covers the following topics:

- Operating system security
- Workstations
- Installing endpoint protection
- Patch management
- OS hardening best practices
- Encryption techniques

Operating System Security

Operating system security encompasses many practices that aim to protect against unauthorized access, data breaches, malware infections, and other security threats. There are many considerations and requirements when securing an

operating system because operating systems are complicated and powerful software products operating at the core of all information systems. Many security concepts apply to operating system security, including access controls, authentication mechanisms, secure configurations, application security, secure coding, patch management, endpoint protection, user awareness training, and monitoring.

Hardening describes changing an operating system or application to make it operate securely. The need for hardening must be balanced against functional requirements and usability because hardening can often negatively impact how applications work or interoperate.

Best practice baselines play a critical role in device hardening by providing a standard set of guidelines or checklists for configuring devices securely. These baselines, often developed by cybersecurity experts or organizations, offer a starting point for systems administrators to ensure that devices are configured according to industry security standards. Many of the requirements can be applied automatically via a configuration baseline template. The essential principle is of least functionality; that a system should run only the protocols and services required by legitimate users and no more. This reduces the potential attack surface.

- Interfaces provide a connection to the network. Some machines may have more than one interface. For example, there may be wired and wireless interfaces or a modem interface. Some machines may come with a management network interface card. If any of these interfaces are not required, they should be explicitly disabled rather than simply left unused.

- Services provide a library of functions for different types of applications. Some services support local features of the OS and installed applications. Other services support remote connections from clients to server applications. Unused services should be disabled.

- Application service ports allow client software to connect to applications over a network. These should be disabled or blocked at a firewall if remote access is not required. Be aware that a server might be configured with a nonstandard port. For example, an HTTP server might be configured to use 8080 rather than 80. Conversely, malware may try to send nonstandard data over an open port. An intrusion detection system should detect network data that does not conform to the expected protocol format.

- Persistent storage holds user data generated by applications, plus cached credentials. Disk encryption is essential to data security. Self-encrypting drives can be used so that all data at rest is always stored securely.

It is also important to establish a maintenance cycle for each device and keep up to date with new security threats and responses for the particular software products that you are running.

Workstations

Workstations operate at the frontline of an organization's activities and present unique concerns regarding endpoint hardening compared to other devices. Due to the varied tasks and numerous applications associated with workstation use, they generally have a large attack surface. Hardening practices to minimize this attack surface include removing unnecessary software, limiting administrative privileges, strictly managing application installations and updates, and many other changes. Furthermore, since employees operate workstations, user-focused security strategies are essential, including regular training and awareness activities to educate users about threats such as phishing and promoting secure behaviors such as strong password practices, responsible Internet use, and careful handling of sensitive data, among other practices.

Additionally, configuring workstation settings for increased security, like automatic updates, screen locks, firewalls, endpoint protection, intrusion detection and prevention, increased logging, encryption, monitoring, and many other protections, are essential. Also, the need to secure peripheral devices like USB ports is unique to workstations. It is often achieved using features of endpoint protection software and the implementation of strict device control policies. Lastly,

given the various roles and responsibilities assigned to different workstations, segmentation is crucial to restrict communications and limit the potential for malware or attackers to propagate across the network.

Installing Endpoint Protection

To ensure maximum protection and efficient management, deploying and managing endpoint protection agents on workstations, laptops, and servers in an enterprise environment requires strategic planning and adherence to established best practice configuration and management practices.

Create a deployment plan with considerations such as the deployment order (such as which devices or departments get agents first), time frames, and leveraging stages to limit potential disruptions caused by endpoint protection settings.

Standardize configurations for endpoint protection across all devices to ensure consistency in protection levels and simplify compliance management.

Automate deployments using tools like Microsoft's System Center Configuration Manager (SCCM), Group Policy, or third-party solutions to save time, improve consistency, and reduce the risk of human error.

Updates and patches to endpoint protection agent software and definitions are required to ensure the highest levels of protection against the latest known threats.

Monitor endpoint protection agents to check for alerts or signs of potential security incidents, verify that agents are running, and ensure that updates and patches are applied successfully.

Centralize management to provide a comprehensive view of endpoint configurations, updates, and status. Centralized management also allows administrators to enforce global security policies.

Patch Management

No operating system, software application, or firmware implementation is free from vulnerabilities. As soon as a vulnerability is identified, vendors will try to correct it. At the same time, attackers will try to exploit it. Automated vulnerability scanners can effectively discover missing patches for the operating system, plus a wide range of third-party software apps and devices/firmware. Scanning is only useful if effective procedures are i n place to apply the missing patches.

In residential and small networks, hosts are typically configured to auto-update, meaning they check for and install patches automatically. The major OS and applications software products are well supported in terms of vendor-supplied fixes for security issues. In Windows, this process is handled by Windows Update, while in Linux, it can be configured via yum-cron or apt unattended upgrades , depending on the package manager used by the distribution.

There can also be performance and management issues when multiple applications run update clients on the same host. For example, as well as the OS updater, there is likely also a security software update, browser updater, Java updater, OEM driver updater, and so on. These issues can be mitigated by deploying an enterprise patch management suite. Some suites, such as Microsoft™ System Center Configuration Manager (SCCM)/Endpoint Manager (docs.microsoft.com/en-us/mem/configmgr), are vendor-specific, while others are designed to support third-party applications and multiple OSes.

Testing patches before deploying them into the production environment is crucial for maintaining the stability and security of software. By conducting thorough testing, organizations can identify potential issues or conflicts arising from the patch, ensuring that it does not introduce new vulnerabilities or disrupt critical operations. Testing helps mitigate the risk of unintended consequences and facilitates a more controlled deployment process, ultimately safeguarding the integrity and

reliability of the environment. Testing is typically performed in testing environments built to mirror the production environment as much as appropriate.

Patch management can be difficult for legacy systems, proprietary systems, and systems from vendors without robust security management plans, such as some types of Internet of Things devices. These systems will need compensating controls or some other form of risk mitigation if patches are not readily available.

OS Hardening Best Practices

Different hardening approaches are required to protect endpoints in response to varied and constantly evolving cybersecurity threats. These threats require a layered and comprehensive defense strategy addressing vulnerabilities at multiple levels, from physical access to network protocols, operating system configurations, and user behaviors.

Technique	Definition
Access controls	Access control refers to regulating and managing the permissions granted to individuals, software, systems, and networks to access resources or information. Access controls ensure that only authorized entities can perform specific actions or access certain data, while unauthorized entities are denied access. Access control concepts apply to networks, physical access, data, applications, and the cloud. *Access control lists* (ACLs) in computer systems and networks are used to enforce access control policies. An ACL is a list of rules or entries that specify which users or groups are allowed or denied access to specific resources or perform certain actions. In networks, ACLs are associated with routers, firewalls, or similar devices and define rules that determine how network traffic is filtered or forwarded based on criteria like source IP addresses, destination IP addresses, ports, or protocols. ACLs can help to control network access and protect against unauthorized or malicious activities. ACLs control access to files, directories, or system resources in operating systems and file systems. Each access control entry (ACE) typically contains a user or group identifier and associated permissions controlling actions that are allowed or denied. These permissions often include read, write, execute, and sometimes more granular limits such as modify, delete, or list. While ACLs offer flexibility and control, managing complex access control policies with numerous ACL entries can become challenging. Complexity increases the risk of misconfigurations. Therefore, proper planning, periodic reviews, and best practice configurations are essential when implementing and maintaining ACLs.
Principle of least privilege	Implementing the *principle of least privilege* (PoLP) is a cornerstone of improving endpoint protection and minimizing the risk of security issues. The principle of least privilege dictates that users, applications, and processes should only be granted the minimum permissions necessary to complete their duties and nothing more. There are several practical methods for implementing least privilege. An essential first step to effectively implementing least privilege is thoroughly auditing user roles, privileges, and responsibilities. This process allows organizations to understand what access each user needs to perform their job role effectively. Access controls and permissions can be adjusted to adopt a principle of least privilege that best reflects the audit results.

	The principle of least privilege also applies to software applications and operating systems, not just to users. For instance, ensuring that applications run with the minimum necessary permissions can prevent them from being exploited to carry out privileged actions.
Application allow lists and block lists	One element of endpoint configuration is an execution control policy that defines applications that can or cannot be run. An allow list (or approved list) denies execution unless the process is explicitly authorized. A block list (or deny list) generally allows execution but explicitly prohibits listed processes. The contents of allow lists and block lists need to be updated in response to incidents and ongoing threat hunting and monitoring. Threat hunting may also provoke a strategic change. For example, if you rely principally on explicit denies, but your systems are subject to numerous intrusions, you will have to consider adopting a "least privileges" model and using a deny-unless-listed approach. This sort of change can be highly disruptive, however, so it must be preceded by a risk assessment and business impact analysis.
Monitoring	Monitoring plays a vital role in endpoint hardening, helping to enforce and maintain the security measures put in place during the hardening process. Once devices are hardened, monitoring helps to ensure these conditions remain in place. Security analysts can detect changes that weaken the hardened configuration through continuous monitoring. For instance, if a previously disabled port is detected as open or a service that was disabled is changed to enabled, monitoring tools can alert analysts of the change, which may indicate a breach. Additionally, monitoring can provide valuable data for compliance and auditing purposes. Regular reports on the status of endpoint devices can verify that hardening baselines have been effectively deployed and maintained, supporting compliance with various regulations and industry standards.
Configuration enforcement	Configuration enforcement describes methods used to ensure that systems and devices within an organization's network adhere to mandatory security configurations. Configuration enforcement generally depends upon a few important capabilities. **Standardized configuration baselines** are defined by organizations like NIST, CIS, or the organization itself and used as the benchmark for how systems and devices should be configured. **Automated configuration management tools** are used to apply and maintain standardized configuration baselines across the environment automatically. **Continuous monitoring and compliance checks** are crucial to detect deviations from mandatory configurations.

	Change management processes ensure configuration changes are properly reviewed, tested, and approved before implementation.
Decommissioning	Decommissioning processes play a vital role in supporting security within an organization. When a device is no longer needed, it often contains residual data, potentially sensitive information, and system configurations that could be exploited. A thorough and systematic decommissioning process ensures that all data is securely erased or overwritten to reduce the risk of exposure. Decommissioning also involves resetting devices to their factory settings and eliminating any residual settings. Updating inventory records during decommissioning is also important to maintain an accurate account of active assets and support compliance requirements that mandate accurate asset tracking and secure disposal.
Changing defaults and removing unnecessary software	Changing default passwords and removing unnecessary software are two fundamental practices in hardening an endpoint to strengthen its security posture. Default passwords, often set by manufacturers, are widely known and easily discoverable, making devices that use them particularly vulnerable to unauthorized access. Therefore, changing these passwords to strong, unique credentials is crucial as part of the initial setup process for any device or system. Removing unnecessary software is another critical step when hardening an endpoint. Each software application introduces potential vulnerabilities that malicious actors could exploit. The attack surface is significantly reduced by reducing the number of software applications to only those necessary for the device's intended function. This includes removing unnecessary applications and disabling unnecessary features or services within the remaining applications. This practice simplifies the maintenance and patch management process because there are fewer applications to update, reducing the chances of missing a critical security patch.

Encryption Techniques

Endpoint encryption is critical to protecting sensitive data, especially in an enterprise setting. Several different approaches are required to protect data on endpoints. Some important ones include the following:

Full Disk Encryption (FDE) encrypts the entire hard drive of a device. It ensures that all data, including the operating system and user files, are protected even while the operating system is not running. Tools like BitLocker for Windows and FileVault for macOS provide full disk encryption capabilities.

Removable Media Encryption ensures that data remains protected even when physically removed from devices such as SDCards or USB mass storage devices. Many FDE tools also include options for encrypting removable media.

Virtual Private Networks (VPNs) complement endpoint encryption by providing a secure tunnel for data transmission that protects against eavesdropping, on-path, and many other attack types.

Email Encryption protects sensitive information stored in emails using protocols like PGP (Pretty Good Privacy) or S/MIME (Secure/Multipurpose Internet Mail Extensions) .

8.1.3 Hardening an Operating System (Demo Video)

Transcript:

Let's take a look at some general strategies for hardening an operating system. Here we are on a domain controller running Windows Server. Let's go to Tools and go to Active Directory Users and Computers. There are a lot of options here for locking things down. The default user is the administrative user, and that's a very well-known account. It's built into the system, so a lot of people understand what it is and what it does.

One thing you might consider doing is renaming the account in Properties, or you could create a new account for the administrator. Be aware that the Administrator account has many groups assigned to it, such as domain admins, enterprise admins, and schema admins. By default, the Domain Admins group grants the rights to configure group policies.

Samantha Carter has been promoted to a junior administrator, so we need to elevate her permissions for this new role. We can go to Properties, Member Of, and then Add. Type 'domain admins' and hit OK. Then you can disable the administrative account and just use this account, which won't be well known to people outside of your system.

If you do disable the administrative account, be aware that it's the original admin account, and it's the only one that you can't lock with account lockout. So be careful about disabling it. You don't want to get locked out of your system or your server.

You'll also want to change passwords. Windows Server requires you to enter a complex password right after you've installed the operating system. You'll need to change any default account names and passwords and use complex passwords. To change your password, you just right-click on the account and go to Reset Password. That's relatively simple.

You'll also notice that there are a lot of built-in groups in Active Directory. The Users container, on the left, contains all of the built-in groups that come on your server by default. These groups can help you control what users can access and what they can do. For example, when you add somebody to the Backup Operators group, that user has the power to back up and restore files.

Let's go ahead and go to our Group Policy in Group Policy Manager. Go to Tools, and then we'll go to Group Policy Management. We're going to go to Domain Controllers and the Domain Controller default policy. Right-click. Edit. These are all the Group Policies that affect our domain controller. Over here, under Computer Configuration, we're going to go to Policies > Windows Settings > Security Settings.

You can see settings that you've enabled to lock down the domain controller behavior. We're going to look under Security Settings. We're going to look at Local Policies, specifically User Rights Management. Under here, on the right-hand side, we're going to go to Back Up Files and Directories, and you can see that right here. This is basically the built-in groups that can back up files and do backups in the directories.

We have administrators, backup operators, and server operators. We can add users to this group if we want to. Let's also go down to Restore Files and Directories. Here are the same groups. They all have that same access. All three of these, administrators, backup operators, and server operators, can back up and restore files on your system. That's something to be aware of. If I give someone Backup Operator rights, they'll be able to restore and back up any files on the system.

On the left side, there are also security options. For security options, we don't care who's logged on. They affect everyone. Scroll down to Interactive Logon. Let's do Interactive Logon. Don't require Ctrl + Alt + Del right here. This option reduces your security posture because the malware can take advantage of the fact that the Ctrl + Alt + Del box isn't there.

Having Ctrl + Alt + Del can prevent some malware. If this is enabled, it could open your system to some problems. But you can only set this across the board for every user. You can't define which user can do this; this setting applies to everyone. In this case, we don't want to do this. We're going to hit Cancel. Notice that it didn't ask us which user or which group to apply this to, since it affects everyone.

Other hardening strategies include installing only required software on the systems. With Windows Server, we have the concept of roles. Server Manager is quite a bit different as well. Here, we're going to go to Add Roles and Features. We can also see Remove Roles and Features. It has a wizard to get you started.

We'll just click through a few. This is very different from older versions of Windows Server, but you can do role-based or feature-based installation, or Remote Desktop Service installation. We're just going to do role-based. Select the server you want it to be on. I'm going to select my server. You can see the server roles that you can add. If we go on one more, you can see features.

Windows Server only installs binaries for any service that you want to run on the server. This helps reduce the attack surface. You won't have a bunch of programs open by default. You have to go in, enable them, and turn them on. One major difference between older servers and newer servers is that the security configuration wizard has been completely removed, so features are secured by default.

You should use Group Policy Manager or Microsoft Security Compliance Manager to control specific security settings.
We can also go to our services on Server Manager by selecting Tools and then Services.
It's a good practice to disable or turn off at least the startup behavior of any services that you're not requiring on this particular machine. Microsoft will start up services related to the roles you've installed, but often, there may be extra services that aren't required for the operation of your system. You can go through and look at all the services that are started automatically. For example, there's a service called SSDP that we're going to look at.
SSDP Discovery is a universal plug-and-play type of hardware on your system. It's universal plug-and-play for network devices. At one time, there were some flaws in it, and it's automatically disabled by default. You'll want to be careful not to disable a service that may be critical. Always do your research first.
That's it for this demo. In this demo, we discussed some strategies you can use to harden your Windows Server operating system.

8.1.4 Managing Automatic Updates (Demo Video)

Transcript:

In this demonstration, we're going to talk about configuring Windows Update.

As you probably know, every now and then, the Windows operating system goes out to Microsoft's site over the internet and checks whether there are any updates available for the operating system.
To manage updates on a Windows system, you need to come down to your Windows icon. Go to Settings and then Windows Update.
On the Windows Update screen, I can see the current status of my updates. Right here, you can see when my device was last updated. To be sure my system is up to date, I can go here and select Check for updates. When I do that, Windows tells me it's up to date.
Under Advanced Options, we next have the option to pause Windows updates for seven days. When I select this option, it'll pause my updates. And up here, you can see when the updates will resume. I don't want to pause my updates, so I'll click on Resume updates.
This option allows us to set the active hours on our system. A long time ago, when dinosaurs roamed the earth, there was nothing worse than working on a term paper and having Windows spontaneously decide it was a great time to install an update. The system would log you off, and hopefully, you'd have a saved copy of your work. If not, you might have to start all over.
So, this option lets you set active hours to let the device know when you typically work on your system. This is to avoid updating when you're in the middle of something without checking with you first. I like to work a lot, so I'll put in 16 hours. I'd like to change this to 7:00 a.m. until about 11:00 p.m.
Here, I can select Update History. When I do, this Window appears, and I can see the name of the updates and the date they were installed. If I need to know more about what an update is, I can click one of the links, and it takes me to the Microsoft Knowledge Base site for that particular update.
Below there are two options to be aware of. One is Uninstall updates, and the other is Recovery options. The Uninstall updates open another window where you can uninstall certain updates. However, some updates can't be removed from Windows.
Recovery options take you to where you can do a system reset, which isn't part of this demo.
Let's go back a few clicks.
Under Advanced Options, we do other things, like tell Windows to give us updates for other Microsoft products when we update. For example, I might want Office to be updated when updates run.
Here, we can tell Windows not to download when connected to metered connections. If we're connected to a cellular network and paying for bandwidth, we might not want to do that. Right now, that's off, and I'm going to leave it that way.
Here, you can tell Windows to restart as soon as possible when a restart is required to install an update. If you have this turned on, it'll warn you before restarting. You can tell Windows to show a notification when your PC requires a restart to finish an update by turning this On.
Okay, now let's move on to our delivery options. We're going to talk about a more advanced topic for a moment. It's possible to set up an update server on your local network and configure your workstations to get your updates from that server. This is a good option if you have a lot of workstations.
Instead of having all these workstations in your organization download the same files redundantly from Microsoft, wasting bandwidth, we'd want to download those updates once to the update server. Then all the systems on your

network would get the updates from that local server. Windows is taking that concept and making it more of a peer-to-peer model instead of a client-server model.
Essentially, what we can do is get our updates from Microsoft directly. We can also get updates from other workstations on our network that have already downloaded that same update. We can turn that functionality off or on right here. By default, it's turned On.
One option is only the PCs on my local network, which is selected by default. That's a pretty good idea. If you're a little more trusting, you can also get updates from computers out on the internet. This option scares me since I have no idea what I'd be getting from other computers, so I don't usually select it.
Right below this, we have Advanced options. Here, we can change the default settings for how much bandwidth we'll allow Windows to use for downloading and uploading updates on the system. We'll click back a few times, which wraps up Windows Update.
One last topic we need to cover before we end this demonstration: how to include device updates with Windows Update. This is usually a very good idea. The ironic thing is that finding this option can be challenging because when Windows releases featured updates, they often make things harder and harder to locate. That's what happened to the device update options.
First, we need to go to Bluetooth & devices settings. Now, go to Devices, More devices, and printer settings. I'm going to right-click the PC icon. From the menu, I'm going to select Device installation settings on this system.
Here, it says, Do you want to automatically download manufacturers' apps and custom icons available for your devices? This is set to Yes by default. I wanted to confirm that, so I'll leave it alone.
That's it for this demonstration. In this demo, we explained the process of managing Windows Update.

8.1.5 Configure Automatic Updates (Simulation)

Scenario

You need to customize how Windows Update checks for and installs updates on the ITAdmin desktop system.

In this lab, your task is to:

- Configure Windows Update to:
  - Install updates for other Microsoft products when Windows is updated.
  - Allow the installation of feature updates to be deferred 60 days.
  - Allow quality updates to be deferred 30 days.
- Configure Windows to automatically download manufacturers' apps and custom icons for devices.

Explanation

Complete this lab as follows:

- Configure the Windows Update settings.
  - Right-click **Start** and then select **Settings** .
  - Maximize the window for better viewing.
  - Select **Update & Security** .
  - From the right pane, select **Advanced options** .

Under Update Options, turn on **Receive updates for other Microsoft products when you update Windows** by sliding the switch to **On** .

Under *Choose when updates are installed* , configure each option as follows:

A feature update includes new capabilities and improvements. It can be deferred for **60** days.

A quality update includes security improvements. It can be deferred for this many days: **30**

Configure Windows to automatically download the manufacturer's apps and custom icons.

In the upper left of the Settings app, select the ***Home*** icon to return to the home page.

Select **System** .

From the left pane, select **About** .

From the right, under *Related settings* , select **Advanced system settings** .

Select the **Hardware** tab.

Select **Device Installation Settings** .

Select **Yes** and then select **Save Changes** .

Select **OK** .

8.1.6 Configure Microsoft Defender Firewall (Demo Video)

Transcript:

In this demonstration, we'll practice working with the Windows Defender Firewall. Windows Defender Firewall is a host-based firewall. It's implemented as software and designed to protect an individual system.

Be aware that Windows Defender Firewall was previously referred to as Windows Firewall. If you're on an older operating system, it may go by that name. However, it works basically the same. Its job is to prevent someone on the internet or the network from initiating an unwanted connection with a system. It just shuts it down.
To manage Windows Defender Firewall, I'll click on Search and type firewall, then select Windows Defender Firewall under Best match. You can see that the Windows Defender Firewall is currently Off. Let's click Turn Windows Defender Firewall on or off on the left. You'll see two network profiles to which the Windows Defender firewall is applied. We have the Private network settings and the Public network settings.
The Private network settings can be a little looser because we're assuming the company has a network firewall that's already blocking many connections, increasing the security level. We're trying to protect this individual host.
We want to customize the firewall for those times when we connect to a public network. Public networks, such as those defined at a restaurant, a hotel, or an airport, are like the wild, wild West of information technology. You have no idea who's on the network or their intentions. Therefore, you want to configure the Windows Defender Firewall with more stringent settings than when you're on a private network.
For both our network profiles, you can see that the Windows Defender Firewall is currently turned off. We need that firewall on. Select on for both. The default settings work well for a private network. We can see that we'll be notified if

Windows Defender Firewall blocks an app trying to communicate through the firewall. We'll have a list of apps allowed to communicate through the firewall.
That's probably appropriate. We'll run certain applications that need to send data back and forth through the host-based firewall. So that's okay. However, if I'm on a public network at an airport, a hotel, or a similar place, we want to turn this option on and block all incoming connections, including those in the list of allowed apps.
We don't want anyone on the public network initiating a connection with this computer, even if it's an allowed application. We'll leave this option checked for public network profiles and click OK. The Windows Defender Firewall state is on for incoming connections.
Let's talk about allowing certain apps. There may be times when you install an application that legitimately needs to communicate through the Windows Defender Firewall with other hosts on the network. Still, by default, it's going to be blocked. In that case, you can use the Allow an app or feature through Windows Defender Firewall. Let's select that.
You can see a list of applications and features that the Windows system is aware of. You can also see whether they're allowed through the firewall. For example, scroll down to Remote Assistance. Remote Assistance traffic is allowed through the host firewall for private and public profiles.
If there's an application that you need to allow through the firewall, you can enable it using the checkbox. For example, we've enabled Remote Desktop for Public and Private profiles. It's an app we frequently use for testing all sorts of networks.
There may be situations where you want to allow an application to communicate through the Windows Defender Firewall. Still, you can't find it in the list because Windows hasn't recognized it.
If that's the case, you can come down here and click Allow another app. Then, you locate the app. We have an app in the Program Files directory named VNC Viewer. VNC Viewer allows you to connect to desktops remotely for Windows, Linux, and other systems that won't work with a Remote Desktop.
We'll go ahead and select vncviewer. Click Add. Now you can see it's added. We can configure it to allow traffic from both the Public and Private network profiles. That's how you add an app to the list of apps that can communicate through the firewall. Click OK. Now, we've configured the Windows Defender Firewall on the system.
That's it for this demonstration. In this demo, we talked about managing the Windows Defender Firewall. We first turned on the Windows Defender Firewall and increased the security level of the Windows Defender Firewall for the public profile. We ended this demo by adding an exception to the firewall to allow a specific application to communicate through it.

8.1.7 Configure Microsoft Defender Firewall (Simulation)

Scenario

You have a new laptop that is running Windows 10. You notice a security message that indicates that Windows Firewall has been disabled. The laptop is currently connected to your organization's network, and the Domain network profile settings are in effect. You plan to travel this week and connect the laptop to various airport Wi-Fi hotspots. You need to enable Windows Firewall for any public network.

In this lab, your task is to configure Windows Firewall as follows:

- Turn on the Windows Firewall for the Public network profile.
- In addition to the programs and ports currently allowed, allow the following service and programs through the firewall for only the Public network profile:
  - A service named **Key Management Service**
  - An application named **Arch98**
  - An application named **Apconf**

Explanation

To complete this lab, you need to allow the following service and programs through the firewall for the Public network profile only:

A service named **Key Management Service**

An application named **Arch98**

An application named **Apconf**

Leave all other existing apps and features as they are.

Complete this lab as follows:

Turn on the firewall for the public network.

Right-click **Start** and then select **Settings** .

Select **Network & Internet** .

From the right pane, scroll down and select **Windows Firewall** .

From the *Firewall & network protection* dialog, under Public network, select **Turn on** .

Allow applications to communicate through the firewall for the Public network only.

Select **Allow an app through firewall** .

Select **Change settings** .

For *Key Management Service,* clear **Domain** and **Private** , and then select **Public** .

Select **Allow another app** to configure an exception for an application not currently allowed through the firewall.

Select the ***application*** from the list and then select **Add** .

For the newly added application, clear **Domain** and **Private** , and then select **Public** .

Repeat steps 3d - 3f for the remaining ***application*** .

Select **OK** .

8.1.8 Practice Questions (Section Quiz)

q_harden_allow_block_lists_secp8

You are the IT Security Specialist at a financial institution. The company has just set up a new server that will host a critical application.

As part of the company's OS hardening policy, you are tasked with ensuring the server is secure before it goes live. One of the key requirements is to minimize the server's attack surface.

What is the MOST effective way to achieve this?

Answers:

Install the latest antivirus software on the server.

***Implement allow and block lists to control which applications and services can run on the server.**

Regularly update the server's operating system and all installed applications.

Enforce a strict password policy for all users who will have access to the server.

Explanation:

Implementing allow lists and block lists is the correct answer. It is an effective way to control which applications and services can run on the server. By only allowing necessary applications and services to run, you can significantly reduce the server's attack surface.

While installing the latest antivirus software is an important step in securing the server, it does not directly contribute to minimizing the server's attack surface. The attack surface is reduced by limiting the number of applications and services that can run on the server.

Regularly updating the server's operating system and all installed applications is a crucial part of maintaining security, but it does not directly minimize the server's attack surface. The attack surface is minimized by limiting the number of applications and services that can run on the server.

Enforcing a strict password policy is an important part of securing the server, but it does not directly contribute to minimizing the server's attack surface. The attack surface is reduced by limiting the number of applications and services that can run on the server.

q_harden_auto_updt_secp8

Which of the following tools can you use on a Windows network to automatically distribute and install software and operating system patches on workstations? (Select two.)

Answers:

***Group Policy**

***WSUS**

Security Templates

Security Configuration and Analysis

Configuration baseline

Explanation:

Windows Software Update Services (WSUS) is a patch management tool that allows clients on a network to download software updates from an internal WSUS server in their organization.

The WSUS server receives a list of available updates from Microsoft.

On the WSUS server, you identify allowed or required patches for your organization.

Clients download only approved patches from an internal WSUS server or directly from Microsoft.

You can also use Group Policy to distribute and automatically install patches. You must use Group Policy to install updates to non-Microsoft software that is not supported with WSUS.

Use the Security Templates snap-in to create and edit templates that enforce system security settings.

Use the Security Configuration and Analysis snap-in to compare the existing settings with the template or to apply a template to a single device.

A configuration baseline is a set of consistent requirements for a workstation or server. However, baselines are not directly associated with automatically distributing and installing software and operating system patches on workstations.

q_harden_baseline_secp8

Which of the following BEST describes a configuration baseline?

Answers:

***A list of common security settings that a group or all devices share.**

A collection of security settings that can be automatically applied to a device.

A set of performance statistics that identifies normal operating performance.

The minimum services required for a server to function.

Explanation:

A configuration baseline is a set of consistent requirements for a workstation or server. Configuration baselines include a component that ensures that all workstations and servers comply with the security goals of the organization.

A security template is a saved set of configuration values that produce the system configuration specified in the configuration baseline. When you apply the security template to a system, the settings within the template are applied to the system.

A performance baseline is a set of performance statistics that identify normal operating performance.

q_harden_configuration_enforcement_secp8

You are the IT Security Manager at a large corporation. The company has just acquired a batch of new servers that will be used to host critical applications.

As part of the company's OS hardening policy, you are tasked with ensuring these servers are secure before they are deployed.

What should be your first step?

Answers:

Install the latest antivirus software on the servers.

Enforce a strict password policy for all users who will have access to the servers.

***Apply a configuration baseline template to the servers to ensure they are configured according to industry security standards.**

Connect the servers to the network to monitor for any potential security threats.

Explanation:

Applying a configuration baseline template is the correct answer, as it ensures that the servers are configured according to industry security standards. This reduces the potential attack surface and is the first step in securing the servers.

While installing the latest antivirus software is an important step in securing the servers, it should not be the first step. Before any software is installed, the servers should be configured to a secure baseline.

Enforcing a strict password policy is also an important part of securing the servers, but it is not the first step. Before users are given access to the servers, they should be configured securely.

Connecting the servers to the network before they have been properly secured could expose them to potential security threats. This should only be done after the servers have been configured securely.

q_harden_harden_secp8

By definition, what is the process of reducing security exposure and tightening security controls?

Answers:

Social engineering

***Hardening**

Active scanning

Passive reconnaissance

Explanation:

Hardening is the process of securing devices and software by reducing security exposure and tightening security controls.

Social engineering is the act of exploiting human nature by convincing someone to reveal information or perform an activity.

Active scanning and passive reconnaissance are types of reconnaissance attacks.

q_harden_limit_privileges_secp8

A small IT company is experiencing an increased number of cyberattacks. Its server uses default settings from the developer, which the company believes is a potential source of vulnerability.

Which of the following changes should the IT company consider to improve the server's security?

Answers:

***Limit the privileges of each user on the server.**

Continue to use the default settings but increase monitoring efforts.

Switch off the server whenever it is not in use.

Ignore software and security patches and updates.

Explanation:

Limiting the privileges of each user on the server to the least amount necessary to perform their function reduces the impact of a compromised account. This is part of the principle of least privilege and is a recognized method for hardening server security.

Although increasing monitoring efforts can help identify and respond to security incidents, it does not fundamentally reduce the potential vulnerabilities in the default server settings.

Switching off the server when not in use may reduce the exposure to potential attacks, but it may not be feasible due to the need for constant availability.

Ignoring software security patches and updates is risky behavior; the IT department should apply them consistently and timely as part of a secure configuration approach.

q_harden_removable_media_encryption_secp8

You are the IT Security Manager at a healthcare organization. The organization frequently uses removable media devices like USB drives to transfer patient data between different departments.

Given the sensitive nature of the data, you are tasked with ensuring the data remains secure during transfer.

What is the MOST effective way to achieve this?

Answers:

Implement a strict password policy for all users who will have access to the data.

Install the latest antivirus software on all computers that will be used to transfer the data.

***Encrypt the data on the removable media devices.**

Regularly update the operating systems and all installed applications on the computers that will be used to transfer the data.

Explanation:

Encrypting the data on the removable media devices is the correct answer. It ensures that even if the devices are lost or stolen, the data cannot be accessed without the encryption key.

While implementing a strict password policy is an important part of securing the data, it does not directly protect the data during transfer. The data is most vulnerable when it is stored on the removable media devices, so it should be encrypted to ensure its security.

Installing the latest antivirus software is an important step in securing the computers, but it does not directly protect the data during transfer. The data is most vulnerable when it is stored on the removable media devices, so it should be encrypted to ensure its security.

Regularly updating the operating systems and all installed applications is a crucial part of maintaining security, but it does not directly protect the data during transfer. The data is most vulnerable when it is stored on the removable media devices, so it should be encrypted to ensure its security.

q_harden_role_separation_secp8

As a system administrator, you are tasked with hardening the system in your organization.

Which of the following strategies is MOST effective in reducing the impact if a single system is compromised?

Answers:

Installing anti-virus software on all systems

Regularly updating all software to the latest version

***Role separation**

Using complex passwords

Explanation:

Role separation is the correct answer. Role separation involves installing services on separate physical systems. This means that if a single system is compromised, only the few services on that system will be affected. This strategy is most effective in reducing the impact if a single system is compromised.

While installing anti-virus software on all systems is a good security practice, it does not specifically address the issue of reducing the impact if a single system is compromised. Anti-virus software helps to protect individual systems from malware, but it does not prevent the spread of a compromise from one system to another.

Regularly updating all software to the latest version is also a good security practice, as it ensures that all known vulnerabilities are patched. However, this does not specifically address the issue of reducing the impact if a single system is compromised.

Using complex passwords is a good security practice, as it makes it harder for unauthorized users to gain access to systems. However, this does not specifically address the issue of reducing the impact if a single system is compromised.

q_harden_security_baseline_secp8

A global corporation has faced numerous cyber threats and is now prioritizing the security of its servers. The corporation's IT security expert recommends a strategy to improve server security.

Which of the following options is likely to be the MOST effective?

Answers:

***Implement a security baseline, consistently apply updates and patches, and adhere to hardening guidelines.**

Enable all services on the servers to maximize functionality.

Utilize easily-remembered, simple passwords to improve server manageability.

Switch off all security features to enhance server performance and reduce latency.

Explanation:

By establishing a security baseline, applying regular updates and patches, and adhering to hardening guidelines, the servers' security can be significantly improved, reducing the risk of cyber threats.

Enabling all services on a server may unnecessarily increase its attack surface. This strategy is more likely to make servers vulnerable to cyber attacks.

Despite the ability to easily remember them, simple passwords are a significant security risk as cyber attackers can easily guess or crack them.

Turning off all security features might enhance performance but significantly compromise server security. It is crucial to strike a balance between performance and security, and under no circumstances should the IT security expert disable all security features.

q_harden_services_secp8

Which of the following actions should you take to reduce the attack surface of a server?

Answers:

***Remove unused services.**

Install anti-malware software.

Install the latest patches and hotfixes.

Install a host-based IDS.

Explanation:

Attack surface reduction (ASR) cuts down on the software or services running on a system. By removing unnecessary software, features, or services, you eliminate possible attacks directed at those components. When removing unnecessary components, you should:

Use role separation by installing services on separate physical systems. If a single system is compromised, only the few services on that system are affected.

For many new systems, unnecessary services are often installed by default. Following installation, remove unneeded services, protocols, and applications.

When removing existing services, determine the unneeded services and their dependencies before altering the system.

Adding anti-malware or a host-based intrusion detection system (IDS) adds a level of protection (defense in depth) but does not reduce the number of components running on the system.

Applying patches is necessary to fix security problems with software or the operating system. But if the system is not running a specific piece of software, the patches that apply to that software are irrelevant and do not need to be applied.

q_harden_settings_secp8

Which of the following do security templates allow you to do? (Select two.)

Answers:

***Quickly apply settings to multiple computers.**

Apply new software patches.

***Configure consistent security settings between devices.**

Block malicious websites.

Fix a specific software problem.

Explanation:

Security templates allow you to quickly and consistently apply settings to multiple computers in order to bring them into compliance with a security baseline.

Security templates are not used to apply new patches, block malicious websites, or fix specific software problems.

q_harden_test_patches_secp8

You are the IT manager of a mid-sized company. Your team has just received a critical security patch for your company's primary database software. The patch is meant to address a significant vulnerability that could potentially expose sensitive customer data.

However, applying the patch requires taking the database offline, which would disrupt operations.

What should you do?

Answers:

Apply the patch immediately to all systems to ensure the vulnerability is addressed as soon as possible.

Ignore the patch. The disruption to operations is too significant.

***Apply the patch to a test environment first, then roll it out gradually to the rest of the systems.**

Wait for a few weeks before applying the patch to see if any issues arise from other users.

Explanation:

Apply the patch to a test environment first is the correct answer. Testing the patch in a controlled environment allows you to identify and address any issues before rolling it out to the rest of the systems. This approach minimizes the risk of disruption to operations.

Applying the patch immediately to all systems could potentially cause unforeseen issues. If the patch has any bugs or compatibility issues, it could cause more harm than good.

Ignoring the patch is not advisable because it leaves the company vulnerable to the security threat the patch is meant to address. This could lead to a data breach, which would be far more disruptive to operations than applying the patch.

Waiting for a few weeks before applying the patch is not a good strategy. The longer the vulnerability remains unaddressed, the higher the risk of a security breach. It's important to address vulnerabilities as soon as possible, but in a controlled and measured way.

q_harden_third_party_secp8

You have just purchased a new network device and are getting ready to connect it to your network.

Which of the following actions should you take to increase its security? (Select two.)

Answers:

***Change default account passwords.**

Remove any backdoors.

***Apply all patches and updates.**

Conduct privilege escalation.

Implement separation of duties.

Explanation:

To secure new devices, apply all recent patches and updates and then change the default user account passwords. For some systems, you can also increase security by changing the default account usernames. Default account usernames and passwords are well-known and can be easily discovered.

A backdoor is an unprotected access method or pathway. Backdoors are added by attackers or programmers during development. Backdoors that are present on new devices are typically hard-coded and must be removed by editing the code.

Privilege escalation allows a user to take advantage of a software bug or design flaw in an application to gain access to system resources or additional privileges that are typically not available to normal users. Separation of duties is the concept of requiring the participation of at least two people to complete a task. This helps prevent insider attacks because no one person has end-to-end control, and no one person is irreplaceable.

8.2 File Server Security

As you study this section, answer the following questions:

How can you identify inherited permissions?

How do Share and NTFS permissions differ?

On which elements can NTFS permissions be set?

How can you view the users who have permissions for a particular drive?

In this section, you will learn to:

- Configure NTFS permissions.
- Disable inheritance.

Key terms for this section include the following:

Term	Definition
Shared folder	A folder whose contents are available over the network.
Network-attached storage (NAS)	A standalone storage device or appliance that acts as a file server.
Storage area network (SAN)	A special network composed of high-speed storage that is shared by multiple servers.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.2 Summarize fundamental security concepts. Physical security 1.4 Explain the importance of using appropriate cryptographic solutions. Encryption Level Full-disk File 2.2 Explain common threat vectors and attack surfaces. File-based 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Access control

Access control list (ACL)

Permissions

Least privilege

Hardening techniques

Removal of unnecessary software

3.2 Given a scenario, apply security principles to secure enterprise infrastructure.

Secure communication/access

Virtual private network (VPN)

Tunneling

Internet protocol security (IPSec)

4.1 Given a scenario, apply common security techniques to computing resources.

Hardening targets

Servers

4.2 Explain the security implications of proper hardware, software, and data asset management.

Acquisition/procurement process

4.3 Explain various activities associated with vulnerability management.

Identification methods

System/process audit

4.5 Given a scenario, modify enterprise capabilities to enhance security.

Implementation of secure protocols

File integrity monitoring

4.6 Given a scenario, implement and maintain identity and access management.

Provisioning/de-provisioning user accounts

Access controls

	Least privilege
TestOut Security Pro	3.1 Harden computer systems 3.1.1 Configure file system inheritance 3.1.3 Configure NTFS permissions 4.2 Implement Encryption Technologies 4.2.2 Encrypt files

8.2.1 File Server Security (Lesson Video)

Transcript:

File servers are an attractive target because they almost always store some type of valuable data, such as client contacts, credit card information, employee files, company performance records--the list goes on and on. In this lesson, we'll look at some steps you should take to properly secure your organization's file servers.

Let's start by looking at some of the best practices you should follow when it comes to file server security. Keep in mind that these are generic best practices that can be applied to any type of file server, whether it's a dedicated NAS, a SAN, a Microsoft server, or a Linux server.

The first best practice is to keep all file servers physically secure. Remember, it's very easy for someone to gain access to data if they have physical access to a system, so employ the appropriate physical controls with your file servers as you would with any other networking hardware device.

Next, is the principle of least privilege. This is the concept that users should only have access to the information and resources that are necessary for them to perform their job, and that's it. They shouldn't have any more privileges than they need. This helps prevent privilege creep, where a user slowly accumulates more and more privilege than they need to perform their job.

Another best practice is to use full-disk encryption on all storage mediums. This may or may not be possible for your organization depending on its policies. Encrypting an entire drive and keeping it encrypted as people work requires a significant amount of resources. Due to this resource overhead, it might not be feasible to use full-disk encryption. Instead, you might want to consider only encrypting backups.

Another option is to fully decrypt drives when they're powered on and encrypt them when the system shuts down. This may not prevent someone from transferring files to a USB drive, but does prevent someone physically stealing the entire drive or server.

Another security best practice that applies to almost every system, not just files servers, is to remove unnecessary software and disable unused services. You can think of this as a principle of least privilege with applications.

In other words, you should only have the applications and services that are necessary for the file server to function, and nothing more. Having unused applications or services increases the attack surface area of a system and makes securing it that much harder. In addition, the system is more susceptible to zero-day attacks.

The next practice you should employ is auditing. Make sure that your file server has proper auditing enabled that can track user behavior, such as when files are accessed, modified, deleted, and moved. This helps you identify abnormal behavior on the system and can even help you detect that your system has been compromised.

The last security best practice is to use implicit deny access control lists, or ACLs. ACLs control the system's permission. A good security practice is to prevent access to everything that isn't explicitly granted. In other words, deny access to everyone except people with explicitly granted permissions. This control is a part of the concept of least privilege mentioned earlier.

The opposite of implicit deny is explicit deny, meaning that you're only looking for people you want to deny access to. The problem with this approach is that you have to do a bit of guesswork and research to deny access to files. And if you happen to forget about a particular group or file tree, you could inadvertently give everyone access to sensitive files. As a result, your system will be more secure if you use implicit deny.

At some point, we all need to download or transmit files using the internet, which is inherently unsecure. Let's talk about different ways files can be transmitted across a network. Some of these protocols are secure, and some aren't. As a security administrator, you need to know the difference and decide which of these protocols to use on your systems.

File Transfer Protocol, or FTP, is an older TCP/IP protocol that's used for transferring files across systems. It was adopted as a TCP/IP standard through RFC 959 in 1985. FTP is inherently unsecure since it doesn't encrypt data, including usernames and passwords. As such, FTP shouldn't be used for transferring sensitive data over an unsecure network such as the internet. Another problem with FTP is that it allows anonymous user access. This option can be disabled, but it's still a security risk. If you must use FTP, there are ways to use it more securely by pairing it with an encryption protocol. There are a couple of ways to do this.

The first way is to use a VPN connection that wraps all communications, FTP packets included, in an encrypted data packet. This would encrypt all traffic between the host and the FTP file server. IPsec or SSH can be used to create secure tunneling with FTP to secure the transmission. When use with an SSH tunnel, FTP is called FTP over SSH, or Secure FTP.

Another way is to use FTPS. FTPS uses SSL and TLS encryption to secure data transmissions. FTPS is similar to HTTPS in that it uses the SSL and TLS cryptographic protocols to secure communications and also requires the use of SSL certificates to encrypt traffic.

Another protocol that you can use is the Secure Copy Protocol, or SCP. SCP is similar to the Linux copy command cp. SCP uses the Secure Shell Protocol, or SSH, which is a secure tunnel. SCP is an older protocol that's entirely text-basedâ€”that is, you need to type the command, including the directories to transmit, into a command line interface. While it's secure, it doesn't offer any type of directory traversing.

As a replacement for SCP, you can use SFTP. SFTP stands for Secure Shell File Transfer Protocol. Files are transferred through an SSH tunnel. SFTP isn't related to FTP at all. They're two completely different, incompatible protocols. SFTP typically uses SSH v2, the more secure version of Secure Shell Protocol. It uses a graphical interface, and it's more user-friendly.

That's it for this lesson. In this video, we discussed several best practices that can be used to secure your file servers and your organization's resources. We also discussed how to use an encrypted protocol to reduce the opportunity for an attacker to see sensitive information as you copy files across a network.

8.2.2 File System Security Facts

Managing the file system is a primary concern of IT professionals. The file system is responsible for storing and securing data. An organization depends on data and requires that it be secure and easily accessible.

This lesson covers the following topics.

- File system security
- Least privilege permission assignments
- Data transfer security protocols

File System Security

Tasks to secure file servers include:

- Prevent physical access.
- Implement the principle of least privilege.
- Use full-disk encryption on backups.
- Implement strong authentication.
- Remove unnecessary software and disable unused services.
- Use implicit deny access control lists (ACLs).

Use hidden folders and files.

Audit the file system.

When managing the security of the file system, be aware of the following:

The transfer of files between a client and a server is often unsecured. Use IPSec or a VPN between the server and the client to secure data as it travels through the network.

File and print resources are primarily vulnerable to denial-of-service (DoS) and access attacks.

Attacks on file servers are often directed against the NetBIOS protocol. To protect the server, verify that NetBIOS is not required on the server, disable the NetBIOS protocol on the server, and use a host-based firewall to close NetBIOS ports 135 and 137 - 139.

A *shared folder* is a folder whose contents are available over the network.

An *administrative* share is a shared folder that is available only to an administrative user.

Administrative shares are hidden. This means that the share will not display when a user browses a network computer.

By default, the root of every drive is an administrative share.

In Windows, you can create hidden shares by appending a $ sign to the end of the share name (for example, DataFiles$).

Users must know the name of the share to access it and have the appropriate access permissions.

Do not share the root directory with regular users.

With Windows Server 2008 and later, you can use File Server Resource Manager (FSRM) to control files saved on a file server.

Quotas limit the amount of data that can be saved within a folder. A hard limit prevents exceeding the quota limit, while a soft limit sends a message when the limit is exceeded.

File screens restrict the type of files that can be saved in a folder. For example, you can prevent media files (audio and video) or files with specific file extensions from being saved. An *active* file screen prevents saving the specified file types, while a *passive* screen monitors when the specified file types are added to the folder.

Least Privilege Permission Assignments

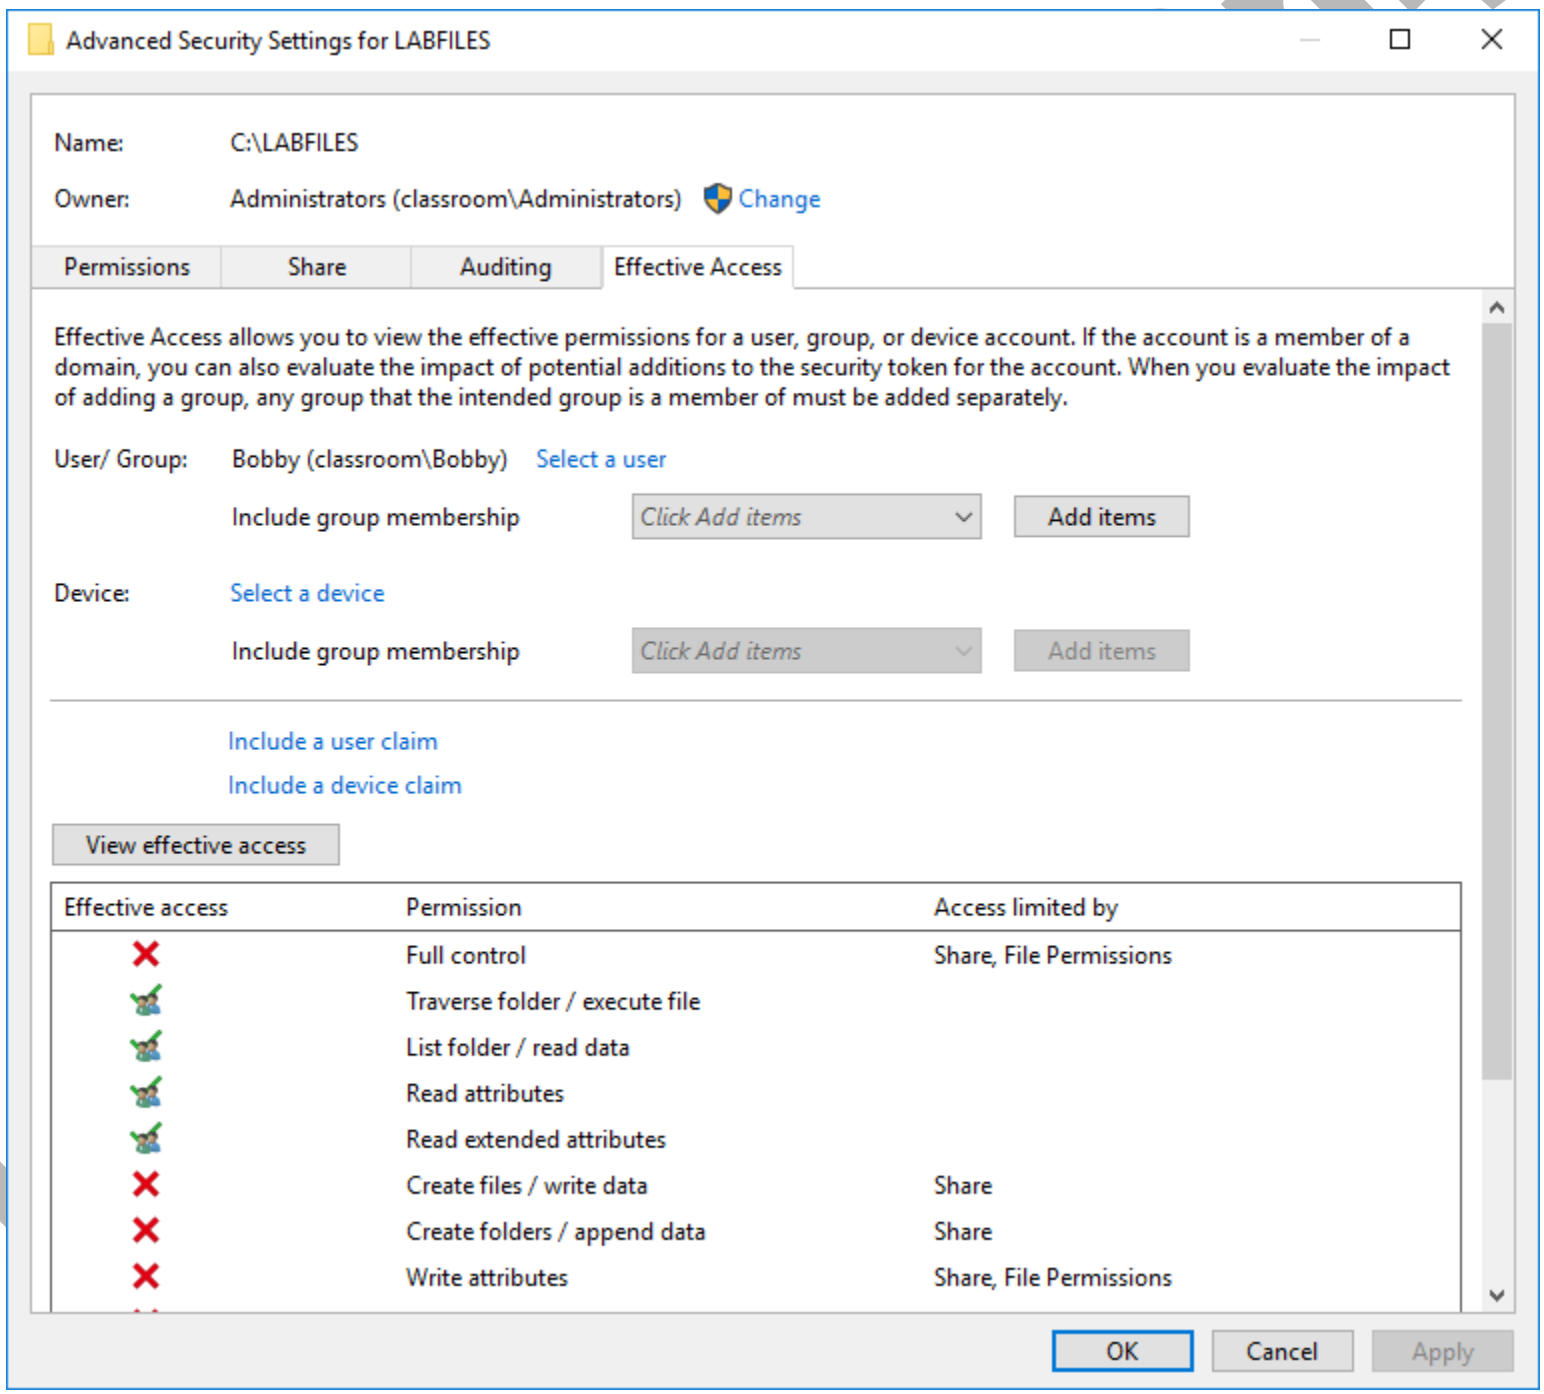
Least privilege means that a principal is granted the minimum possible sufficient rights to complete a task they are authorized to perform. This mitigates risk if an account should be compromised and fall under the control of a threat actor. Least privilege involves a design phase, where analysis of business workflows determines what roles and permissions are required.

While least privilege is a strong design principle, implementing it successfully can be challenging. Where many users, groups, roles, and resources are involved, managing permission assignments and implications is complex and time-consuming. Improperly configured accounts can have two different impact s . On the one hand, setting privileges that are too restrictive

creates a large volume of support calls and reduces productivity. On the other hand, granting too many privileges to users weakens the system's security and increases the risk of malware infection and a data breach.

Ensuring least privilege also involves continual monitoring to prevent authorization creep. Authorization creep refers to a situation where a user acquires more and more rights, either directly or by being added to security groups or roles.

For example, a user may be granted elevated privileges temporarily. In this case, a system is needed to ensure that the privileges are revoked at the end of the agreed period. A system of auditing should regularly review privileges, monitor group membership, review access control lists for each resource, and identify and disable unnecessary accounts.



Determining effective permissions for a shared folder. (Screenshot used with permission from Microsoft.)

Provisioning is the process of setting up a service according to a standard procedure or best practice checklist. The IT department must keep track of all assets under management, and user accounts are a type of asset. User accounts are provisioned for new employees and temporary access, such as by consultants and contractors. Some businesses may also need to set up customer accounts.

Provisioning a user account involves the following general steps:

Identity Proofing - verifies that the person is who they say they are by checking official documents and records. Circumstances might also demand a background check, which verifies current and previous addresses, education, or previous employment and whether the person has a criminal record or credit issues.

Issuing Credentials - allows the user to select a password known only to them and/or enroll them with biometric or token-based authenticators.

Issuing Hardware and Software Assets - the user will typically need a computer or smartphone and possibly local copies of licensed software apps. Employees need sufficient resources to do their job. If their resources are inadequate, they might try to obtain hardware and software directly (shadow IT).

Teaching Policy Awareness - by scheduling training and providing access to learning resources so that the employee or contractor is aware of security policies and risks. They must also be aware of policies for the personal use of any IT assets issued to them.

Creating Permissions Assignment - by identifying the work roles that the account must support and configuring the appropriate rights using a role-based, mandatory, or attribute-based access control model. If the account is granted privileged access, it should be tagged for close monitoring.

Deprovisioning is the process of removing the access rights and permissions allocated to an employee when they leave the company or from a contractor when a project finishes. This involves removing the account from any roles or security groups. The account might be disabled for a period and then deleted or deleted immediately.

Data Transfer Security Protocols

The following table describes considerations for securing file transfer using TCP/IP protocols:

Protocol	Description
File Transfer Protocol (FTP)	Be aware of the following when using FTP: *Anonymous login* (also known as *blind* or *anonymous FTP*) allows unrestricted access to the FTP server. Disable anonymous login to control access based on username. The username and password are transferred in cleartext and can be captured in transit by a sniffer. To protect logon credentials, implement a secure protocol, such as Secure Socket Layer (SSL). Use IPSec or a VPN tunnel to protect data transfers.

	The write permission allows users to upload files to the FTP server. Carefully restrict which users have the write permission. FTP uses port 21 for control information (such as logon) and port 20 for data transfer.
Trivial File Transfer Protocol (TFTP)	TFTP provides no authentication, encryption, or error detection. In addition, TFTP uses UDP instead of TCP. TFTP might be faster than FTP, but it does not perform error detection which could result in file errors.
Secure Copy Protocol (SCP)	SCP uses Secure Shell version 1 (SSH1) to secure file transfers and login credentials.
Secure Shell File Transfer Protocol (SFTP)	SFTP is a file transfer protocol that uses Secure Shell version 2 (SSH2) to secure data transfers. SFTP is not an FTP that uses SSH but rather a secure transfer protocol that is different from FTP.
Secure FTP	Secure FTP (also known as FTP over SSH) tunnels FTP traffic through an SSH tunnel.
FTP Secure (FTPS)	FTPS adds SSL or Transport Layer Security (TLS) to FTP in order to secure logon credentials and encrypt data transfers. FTPS requires a server certificate.

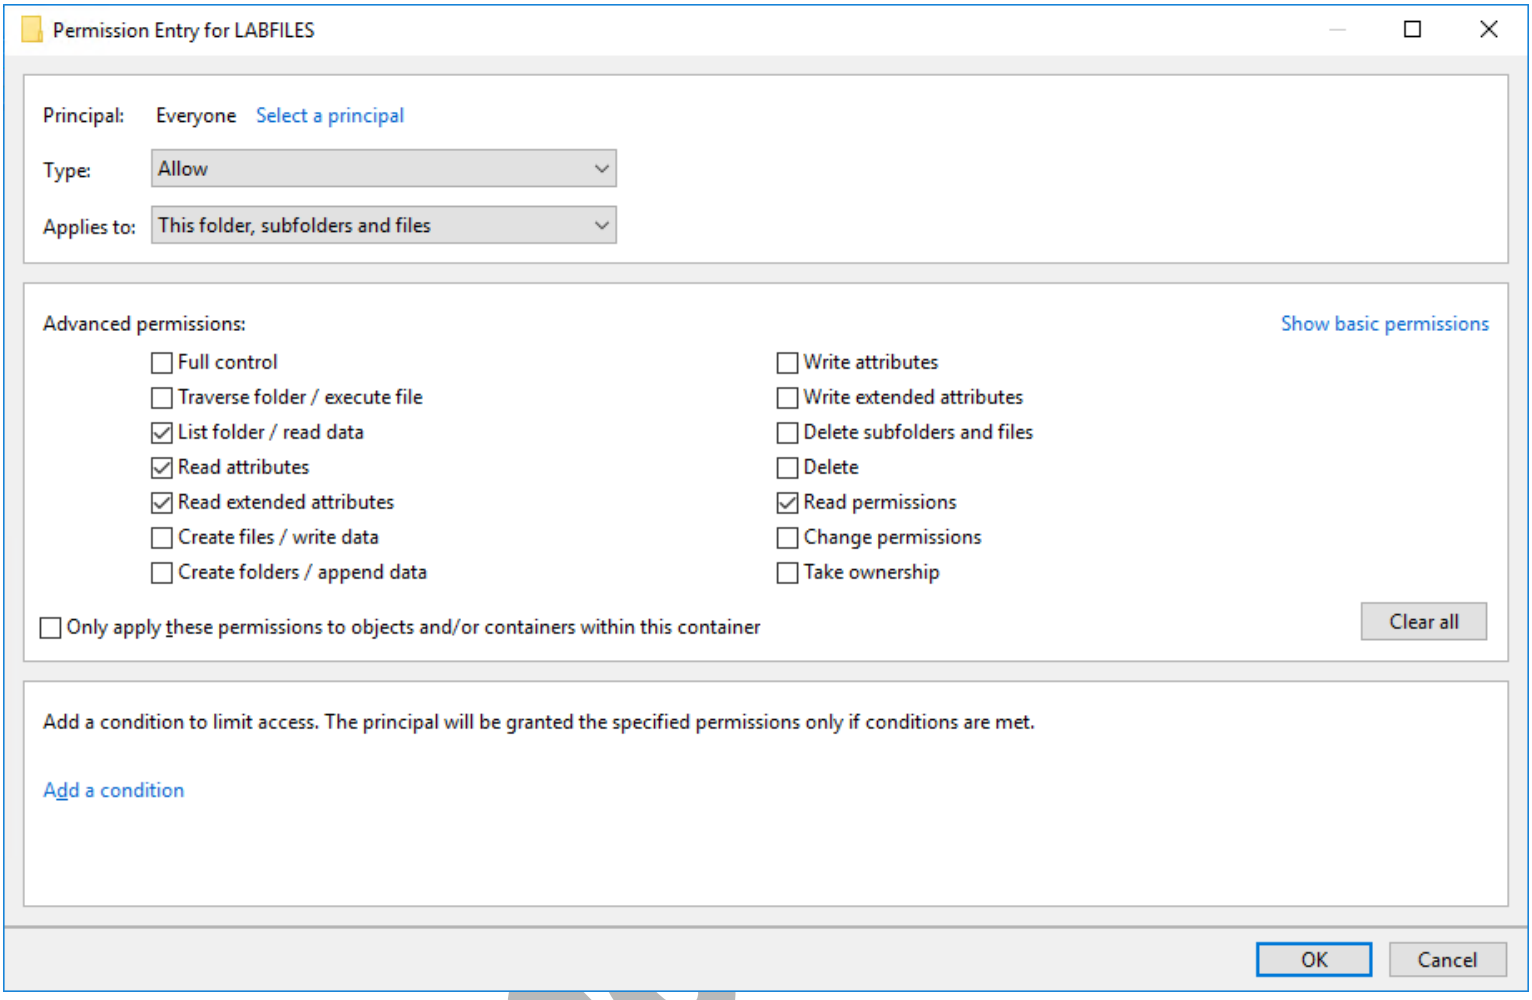
8.2.3 File Permission Facts

This lesson covers the following topics:

- File system permissions
- Managing file system permissions

File System Permissions

With file system security, each object in the file system has an access control list (ACL) associated with it. The ACL contains a list of accounts (principals) allowed to access the resource and the permissions they have over it. The order of ACEs in the ACL is important in determining effective permissions for a given account. ACLs can be enforced by a file system that supports permissions, such as NTFS, ext3/ext4, or ZFS.



Configuring an access control entry for a folder. (Screenshot used with permission from Microsoft.)

For example, in Linux, there are three basic permissions:

Read (r) - is the ability to access and view the contents of a file or list the contents of a directory.

Write (w) - is the ability to save changes to a file or create, rename, and delete files in a directory (also requires execute).

Execute (x) - is the ability to run a script, program, or other software file, or the ability to access a directory, execute a file from that directory, or perform a task on that directory, such as file search.

These permissions can be applied in the context of the owner user (u), a group account (g), and all other users/world (o). A permission string lists the permissions granted in each of these contexts:

drwxr-xr-xhome

The string above shows that for the directory (d), the owner has read, write, and execute permissions, while the group context and other users have read and execute permissions.

The **chmod** command is used to modify permissions. It can be used in symbolic mode or absolute mode. In symbolic mode, the command works as follows:

chmod g+w, o-xhome

The effect of this command is to append write permission to the group context and remove execute permission from the other context. By contrast, the command can also be used to replace existing permissions. For example, the following command applies the configuration shown in the first permission string:

chmod u=rwx,g=rx,o=rxhome

In absolute mode, permissions are assigned using octal notation, where r=4, w=2, and x=1. For example, the following command has the same effect:

chmod 755home

In this example, the 755 correlates to the permissions assigned to the user, group, and others, where user permissions are represented by 7, group permissions are 5, and others are also 5. The numbers are generated by adding the values associated with r (read), w (write), and x (execute). The only combination of values that can result in 7 is 4+2+1 or r, w, x. Similarly, the only combination of values resulting in 5 is 4+1, or r,x. This means the owner has r,w, and x, whereas the group and others have only r and x.

Managing File System Permissions

On a Windows system, access to files is controlled through two sets of permissions: share and New Technology File System (NTFS). The following table describes permissions specific to each type.

Permission Type	Description
Share	Share permissions control access through a network connection with the file server. If files are accessed locally, share permissions do not control access. Share permissions have three levels of permissions: Reader (read-only) Contributor (read and write) Owner or Co-owner (full control or all permissions) Share permissions can be set only on a folder.
NTFS	NTFS permissions: Can be set on drives, folders, and files. Control both local and network access.

Permission Type	Description
	Have dozens of permissions that offer granular control over what actions are allowed. Can be set only on volumes formatted with NTFS.

Be aware that:

- Both share and NTFS permissions use a discretionary access control list (DACL) for controlling access. The access list identifies the users or groups and their associated permissions to files or folders.
- Both share and NTFS permissions include Allow or Deny permissions. Deny permissions override Allow permissions.
- Both share and NTFS permissions must be configured to allow access through the share. If a user is allowed share access but no NTFS permissions are set for the user or a group to which the user belongs, no access will be allowed.
- Effective permissions to shared folders are the more restrictive of either share or NTFS permissions.
- A user's effective permissions cannot be greater than the share permissions assigned to the user or a group to which the user belongs. For this reason, a common strategy for combining share and NTFS permissions is to:
  - Assign Co-owner share permissions to Everyone.
  - Use NTFS permissions to control access. Use the principle of least privilege by assigning NTFS permissions only to necessary groups and by assigning only the necessary permissions to those groups. Even though Everyone has share permissions, only the users or groups with NTFS permissions will have access.
- Permissions for folders and files can be inherited. On Windows systems, the Advanced Security settings identify when permission inheritance is in effect.
- Whenever possible, assign permissions to groups rather than users. Users receive the permissions assigned to their groups.

8.2.4 Configuring NTFS Permissions (Demo Video)

Transcript:

In this demonstration, we're going to work with NTFS and share permissions. Since these two permissions overlap, it's important to understand how they relate to each other. I'm on two different machines here. On one machine, I'm logged in as the TestOut user. On the other, I'm logged in as the jdoe user.

We're going to share from this machine. I'll go to File Explorer > This PC > C: > Research. Now I'll right-click and select Properties > Sharing. You can see that this folder is currently shared on the network. I'll click on the Share button. Currently, only the TestOut user has rights to access the share—both Read and Write access. Let's close this.
Let's go to our Security tab, which houses our NTFS file system permissions. Currently, the System group, the TestOut user, and the Administrators group have NTFS permissions to the Research folder. The jdoe user—which is the user currently logged in to the other system—doesn't have any access. I'll switch to the other machine and try to connect to

the share. Since I'm logged in as jdoe, those are the credentials that'll be used to try to connect to the Research folder. When I browse to it and click on it, it pops up and explains that I don't have permission to access this folder.
Let's go back to the first machine and change it so the jdoe user can access the network share. Again, on the Properties page for the Research folder, I need to add permissions for jdoe. I'll change the Permission Level to Read/Write and then click Share.
Now let's go to our NTFS permissions found on the Security tab and view the jdoe user's permissions. Notice that the jdoe user has been added to the NTFS permissions automatically when we added the user to the share. As you can see, jdoe has Full control over files on this share. So, both share and NTFS permissions have been given to the jdoe user for the Research folder. Let's test from the other machine. Browsing back to the share, instead of an error, the jdoe user has access now.
Now, what happens when your NTFS and share permissions aren't aligned or they conflict with each other? Let's change the settings and see what happens. Back on the Properties page of the Research folder, let's change the NTFS settings so the jdoe user doesn't have the ability to change files. We just click Edit, select the user, and then remove the Full control, Modify, and Write permissions. Then we click OK. Again, switching back to the other machine, I'll open the Research folder and open a file to make changes to it. When I click Save now, it asks me where to save the file because the current location—which is actually on the other machine—isn't allowing me to save changes to the file. I can only save a copy to a different location. So, the jdoe user has permission to change the file as far as the network share is concerned, but the NTFS permissions don't allow any changes.
If you go back in to share rights and give jdoe access to read the files, but you don't change the NTFS rights, you'll have the same problem. It's not that share rights or NTFS rights supersede the other. It's that whichever one is more restrictive will be enforced. So since the NTFS rights are more restrictive here, they supersede all the other rights.
Okay, that's it for this demonstration. In this demo, we talked about configuring share and NTFS permissions. We first looked at how to assign NTFS and share permissions for a folder and for a user account. And we talked about how rights are applied when there's a conflict between the two types of permissions.

8.2.5 Configure NTFS Permissions (Simulation)

Scenario

There are two groups of users who access the CorpFiles server: Marketing and Research.

Each group has a corresponding folder:

D:\Marketing Data

D:\Research Data

In this lab, your task is to:

Disable permissions inheritance for **D:\Marketing Data** and **D:\Research Data** and convert the existing permissions to explicit permissions.

For each of the above folders, remove the **Users** group from the access control list (ACL).

Add the **Marketing** group to the Marketing Data folder ACL.

Add the **Research** group to the Research Data folder ACL.

Assign the groups **Full Control** to their respective folders.

Do not change any other permissions assigned to other users or groups.

Explanation

While completing this lab, use the following:

D:\Marketing Data

D:\Research Data

Groups:

Marketing

Research

Complete this lab as follows:

Open the Data (D:) drive.

From the Windows taskbar, select **File Explorer** .

From the left pane, expand and select **This PC** > **Data (D:)** .

Disable inheritance and convert inherited permissions to explicit permissions.

From the right pane, right-click the applicable ***folder*** and then select **Properties** .

Select the **Security** tab.

Select **Advanced** to modify inherited permissions.

Select **Disable inheritance** to prevent inherited permissions.

Select **Convert inherited permissions into explicit permissions on this object** .

Remove the Users group from the access control list.

Under *Permission entries* , select **Users** .

Select **Remove** to remove the group from the access control list.

Select **OK** .

Add a new group to the access control list and allow Full Control.

From the Properties dialog, select **Edit** to add a group to the access control list.

Select **Add** .

Enter the ***name*** of the group you want to add and then select **Check Names** .

Select **OK** .

With the newly added group selected, under the Allow column, select **Full control** and then select **OK** .

Select **OK** to close the properties dialog.

Repeat steps 2 - 4 to modify the permissions for the additional folder.

8.2.6 Disable Inheritance (Simulation)

Scenario

Confidential personnel data is stored on the CorpFiles file server in a shared directory named Personnel. You need to configure NTFS permissions for this folder so that only managers are authorized to access it.

In this lab, your task is to perform the following:

Grant the Managers group the **Full Control** permission to the **D:\Personnel** folder.

Remove all inherited permissions that are flowing to the **D:\Personnel** folder.

If a permission appears grayed out, it is an inherited permission. To modify it, you need to disable inheritance and create explicit permissions.

Explanation

Complete this lab as follows:

Open the **Data (D:)** drive.

From the Windows taskbar, select **File Explorer** .

From the left pane, expand and select **This PC** > **Data (D:)** .

Configure NTFS permissions.

From the right pane, right-click **Personnel** and select **Properties** .

Select the **Security** tab.

Select **Edit** .

Select **Add** .

Enter **Managers** as the group that will receive permission to the folder.

Select **OK** .

With the Managers group selected, select the appropriate **Full control** .

Select **OK** .

Prevent inherited permissions from parent.

From the Security tab, select **Advanced** .

Select **Disable inheritance** .

Select **Remove all inherited permissions from this object** .

Select **OK** to close the Advanced Security Settings for Personnel dialog.

Select **OK** to close the Properties dialog.

8.2.7 Practice Questions (Section Quiz)

q_file_sys_sec_dmz_secp8

You have placed a File Transfer Protocol (FTP) server in your DMZ behind your firewall. The FTP server will distribute software updates and demonstration versions of your products. However, users report that they are unable to access the FTP server.

What should you do to enable access?

Answers:

Install a VPN.

Define user accounts for all external visitors.

***Open ports 20 and 21 for outbound connections.**

Move the FTP outside of the firewall.

Explanation:

To allow FTP traffic into your DMZ, you must open the correct ports on the firewall. For FTP, the correct ports are 20 and 21 for outbound connections.

Installing a VPN is not necessary to grant access to external users.

Defining user accounts may be required in some situations, but this scenario requires anonymous access.

Moving the FTP server outside the firewall is not a secure action.

q_file_sys_sec_ftps_secp8

FTPS uses which mechanism to provide security for authentication and data transfer?

Answers:

IPsec

Token devices

Multi-factor authentication

***SSL**

Explanation:

File Transfer Protocol Secure (FTPS) uses Secure Sockets Layer (SSL) to provide security for authentication and data transfer. FTPS is an FTP replacement that brings reasonable security to an otherwise unsecured file transfer mechanism. FTP by itself is unsecured because FTP transmits logon credentials in cleartext and does not encrypt transmitted files.

The following are protocols that are not designed to provide a mechanism to provide secure authentication and data transfer for FTPS:

IPsec - IPsec is a protocol suite for encrypting network communications.

Token devices - A token is a device that employs an encrypted key for which the encryption algorithm - Ã‚Â• the method of generating an encrypted password - Ã‚Â• is known to a network's authentication server.

Multi-factor authentication - Multi-factor authentication (MFA) is a multi-step account login process that requires users to enter more information than just a password.

q_file_sys_sec_ftp_secp8

To transfer files to your company's internal network from home, you use FTP. The administrator has recently implemented a firewall at the network perimeter and disabled as many ports as possible.

Now, you can no longer make the FTP connection. You suspect the firewall is causing the issue.

Which ports need to remain open so you can still transfer the files? (Select two.)

Answers:

443

80

23

***21**

***20**

Explanation:

FTP uses port 21 for connection requests and port 20 for data transfers. Both ports need to remain open for you to transfer files to your company's internal network from home.

Telnet uses port 23, SSL uses port 443, and HTTP uses port 80.

q_file_sys_sec_issuing_assets_secp8

You are the IT manager at a rapidly growing start-up. A new employee has just been hired, and you are responsible for provisioning a user account for the employee. The employee's role involves graphic design, and they will be working remotely.

Which of the following steps is MOST crucial to ensure the employee can effectively perform their duties?

Answers:

Conducting a thorough background check.

Enrolling the employee in a security awareness training program.

***Issuing the employee the necessary hardware and software assets.**

Setting up a VPN for the employee to securely access the company network.

Explanation:

Issuing the employee the necessary hardware and software assets is the most crucial step in this scenario. As a graphic designer, the employee will need specific tools to perform their job. Without these, the employee will be unable to work effectively, regardless of the other provisions in place.

Conducting a thorough background check is an important step in the hiring process and can help ensure the security of the company. However, it is not directly related to the employee's ability to perform her duties as a graphic designer.

Enrolling the employee in a security awareness training program is a good practice and can help protect the company's information. However, without the necessary hardware and software, the employee will not be able to perform their job, regardless of their security awareness.

Setting up a VPN for the employee to securely access the company network is important for security, especially as the employee will be working remotely. However, without the necessary hardware and software, secure access to the company network will not enable the employee to perform their job.

q_file_sys_sec_netbios_secp8

You want to close all ports associated with NetBIOS on your network's firewalls to prevent attacks directed against NetBIOS.

Which ports should you close?

Answers:

67, 68

***135, 137-139**

161, 162

389, 636

Explanation:

NetBIOS uses the following ports:

TCP 135

TCP and UDP 137

TCP and UDP 138

TCP 139

Dynamic Host Configuration Protocol (DHCP) uses ports 67 and 68. Simple Network Management Protocol (SNMP) uses ports 161 and 162. Lightweight Directory Access Protocol (LDAP) uses ports 389 and 636.

q_file_sys_sec_sftp_secp8

A university's IT team must securely transfer large files containing sensitive financial data between two offices in different cities.

Which protocol would be the MOST suitable and secure option for this file transfer?

Answers:

HTTP

FTP

SMTP

***SFTP**

Explanation:

Secure File Transfer Protocol (SFTP) is a secure and encrypted version of File Transfer Protocol (FTP), making it the most suitable and secure option for transferring sensitive financial data between offices. SFTP ensures the confidentiality and integrity of the data during transit.

Hypertext Transfer Protocol (HTTP) is not a secure file transfer protocol, and it transmits data in clear text, which exposes sensitive financial data to potential interception and compromise.

FTP is not secure as it does not use encryption, thus making it unsuitable for transferring sensitive financial data securely.

Simple Mail Transfer Protocol (SMTP) sends and receives emails and is not for secure file transfers.

q_file_sys_sec_shared_folders_secp8

As a senior IT professional, you are tasked with securing your company's file system. The company has a large number of employees who need to access various files and documents for their work.

Which of the following strategies would be the MOST effective in ensuring both security and accessibility of the file system?

Answers:

Implement full-disk encryption on all company computers.

Use a VPN for all data transfers within the company.

***Create shared folders with appropriate access permissions.**

Disable all unused services on company computers.

Explanation:

Creating shared folders with appropriate access permissions is the most effective strategy in this scenario. This allows employees to access the files they need while still maintaining security. Access permissions can be set according to the principle of least privilege, ensuring that employees only have access to the files they need for their work.

Implementing full-disk encryption on all company computers is a good security measure, but it does not directly address the issue of file accessibility for employees. It also may not be necessary for all computers, especially if they do not store sensitive information.

Using a VPN for all data transfers within the company can help secure data in transit, but it does not directly address the issue of file accessibility. Additionally, it might slow down the network and make file access more difficult for employees.

Disabling all unused services on company computers can help reduce potential attack vectors, but it does not directly address the issue of file accessibility. It is a good security practice but does not solve the problem presented in the scenario.

q_file_sys_sec_ssh_secp8

Which of the following file transfer protocols uses SSH to provide confidentiality during the transfer? (Select two.)

Answers:

FTPS

HTTPS

***SCP**

***SFTP**

FTP

Explanation:

Secure Copy Protocol (SCP) and SSH File Transfer Protocol (SFTP) both use SSH to provide confidentiality.

FTPS and HTTPS both use Transport Layer Security (TLS) or Secure Sockets Layer (SSL) to provide confidentiality.

File Transfer Protocol (FTP) is an older TCP/IP protocol that's used for transferring files across systems.

q_file_sys_sec_temporary_privileges_secp8

You are the IT Security Manager at a large corporation. A team of external auditors has been hired to conduct a comprehensive audit of your company's financial systems. They need temporary access to sensitive data and systems.

Which of the following is the MOST appropriate way to handle this situation?

Answers:

Grant the auditors unrestricted access to all systems for the duration of the audit.

***Create new user accounts for the auditors with temporary elevated privileges.**

Grant the auditors the same access level as the company's financial team.

Deny the auditors access to the systems and provide them with printed reports instead.

Explanation:

Creating new user accounts for the auditors with temporary elevated privileges is the most appropriate action. This allows the auditors to access the necessary systems and data while maintaining control over their access levels. Once the audit is complete, these temporary accounts can be deactivated, ensuring no unnecessary access remains.

Granting the auditors unrestricted access to all systems for the duration of the audit is not a good practice. This could expose sensitive data and systems to unnecessary risk. The principle of least privilege should always be applied, even in temporary situations.

Granting the auditors the same access level as the company's financial team may not be appropriate. The auditors may need access to different systems or data than the financial team, and this approach does not take into account the temporary nature of their need for access.

Denying the auditors access to the systems and providing them with printed reports instead is not practical or efficient. It may also hinder the auditors' ability to conduct a thorough and accurate audit.

q_fileperms_acl_secp8

You have a shared folder named Reports. Members of the Managers group have been given write access to the shared folder.

Mark Mangum is a member of the Managers group. He needs access to the files in the Reports folder, but he should not have any access to the Confidential.xls file.

What should you do?

Answers:

Remove Mark Mangum from the Managers group.

***Add Mark Mangum to the ACL for the Confidential.xls file with Deny permissions.**

Configure NTFS permissions for Confidential.xls to allow read-only.

Add Mark Mangum to the ACL for the Reports directory with Deny permissions.

Explanation:

To prevent Mark from accessing one file, edit the ACL for that file, add his user account to the ACL, and configure Deny permissions. The Deny permissions configured on the file override the Write permissions granted to the folder through the group.

Removing Mark from the group would prevent access to the entire folder, not just to the one file.

Configuring deny permissions to the folder for Mark would also prevent access to the entire folder.

q_fileperms_chmod_secp8

You are a system administrator for a Linux server. You have a directory named "project," which contains sensitive data. The directory is currently accessible to everyone in your team.

You need to change the permissions so that only you (the owner) can read, write, and execute, while your team (the group) can only read and execute. Other users should not have any access.

Which of the following commands should you use?

Answers:

chmod 755 project

***chmod 750 project**

chmod 700 project

chmod 777 project

Explanation:

The **chmod 750 project** command is the correct answer. This command gives read, write, and execute permissions to the owner, read and execute permissions to the group, and no permissions to others. This is the desired outcome.

The **chmod 755 project** command is incorrect. This command gives read, write, and execute permissions to the owner and read and execute permissions to the group and others. This is not the desired outcome, as others should not have any access.

The **chmod 700 project** command is incorrect. This command gives read, write, and execute permissions to the owner and no permissions to the group and others. This is not the desired outcome, as the group should have read and execute permissions.

The **chmod 777** project command is incorrect. This command gives read, write, and execute permissions to the owner, the group, and others. This is not the desired outcome, as others should not have any access, and the group should not have write permissions.

q_fileperms_dacl_secp8

You want to give all managers the ability to view and edit a certain file. To do so, you need to edit the discretionary access control list (DACL) associated with the file. You want to be able to easily add and remove managers as their job positions change.

What is the BEST way to accomplish this?

Answers:

***Create a security group for the managers. Add all users as members of the group. Add the group to the file's DACL.**

Add each user account to the file's DACL.

Create a distribution group for the managers. Add all users as members of the group. Add the group to the file's DACL.

Add one manager to the DACL that grants all permissions. Have this user add other managers as required.

Explanation:

Create a security group for the users and add the users to the DACL. A group is an object that identifies a set of users with similar access needs. Microsoft systems have two kinds of groups, which are distribution groups and security groups. Only security groups can be used for controlling access to objects. As manager roles change, add or remove user accounts from the group. Assigning permissions to a group grants those same permissions to all members of the group.

Adding individual user accounts instead of groups to the ACL would require more work as you add or remove managers.

q_fileperms_ntfs_permissions_secp8

A company employee, Jane, is unable to access a shared folder on the company's file server.

The IT department has confirmed that Jane has been granted "Contributor" share permissions for this folder. However, Jane is still unable to access the folder. As a network administrator, you are tasked with troubleshooting this issue.

Which of the following steps would you take first to resolve this problem?

Answers:

***Check if the folder has NTFS permissions set for Jane or a group she belongs to.**

Change Jane's share permissions to "Owner."

Reformat the volume with NTFS.

Assign "Co-owner" share permissions to Everyone.

Explanation:

Checking if the folder has NTFS permissions set for Jane or a group she belongs to is the correct first step. Even if Jane has been granted share permissions, she will not be able to access the folder if no NTFS permissions have been set for her or a group she belongs to. Checking this should be the first step in troubleshooting.

Changing Jane's share permissions to "Owner" would not necessarily resolve the issue if the problem lies with the NTFS permissions. This could potentially give Jane more access than necessary, violating the principle of least privilege.

Reformatting the volume with NTFS is unnecessary and could lead to data loss. The problem is not with the file system itself but with the permissions set within it.

Assigning "Co-owner" share permissions to Everyone is not a good first step. This would potentially give all users full control over the shared folder, which could lead to security risks. It's better to troubleshoot the specific permissions issue first.

q_fileperms_ntfs_secp8

If Mark has a read-write permission to the share \\fileserver\securefiles and a read-only permission to the file coolstuff.docx on the NTFS file system shared by the file share, he is able to perform which action?

Answers:

Delete the file.

***Read the file.**

Rename the file.

Change the contents of the file.

Explanation:

The permissions of the share and file system work together, and the more restrictive of the two is used when accessing the file through the share. In this case, Mark is allowed to read the file.

Because the NTFS permissions are set to read-only, he would not be allowed to delete, rename, or change the file.

q_fileperms_permissions_secp8

You have a file server named Srv3 that holds files used by the development department. You want to allow users to access the files over the network and control access to files accessed through the network or a local logon.

Which solution should you implement?

Answers:

***NTFS permissions and share permissions**

NTFS permissions and file screens

Share permissions and quotas

Share permissions and file screens

Explanation:

Use New Technology File System (NTFS) permissions and share permissions to control access to files. Share permissions apply when files are accessed through the network, and NTFS permissions apply to both network and local access.

Use file screens to restrict the types of files that can be saved within a folder.

8.3 Linux Host Security

As you study this section, answer the following questions:

How do you check for unnecessary network services on a Linux system?

Why is it important to identify open ports? What utility can identify open ports?

Which utility can identify network statistics on a system?

Which commands should you use to disable unneeded daemons?

What are iptables?

In this section, you will learn to:

Remove unnecessary services.

Install and update iptables.

Key terms for this section include the following:

Term	Definition
iptables	iptables is a firewall command line utility for Linux operation systems that uses three policy chains to allow or block network traffic.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.2 Explain common threat vectors and attack surfaces. Removable device 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Patching Hardening techniques Host-based firewall Host-based intrusion prevention system (HIPS) Disabling ports/protocols Removal of unnecessary software
TestOut Security Pro	2.1 Harden physical access 2.1.3 Install and configure a firewall

8.3.1 Linux Host Security (Lesson Video)

Transcript:

The Linux operating system is widely used and preferred in the security community. Just like its Windows counterpart, though, Linux is vulnerable to attacks. By default, the Linux OS is designed to reduce vulnerability and attack surface, but attackers are still able to exploit known vulnerabilities. There's only one way to eliminate all potential threats and that's to disconnect from the internet. Unfortunately, this isn't an option for most users.

With that in mind, you should remain vigilant and take the necessary precautions to protect your system. In this lesson, we'll discuss how to minimize your Linux system's attack surface with simple yet effective methods for reducing the chances of an attack.

The first step is to lessen your system's attack surface as a whole. The more services that are loaded and active on a system, the more opportunities exist for attack. Many services utilize a specific TCP/IP port that's exposed to the network. Services such as DNS, FTP, SNMP, and others may or may not be required on your system. If not, these services should be unloaded and deactivated.

Different Linux distributions load various programs and daemons, and certain programs and daemons are necessary dependencies of others. So make sure you understand your system's requirements before you attempt to unload and deactivate anything. To see a list of all loaded and active services, you can use the â€˜systemctl' command, as shown here. When used, both the service name and description are displayed. Additionally, you can add the â€˜list-dependencies' statement to display a dependency services tree. With this information, you can discover potentially unneeded services and unload them. You first stop the service and then disable it from starting automatically.

A word of cautionâ€”do your research! Don't simply unload a service without knowing what it's used for. It may be a system service or a service that something else depends on. Look up the name in a search engine, or use the â€˜man' or â€˜info' utilities to find out what it's used for. Only then, if you determine it's unneeded, should you stop and disable the service.

It may be necessary to have ports open for a Linux system to work properly. For example, if a server provides DHCP or DNS services or web content, TCP/IP ports must be open to allow everything to work. One way to discover open ports on a system is to use the Nmap utility.

Nmap is a tool that's either bundled with Linux distributions or can be installed using apt or yum. When used appropriately, this tool can provide you with very useful information about a given system or network. When used inappropriately, attackers can take control and perform reconnaissance. For our purposes, we can use Nmap to show us our system's open ports.

Often, open ports are indications that a service is running on the system that controls that port. If we see a port open that shouldn't be, it can tell us that a service is running on the system that we probably don't need. We can check the system and stop and disable the service if needed.

In the example here, Nmap shows the default gateway's open ports. There may be ports we expect and others we don't. For example, here we see that port 80 is open with the service http. If this machine doesn't require web services, we may want to close that port by stopping the web server. If we see an unexpected open port, we need to find the service that's opening that port to determine whether the service is necessary or not. If it isn't, we can stop and disable the service to close the port. Just use this tool with caution. Since Nmap is widely used by hackers, running it may trigger alarms and alerts.

There are many command line parameters available with Nmap that let us customize the desired command output. Let's discuss a few. The â€˜â€“sU' and â€˜â€“sT' parameters display only UDP and TCP ports. Keep in mind that these parameters might make your scan take an extraordinarily long time. Use â€˜-6' to choose IPv6 scanning. To enable OS detection, use â€˜-A' or
â€˜â€“O'. We use the â€˜-p' parameter to specify a range, while the â€˜-sn' parameter enables a ping-only scan to determine if a host is up without having to perform a port scan.

Netstat is another Linux or Windows tool that we can use to scan for open ports. In this example, a Linux machine was used to display open ports on a system with IPv4. I used the â€˜â€“l' option to view a list of listening sockets and the â€˜4' option to show only IPv4 addresses on the Linux host.

Here you see I have a socket open for ssh. Also, the system is running NTP. These are TCP/IP ports that are well known as ports 22 and 123, respectively. By using this output, I can also see what else is running on the system.

We can customize the Netstat utility to provide us with only the information we're specifically looking for. As with Nmap, the Netstat utility has several command line parameters. For example:

â€˜-a' lists all listening and non-listening sockets.
â€˜-I' displays statistics for all your network interfaces.
â€˜-l' displays just listening sockets or sockets that are open for listening.
â€˜-s' displays summary information for each protocol enabled on the system.
â€˜-r' shows your routing table.

Keep in mind that these options may vary in availability depending on whether we're using the Linux version of Netstat or the Windows version.

In addition to unloading unneeded services, you also need to make sure that your Linux operating system remains current by installing operating system and program updates. For example, as software is released, it's usually not perfect and free of defects. Defects can take the form of logic errors in which a program doesn't calculate or apply input correctly. There could be something wrong with a screen display as well. In addition, vulnerabilities can be introduced

that would allow threat actors to compromise your system. Often, these defects are found only after software has been released. So once the software is in use and the defects are found and corrected, it's important that you update your software immediately.

You can manually update the packages on your system using package managers such as yum or apt. The one you use will depend on which distribution you're using. These processes scour the repository and search for newer updates and patches. If a single package requires an update, the package name can be specified to check if that package requires an update. Most often, though, it's a good practice to update all available package updates. For example, if you're running a Red Hat variant, such as CentOS or Fedora, run the â€˜yum update' command, as shown here. In this example, you see that only a single packageâ€”libexifâ€”needs an update.

When you use a Debian variant like Ubuntu or Mint, you first run the â€˜apt update' command. This refreshes the repository information. After that, you run â€˜apt upgrade' to perform the manual update process. Notice that in this case, there are 28 packages to be upgraded. An exception to utilizing apt or yum is with SuSE Linux. SuSE Linux uses a different package manager called zypper. The syntax for the command is similar to apt and yum and accomplishes the same tasks.

The last topic for enabling Linux host security is to ensure a host-based firewall is running on your Linux system. One philosophy of computer security is to utilize a layered approach. Most systems are protected first by a network firewall. If anything does happen to get through, threat actors also have to contend with the host system's firewall as well. Most, if not all, Linux systems are distributed with host-firewall software. This software is known as firewalld.

In some instances, there might even be a series of firewalls that are specific to protecting certain network aspects. These together form a solid barrier to attackers. But nothing is foolproof and adding another layer of protection is always a good idea. The Linux host-based firewall adds additional protection from outside entities, and it can also protect the system from insider threats, too.

A host-based firewall acts like a gatekeeper between your system and the external and internal network. This firewall monitors all traffic that flows in both directions between the computer and network. You configure this firewall with a list of rules called access control lists, or ACLs. These rules define what is and isn't allowed to pass through. Several Linux distributions use the firewalld daemon to implement host-based firewalls. Other distributions might use a different package, so check your distribution vendor to see which one to use.

First, make sure firewalld has been installed on your system. You can use the â€˜yum' or â€˜apt' command lines to check whether it has, as shown here. If those commands return a value, you know firewalld has been installed and you can begin configuring it. If you get a blank message or one stating firewalld could not be found, you'll need to download and install it. This can also be done using the â€˜yum' or â€˜apt' commands. Know that firewalld depends on the Python programming language. If not already installed, just note that the installer will also install the needed Python dependencies on your system.

If firewalld is already installed or if you just installed it, you need to ensure it's running and active with the â€˜systemctl' command shown here. It might not be running, and you might see inactive or dead as the status. If that's the case, you can start the daemon by issuing the â€˜systemctl start firewalld' command. Checking the status again should show the daemon running.

With the firewall running, there are several different commands that you can use to manage it.

We use the â€˜firewall-cmd' command and add parameters to control how the firewall operates and is configured. A sampling of the commands are listed here. Run the â€˜firewall-cmd --state' command to check the firewall's status. You can also run â€˜firewall-cmd --get-active-zones' to display the default firewall zone configuration.

This particular firewall package comes with several predefined firewall zones that you can use, starting at extremely secure to not very secure at all. Predefined zones include Home, External, Work, and Trusted. The default zone most distributions predefine is Public, but you can actually pick whichever one you want to use.

Once you have the firewall running and a default zone set up, there may be situations in which you need to open a particular firewall port to support a particular service. For example, if the system is set up as a web server, you must let web traffic through. If you don't configure firewall exceptions, the web traffic will be blocked.

Web servers typically use ports 80 and 443 or HTTP and HTTPS for web traffic. We need to allow these ports to remain open so that the web server is reachable. To do this, we need to allow the right ports and protocols through the firewall. To enable web services, we open ports on the firewall. To open ports, we add them to the exception list on the firewall itself.

This is also done using the â€˜firewall-cmd' command. For example, we first use the â€˜--permanent' parameter to store the exception in the database so that it remains persistent even if the computer is restarted. Next, we need to define which zone we're using and then the port we want open.

It's also possible to use the protocol rather than the port number when placing exceptions into the firewall. We place the exception in the firewalld configuration with HTTPS by using the same command but substituting the protocol. The last thing we need to do is restart the firewall or reload the configuration. If the system is in use and we don't want to disrupt

it, we enter the â€˜reload' command, which allows the firewall daemon to continue running. The new configuration is loaded and activated for us in the background.
The last thing we need to do is restart or reload the newly configured firewall. This allows us to use these changes immediately without rebooting the system. The â€˜reload' parameter leaves the firewall activated.
That's it for this lesson. In this lesson, we discussed some procedures to keep a Linux host safer from attacks. We discussed removing unneeded services from your system and using Nmap and Netstat to identify running services. We also discussed how keeping the system current with OS and program updates is important. Finally, we ended by discussing the benefits of implementing the host-based firewall called firewalld.

8.3.2 Removing Unnecessary Services (Demo Video)

Transcript:

It's important to know many things about services: how to start them, see if they're running, stop them, restart them, enable them, and disable them. For this demo, we're going to work with an Ubuntu Linux system and practice working with some services.

I'm already logged on to the system, and I'll start the terminal. I have a shortcut here, but you can also go here, to Show Applications, and then search for 'terminal' in the search box.
I want to see the init.d directory. We're interested in services that are running. Let's go to the directory by typing 'cd /etc/init.d/'. Press Enter. Now I'll do an 'ls' to see what's in this directory.
All right, here are my services. Here, I have Apache server. Here, I have mysql. Over here, we have ssh. And down here, there's FTP. On this system, there's no reason to have FTP running, so let's see how we can stop it.
I'll type 'cd' to get back to root and 'clear' to clean up my screen.
So far, I've used init.d to view the services. To manage the services, I'm going to use the systemctl command. Using init.d scripts to manage services isn't possible on newer systems anymore, but I still use it to view services sometimes.
Let's look at my FTP server. First, I want to see its status. So, let's type 'sudo systemctl status vsftpd' and press Enter. It says it's enabled, but it's currently stopped.
I'm going to use my up arrow to get to the last command, change it from status to 'start', and press Enter. Now I'll arrow up until I see status and press Enter again.
I can see that it's running along with some statistics, such as how long it's been up. I can also see the process ID, or PID, right here. Let's clear the screen.
Now I'm going to use my up arrow to go back to my last command. I'm going to backspace here, get rid of the word "start:", and type in 'stop' to stop the FTP service.
I'll arrow up again until I get to status and press Enter. Now you can see that the process has stopped. I'll press Ctrl+C to exit this command and then type 'clear'.
Now I might say, oops, that's not what I wanted to do! It's okay. We'll just arrow up again until we get to start. Press Enter, and everything's just fine again.
What if I made changes to my FTP server, and I need to restart the service? I can just do a restart. Let's up arrow to the last command, backspace here, type in 'restart', and press Enter. Arrow up to the last command, backspace, and change this to 'status'. Press Enter, and you can see my service restarted. I'll clear the screen again.
So far, we've stopped and started our FTP service. But what if I want to have it start at system startup? Or, perhaps, not start when the system starts up?
First, let's see if the service is enabled or not. I can do that with the is-enabled command. I'll arrow up to the last command and change this part to 'is-enabled'. Press Enter, and right here, it says that it's enabled.
What if you want to have your service start every time your system starts? You can do that by changing this to 'enable' and pressing Enter. Now you can see the status is enabled.
If I don't want the service to start, I'll arrow up and change this to 'disable'. Press Enter, and that'll tell this system not to start FTP at startup. I'll arrow up and change this to 'status', and you can see that, up here, it says "disabled", so when the system boots, FTP won't start. Note that the service is still running at the moment because all we did was keep it from running at startup; we didn't stop it from running at this moment.
That's it for this demo. In this demo, we worked with system services. First, we viewed the services to see what was on our system. Then we practiced stopping, starting, enabling, and disabling services.

8.3.3 Linux Host Security Facts

This lesson covers the following topics:

- Protecting ports
- Host-based firewalls and IPS
- Hardening a Linux system

Protecting Ports

Physical device port hardening involves restricting the physical interfaces on a device that can be used to connect to it, thereby reducing potential avenues of physical attack. One common technique is disabling unnecessary physical ports such as USB, HDMI, or serial ports when they serve no business purpose. Doing so helps prevent unauthorized data transfer, installation of malicious software, or direct access to a system.

Port control software provides additional protection by only allowing authorized devices to connect via physical ports based on device identifiers. For instance, it might block all USB mass storage devices except company-approved ones.

Security analysts can leverage settings in device firmware or UEFI/BIOS for port hardening to disable physical ports or to require a password before a device can boot from a nonstandard source like a USB drive. For devices such as tablets and laptops that depend upon wireless protocols, disabling the automatic network connection feature can prevent the device from using potentially insecure or rogue networks.

As revealed by researcher Karsten Nohl in his BadUSB paper (https://assets.website-files.com/6098eeb4f4b0288367fbb639/62bc77c194c4e0fe8fc5e4b5_SRLabs-BadUSB-BlackHat-v1.pdf), exploiting the firmware of external storage devices, such as USB flash drives and even standard-looking device charging cables, presents adversaries with an incredible toolkit. The firmware can be reprogrammed to make the device look like another device class, such as a keyboard. In this case , it could then be used to inject a series of keystrokes upon an attachment or work as a keylogger. The device could also be programmed to act like a network device and corrupt name resolution, redirecting the user to malicious websites.

Another example is the O.MG cable (theverge.com/2019/8/15/20807854/apple-mac-lightning-cable-hack-mike-grover-mg-omg-cables-defcon-cybersecurity), which packs enough processing capability into an ordinary-looking USB-Lightning cable to run an access point and keylogger.

A modified device may have visual clues that distinguish it from a mass-manufactured thumb drive or cable, but these may be difficult to spot. You should warn users of the risks and repeat the advice to never attach devices of unknown provenance to their computers and smartphones. If you suspect a device is an attack vector, observe a sandboxed lab system (sometimes referred to as a sheep dip) closely when attaching the device. Look for command prompt windows or processes, such as the command interpreter starting and changes to the registry or other system files.

Not all attacks have to be so esoteric. USB sticks infected with ordinary malware are still incredibly prolific infection vectors. Hosts should always be configured to prevent autorun when USB devices are attached. USB ports can be blocked altogether using most types of host i ntrusion d etection s ystems (HIDS).

Protect logical ports by implementing measures to secure and control access to ports within a computer system or network. Logical ports are software-based communication features that enable data exchange between applications or services. Common examples of logical ports include the well-known ports used by TCP/IP and UDP protocols.

Firewalls protect logical ports by examining network traffic and enforcing security policies to allow or block specific connections based on port numbers, source and destination addresses, and protocols. Service hardening practices ensure that services running on logical ports are hardened against security threats. Examples include keeping software updated and turning off unnecessary services.

Host-Based Firewalls and IPS

Host-based firewalls and intrusion prevention systems (IPS) are vital elements of endpoint hardening, as they provide controls for incoming and outgoing network traffic and are essential for detecting potential attacks. An important technique for using them when hardening endpoints involves implementing default-deny policies to block all traffic unless explicitly allowed. This tactic ensures that only approved services and applications can communicate. Configuring firewalls to block or allow traffic based on port numbers is also critical to minimize entry points for attack. Traffic filtering enables firewalls and IPS to sift through traffic based on parameters like IP addresses, protocols, and services to block malicious traffic or only allow traffic to use secure protocols.

An integral part of IPS is detecting and preventing intrusions by monitoring for known malicious patterns or anomalies in network traffic. Advanced host-based firewalls often include application control features that permit only trusted applications to communicate. The logs generated by host-based firewalls and IPS support rapid detection and response when integrated with other security tools like security information and event management (SIEM) systems.

Hardening a Linux System

The following table describes the general procedures for increasing endpoint security of a Linux system:

Security Task	Procedure
Remove unnecessary software	Unnecessary software occupies disk space and could introduce security flaws. To remove unnecessary software: Enter one of the following commands: **yum list installed** or **dnf list installed** to see installed RPM packages on the computer. **apt** **apt autoremove** automatically removes unused packages **apt list** list all installed packages **dpkg get-selections** to see installed Debian packages on the computer. Research the function of any unrecognized package to determine if it is necessary. Use one of the following commands to uninstall unnecessary packages. **yum erase *packagename*** **dnf remove *packagename*** **apt remove *packagename***

	rpm -e *packagename* **dpkg -r *packagename***
Check for unnecessary network services	Unnecessary network services waste computer resources and increase the system's attack service. To remove unnecessary network services: Find all installed services and determine which are not needed: DNS, SNMP, DHCP, and others. **systemctl --type=service --state=active** Use the **man** command and the internet to research services you do not recognize. If the service is not needed, determine if it is a dependency for another service. Disable the service by using the following command: **systemctl disable *servicename*** Use one of the following commands to stop the script immediately: **systemctl stop *servicename*** Use one of the following commands to remove the script package entirely: **yum erase *packagename*** **dnf remove *packagename*** **apt remove *packagename*** **rpm -e *packagename*** **dpkg -r *packagename***
Locate open ports	Open ports can provide information about which operating system a computer uses. Also, they can provide entry points or information about ways to formulate an attack. To locate open ports: Install the **nmap** utility if it is not already installed. **yum install nmap** **dnf install nmap** **apt -i nmap** Use both of the following commands to scan for open ports:

	nmap -sT *ipaddress|fqdn* scans for TCP ports **nmap -sU** *ipaddress|fqdn* scans for UDP ports Determine which services use the open ports. Disable any unused service using the open ports information. (*Make sure the service used is not a dependency for another service* .) **systemctl disable *servicename*** **systemctl stop *servicename***
Check network connections	Open network connections (open sockets) on a computer create a security risk. A *socket* is an endpoint of a bi-directional communication flow across a computer network. Use the following **netstat** (network statistics) or **ss** (socket statistics) options to identify the open network connections on Linux systems: **-a** lists both listening and non-listening sockets. **-l** (*lowercase 'L'*) lists listening sockets. **-s** displays statistics for each protocol. **-i** displays a table of all network interfaces.

8.3.4 Configure iptables (Demo Video)

Transcript:

In this demo, we're going to look at iptables, the default firewall for Linux systems. You configure iptables from the from the command line. We aren't going to cover everything about iptables because that's a vast subject that goes way beyond the scope of this course, but we are going to introduce the topic.

We know that a firewall is a part of a computer system, or network, that is designed to block unauthorized access while permitting authorized communications to hosts. Let's start by talking about the filtering table. A filter table has three of what's know as chains. The input chain applies rules to packets coming into the system. The forward chain is for packets being routed through the system. And the output chain is for locally generated packets sent out from the system.
Let's look at our iptables. I have a Linux system running here, and I want to open the terminal, or command line. I'll select it. My terminal application is right here. But if it wasn't listed, I could type 'terminal' in the Search box.
iptables is almost always preinstalled on Linux systems. But if it is not, we can run a command to install or update it. If it is installed, running this command won't hurt anything, so let's go ahead and do that now. To install or update iptables, we have to run this as a root user, so we need to use the sudo command. So, let's type in 'sudo apt-get install iptables'. Linux prompts me for my password, so I'll type that in right here. We can see it tells us that iptables is already installed, and I have the latest version. We are good to go here.
The first thing I want to do is see what's currently configured. Remember that Linux is case sensitive, so pay attention to that when you type in commands. I'm going to clear the screen by typing .clear.. Let's type in 'sudo iptables -L'. Notice that the policy is set to Accept for all three chains.
Let's say our Linux system is getting a very large number of ping requests, so we decide to block echo requests. We can do this with iptables. Let's jump over to a Windows 10 workstation. I'm going to ping my Linux system just to be sure they

can communicate. I know that the IP address for the Linux system is 192.168.0.7, so let's type 'ping 192.168.0.7' and press Enter. You can see I get a response. Now let's jump over to our Linux system and block pings.
Okay, I'm back on the Linux system. I'm going to clear the screen again. To block pings, I need to enter the following command: 'sudo iptables -A INPUT -p icmp --icmp-type echo-request -j DROP'. Remember that this is case sensitive. With this command, the -A tells it I want to add a rule, the -p specifies the protocol. There are a whole lot of switches you can use, but we only use a couple here. We also told iptables to drop the request. We also could have told it to reject the request. The difference is that if we drop it, the system responds as if there isn't even a system there. It does nothing except drop the request. Reject, on the other hand, responds with a message saying the destination port is unreachable. That might tell a hacker that there is something there, but it's not replying.
Now let's go back to our Windows 10 workstation once more and try to ping again. I'm going to type .ping 192.168.0.7. and press Enter. You see that I get request timed out messages back, so the rule is working.
That's it for this demo. In this demo, we talked about iptables. We ran the command to install and update iptables. We looked at the iptables default policies and then configured a simple rule to drop ping requests to our Linux system.

8.3.5 Configure iptables Facts

This lesson covers the following topics:

- Chains
- Actions performed
- Example iptables commands

Chains

The Linux iptables firewall utility uses *policy chains* (sets of rules) to allow or block network traffic. When a connection is initiated to your system, iptables looks for a matching rule. If it doesn't find one, it uses the default action in the tables. Be aware that iptables almost always come pre-installed on any Linux distribution.

The filter table in iptables has three chains. The following table describes them.

Chain	Description
Input	This chain controls the behavior of incoming connections. For example, if a user attempts to ping the system, iptables attempts to match the IP address and port to a rule in the input chain.
Forward	This chain is used for packets leaving the system. These are incoming connections that aren't delivered locally. In other words, the traffic is not destined for the router; the router forwards the traffic to the destination device.
Output	This chain is used for outgoing connections. For example, if you ping testout.com, iptables check its output chain to see what the rules are regarding ping and testout.com before allowing or denying the ping request.

Actions Performed

You can accept, drop, or reject the connections. After you define your accept rules, you should create a rule to drop all other traffic to prevent unauthorized access to the system.

Action	Result
Accept	Allows the connection.
Drop	Drops the connection. For example, an IP address in a rule with a drop action pings your system; the request is dropped. No response is sent to the user.
Reject	Rejects the connection but will send a response back. This lets the sender know that the traffic reached a system but was rejected.

Examples iptables Commands

The following table describes commands for iptables. Keep in mind that these are only a few examples; there are many more iptable commands.

Action	Command
List current rules	**sudo iptables -L**
Clear current rules	**sudo iptables -F**
Save iptables changes (Ubuntu)	**sudo /sbin/iptables-save** The command may be different on other Linux systems.
Drop all incoming traffic	**sudo iptables -A INPUT -j DROP**
Block connections from 192.168.0.254	**sudo iptables -A INPUT -s 192.168.0.254 -j DROP**
Block SMTP mail on port 25	**sudo iptables -A OUTPUT -p tcp --dport 25 -j REJECT**
Allow SMTP mail on port 25	**sudo iptables -A INPUT -p tcp --dport 25 -m conntrack --ctstate NEW,ESTABLISHED -j ACCEPT** **sudo iptables -A OUTPUT -p tcp --sport 25 -m conntrack --ctstate ESTABLISHED -j ACCEPT**
Allow HTTP traffic on port 80	**sudo iptables -A INPUT -p tcp --dport 80 -m conntrack --ctstate NEW,ESTABLISHED -j ACCEPT** **sudo iptables -A OUTPUT -p tcp --sport 80 -m conntrack --ctstate ESTABLISHED -j ACCEPT**

	To allow HTTPS, you would use port 443.
Allow HTTP traffic on port Allow HTTPS traffic on port 443	**sudo iptables -A INPUT -p tcp -m multiport --dports 80,443 -m conntrack --ctstate NEW,ESTABLISHED -j ACCEPT** **sudo iptables -A OUTPUT -p tcp -m multiport --dports 80,443 -m conntrack --ctstate ESTABLISHED -j ACCEPT**

8.3.6 Practice Questions (Section Quiz)

q_linux_host_sec_firewalls_secp8

As a network administrator, you are tasked with implementing measures to secure and control access to logical ports within your organization's computer system. You are considering several strategies to accomplish this task.

Which of the following would be the MOST effective method to protect logical ports?

Answers:

Implementing service hardening practices

Using secure protocols for data exchange

***Implementing firewalls**

Regularly updating software

Explanation:

Implementing firewalls is the most effective method for protecting logical ports. They examine network traffic and enforce security policies to allow or block specific connections based on port numbers, source and destination addresses, and protocols. This directly protects the logical ports from unauthorized access and attacks.

While service hardening is an important part of overall security, it primarily focuses on ensuring that services running on logical ports are hardened against security threats. It does not directly protect the logical ports themselves.

Using secure protocols is a good practice to ensure the security of data in transit. However, it does not directly protect the logical ports from unauthorized access or attacks.

Regular software updates are important to fix security vulnerabilities. However, they do not directly protect the logical ports from unauthorized access or attacks.

q_linux_host_sec_ips_solution_secp8

As a cybersecurity analyst, you are tasked with enhancing the endpoint security of your organization's network. You are considering several strategies to accomplish this task.

Which of the following would be the MOST effective method to control incoming and outgoing network traffic and detect potential attacks?

Answers:

***Implementing host-based firewalls and IPS with default-deny policies**

Regularly updating all software and applications

Implementing a strong password policy

Regularly conducting penetration testing

Explanation:

Implementing host-based firewalls and IPS with default-deny policies is the most effective method, as it provides controls for incoming and outgoing network traffic and is essential for detecting potential attacks. Default-deny policies block all traffic unless explicitly allowed, ensuring that only approved services and applications can communicate.

While regularly updating all software and applications is a good practice to fix security vulnerabilities, it does not directly control network traffic or detect potential attacks.

While a strong password policy is important for securing user accounts, it does not directly control network traffic or detect potential attacks.

While penetration testing is important for identifying vulnerabilities in the network, it does not provide real-time control of network traffic or detection of potential attacks.

q_linux_host_sec_netstat_secp8

Which command should you use to display listening and non-listening sockets on your Linux system? (Tip: enter the command as if in Command Prompt.)

Answers:

netstat -a

netstat -a

Explanation:

Use **netstat -a** to identify listening and non-listening sockets on a Linux system. A socket is an endpoint of a bidirectional communication flow across a computer network. Be aware of the other common **netstat** options:

-l lists listening sockets.

-s displays statistics for each protocol.

-i displays a table of all network interfaces.

q_linux_host_sec_nmap_secp8

Which command should you use to scan for open TCP ports on your Linux system? (Tip: enter the command as if in Command Prompt.)

Answers:

nmap -sT

nmap -sT

Explanation:

Use **nmap -sT** to scan for open TCP ports. Open ports can provide information about which operating system a computer uses and might provide entry points or information about ways to formulate an attack.

Use **nmap -sU** to scan for open UDP ports.

q_linux_host_sec_open_secp8

You need to increase the security of your Linux system by finding and closing open ports.

Which of the following commands should you use to locate open ports?

Answers:

netstat

***nmap**

traceroute

nslookup

Explanation:

Use **nmap** to locate open ports. Open ports can provide information about which operating system a computer uses and might provide entry points or information about ways to formulate an attack. Use one of the following commands to scan for open ports:

nmap -sT scans for TCP ports.

nmap -sU scan for UDP ports.

The **netstat** command shows the status of listening and non-listening sockets. A socket is an endpoint of a bidirectional communication flow across a computer network.

The **nslookup** command is used for name resolution requests.

The **traceroute** command tests and displays connectivity between devices.

q_linux_host_sec_service_secp8

What does the **netstat -a** command show?

Answers:

All listening sockets

All connected hosts

***All listening and non-listening sockets**

All network users

Explanation:

The **netstat -a** command shows the status of all listening and non-listening sockets.

q_linux_host_sec_uefi_bios_secp8

As a security analyst at a large corporation, you have been tasked with implementing physical device port hardening techniques to reduce potential avenues of physical attack. You are considering several techniques to accomplish this task.

Which of the following would be the most effective method to prevent unauthorized data transfer, installation of malicious software, or direct access to a system?

Answers:

Disabling unnecessary physical ports such as USB, HDMI, or serial ports

Implementing port control software

***Leveraging settings in device firmware or UEFI/BIOS**

Disabling the automatic network connection feature

Explanation:

Leveraging settings in device firmware or UEFI/BIOS is the most effective method. It allows you to disable physical ports or require a password before a device can boot from a nonstandard source like a USB drive. This can prevent unauthorized data transfer, installation of malicious software, or direct access to a system.

Disabling unnecessary physical ports such as USB, HDMI, or serial ports: This is a good practice as it reduces the number of potential entry points for an attacker. However, it does not prevent an attacker from using the remaining enabled ports to launch an attack.

Implementing port control software: This can provide additional protection by only allowing authorized devices to connect via physical ports based on device identifiers. However, it does not prevent an attacker from spoofing the identifiers of an authorized device.

Disabling the automatic network connection feature: This can prevent a device from using potentially insecure or rogue networks. However, it does not prevent an attacker from physically connecting to the device and launching an attack.

q_linux_host_sec_yum_secp8

You want to make sure no unneeded software packages are running on your Linux server.

Select the command from the drop-down list that you can use to see all installed RPM packages.

Answers:

yum list installed

yum list packages

yum list rpm packages

yum list installed

yum list rpm installed

Explanation:

Unneeded software takes disk space and could introduce security flaws. To see all the RPM packages installed on your Linux server, run the following command:

yum list installed

After running this command, complete the following:

Research the function of any unrecognized RPM package to determine whether it is necessary.

Use **yum** or **rpm** to uninstall unneeded packages.

q_conf_iptables_drop_secp8

Which action would you use in a rule to disallow a connection silently?

Answers:

***Drop**

Accept

Forward

Reject

Explanation:

The Drop action is used to disallow a connection silently; the sending system receives no notice. The Reject action also disallows a connection but sends a TCP RST packet or an ICMP port unreachable packet back to the system that sent the original packet.

Accept would allow the packet.

Forward is a chain, not an action in iptables.

Reject rejects the connection but will send a response back.

q_conf_iptables_input_secp8

In which of the iptables default chains would you configure a rule to allow an external device to access the HTTPS port on the Linux server?

Answers:

Forward

Output

***Input**

Accept

Explanation:

The Input chain would be where you would place the rule as it is used for inbound connections.

The Output chain is for outbound connections.

The Forward chain sends connections through the Linux server to another device.

The Accept action can be used in a rule to allow a connection. However, it is not a chain.

q_conf_iptables_rst_secp8

Which type of packet would the sender receive if they sent a connection request to TCP port 25 on a server with the following command applied?

sudo iptables -A OUTPUT -p tcp --dport 25 -j REJECT

Answers:

ICMP Unreachable Port

ACK

SYN

***RST**

Explanation:

Because the packet is TCP and is blocked by the Reject action, the server would send a TCP RST packet back to the sender.

ICMP Unreachable Port is sent by iptables if a UDP packet is blocked by the Reject action.

A SYN packet would indicate that the server is proceeding with the connection, which would not happen with the Reject action. If it were allowed, the ACK would generally be sent with the SYN to acknowledge the initial connection while the SYN starts the next part of the TCP three-way handshake.

q_conf_iptables_smtp_secp8

You have configured the following rules. What is the effect?

sudo iptables -A INPUT -p tcp --dport 25 -m conntrack --ctstate NEW,ESTABLISHED -j ACCEPT
sudo iptables -A OUTPUT -p tcp --sport 25 -m conntrack --ctstate ESTABLISHED -j ACCEPT

Answers:

Block SSH traffic

Allow SSH traffic

***Allow SMTP traffic**

Block SMTP traffic

Explanation:

These rules would allow inbound and outbound Simple Mail Transfer Protocol (SMTP) connections on TCP port 25, the default port for SMTP.

These rules use the Accept action, so they would not block SMTP or Secure Shell (SSH).

SSH is on TCP port 22, so these rules would not affect SSH.

q_conf_iptables_sudo_secp8

Which command would you use to list all of the currently defined iptables rules?

Answers:

sudo iptables -F

sudo iptables -A INPUT -j DROP

sudo /sbin/iptables-save

***sudo iptables -L**

Explanation:

sudo iptables -L lists all of the currently defined rules.

sudo iptables -A INPUT -j DROP would drop all incoming traffic.

sudo /sbin/iptables-save saves changes to iptables on Ubuntu.

sudo iptables -F would flush all current rules from iptables.

8.4 Wireless Overview

As you study this section, answer the following questions:

Which device broadcasts information and data over radio waves?

What are the two modes of wireless network configuration?

Where is a Wireless LAN Controller (WLC) installed?

In this section, you will learn to:

Configure a wireless connection.

The key terms for this section include:

Term	Definition
Service set identifier (SSID)	A unique name that identifies a wireless network.
Wireless access point (WAP)	A wireless access point broadcasts information and data over radio waves.
Wireless interface	The interface in a device, such as a laptop or smart phone, that connects to the wireless access point.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	4.1 Given a scenario, apply common security techniques to computing resources. Wireless devices Installation considerations Site surveys Heat maps Wireless security settings Wi-Fi Protected Access 3 (WPA3) AAA/Remote Authentication Dial-In User Service (RADIUS)
TestOut Security Pro	2.2 Harden Network Devices

	2.2.2 Configure and Access a Wireless Network 2.2.4 Harden a Wireless Network

8.4.1 Wireless Networking Overview (Lesson Video)

Transcript:

Wireless networking is now commonplace in most network environments. In fact, a lot of networks use it as the primary connection method. Chances are you probably have a wireless network in your home. In fact, setting up a residential wireless network at home is pretty simple. Even setting up the SSID broadcast and encryption protocol on the access point is very straightforward.

In an enterprise environment, setting up a wireless network isn't as simple. This is because there are additional considerations that need to be taken into account in an enterprise environment. But before we discuss the impact of wireless devices in an enterprise network, let's highlight a couple of things with consumer-grade home routers.
You probably only have a single wireless access point at home. This device is actually three devices in one: a router, a switch, and a wireless access point.
The router connects your home local area network to the ISP's network. The switch allows you to connect several network devices together using an Ethernet cable, most likely unshielded twisted pair. The wireless access point allows for wireless connections to the local area network.
An enterprise wireless network is different from a home wireless network in at least three different ways. First, instead of having a single all-in-one device, equipment is typically separated into distinct components that perform a single function. For example, a router only performs routing operations, a switch only performs switching operations, and a wireless access point only acts as a bridge between the wireless and wired network.
Second, enterprises need to support many more devices and cover a much larger area than home networks. Some enterprises need to support thousands of clients and cover entire business complexes; for example, many universities have wireless connectivity on the entire campus.
And third, devices need to be able to move around the enterprise without any connection troubles. The transition between different access points needs to be seamless.
In an enterprise network, this is done by using multiple access points, which are scattered throughout the campus to provide adequate coverage. The access points will typically all connect to the same local area network through a switch. Now, each of these access points can only support a limited number of clients, so having multiple access points also allows each access point to share the client load. For example, if this switch has the maximum number of connections, new wireless devices that require network access will be connected to this access point, here, instead. This is possible because the range of the access points here overlap, which actually brings up another important point: overlapping signals can cause interference.
It's also possible for devices to constantly bounce between connecting to this AP and this AP, and so on. This could be really frustrating. In addition, if any of these configuration settings on either of these APs is different, then this can cause connection issues, and the more APs you add to a network, the more devices you need to manage.
As you can see, a wireless network can quickly become a management nightmare. Luckily, enterprise networks use a device called a wireless LAN controller (WLC) that manages all the access points in a network. The typical enterprise wireless controller will be in a networking closet and connected to a switch. The controller can then communicate with and manage each of these APs.
In addition to managing configuration settings, the controller can also manage client connections and manage AP loads. In essence, a wireless controller allows multiple APs to work together as a single system, instead of each working in isolation.
It's important to know that a wireless controller by itself doesn't actually produce any type of wireless signal--that's the job of the AP. The controller only manages the APs.
Another type of wireless device is known as a light-weight access point, or LWAP.
LWAPs are used in conjunction with a wireless controller. LWAPs contain very little embedded intelligence or technology. They are connected to the wired network via a network cable and are able to communicate directly with the WLC, which handles things like client connections, authentication, propagating configurations, et cetera.
Let's next look at the two ways a wireless network can be configured. The first one is ad hoc mode.

In ad hoc mode, also called peer-to-peer mode or wireless mesh mode, there is no WAP or WLC. Instead, two or more wireless devices connect directly with each other to send and receive information. The more devices that connect, the more individual connections that are made. And you can see where the term wireless mesh comes from when you see all these individual connections.
The second mode is called infrastructure mode. In infrastructure mode, a workstation communicates with a notebook by sending the signal to the WAP which transfers it to the notebook system. The infrastructure mode is more scalable than ad hoc mode. The infrastructure mode also makes it easy to connect the wireless network to a wired network. It is not easy to do that with an ad hoc implementation.
Once you establish the wireless connection between the network interface card and the WAP, the wireless network operates similar to traditional wired Ethernet networks.
Now, it's important to know that wireless networks use what's called an unbounded medium to communicate. That is, they send signals in all directions that can be picked up by any device in range they aren't bounded by insulated wires like wired networks. Because of this, wireless networks are inherently less secure than a bounded, wired network, so you need to take extra precautions when securing a wireless network.

8.4.2 Wireless Installation (Lesson Video)

Transcript:

When you set up a wireless network, you can't just put up a bunch of wireless access points and call it a day. There are different installation considerations you'll need to look at before installing your devices. The first step is to understand and define the usage needs of your wireless network. Once you know them, it's time to conduct a site survey. In this lesson, we're going to discuss the site survey process.

A site survey ensures that the wireless network will perform as desired. It examines the physical layout and barriers of the location, which lets you determine where to install the access points. Multiple site surveys will be completed during the installation process.
There are three different types of site surveys performed at different times in the installation process: passive surveys, active surveys, and predictive surveys. If a survey isn't conducted properly, your network won't perform, and that will cost a lot more time and money than performing surveys correctly.
To conduct a survey, you'll need to use a Wi-Fi analyzer. A dedicated Wi-Fi analyzer tool can provide an in-depth look at the wireless signals in the area being tested. There are also several Wi-Fi analyzers programs you can run from a laptop, tablet, or smartphone.
Before you perform a survey, you need a diagram or map of your location. It's important to make sure that the map is properly scaled and labeled so you can get a proper reading. Many analyzer tools allow you to import the map so you can overlay the survey results.
The initial survey is a passive survey. This survey is performed without the analyzer connecting to any specific wireless access point. It's just in a listen-only mode. Temporary WAPs are placed, and the surveyor walks around with the analyzer to measure signal strength and interference levels.
Once the passive survey has been completed, a heat map is generated. A heat map shows Wi-Fi signal strength. They usually show strong signals in green, medium levels in yellow, and weak spots in red.
You may need to perform multiple passive surveys to determine the best placement for your access points. You also need to make sure that the WAPs are installed in secure locations so people can't physically access them. Once you've figured out where to install the WAPs and installed them, you should conduct an active survey.
During an active survey, you'll first connect the Wi-Fi analyzer to the access points to measure the network strength and look for any weak spots. Then you'll walk through the entire location again to thoroughly test every inch. You can also generate heat maps again to visually represent problem areas.
You also need to check for channel overlapping. If neighboring access points are set to overlapping channels, you'll end up dealing with performance issues and network drops as devices move between the different WAPs.
The last type of site survey is a predictive survey. Predictive surveys use software programs to load the building blueprints and determines where to install the WAPs. This can be done remotely and doesn't require someone to walk through the location to test everything. A predictive survey isn't as precise as a passive or active survey, but it can cost less and take less time.

That's it for this lesson. In this lesson, we talked about the process of installing a wireless network. Before we can do anything, we need to know the usage needs of the network. Then you can perform passive, active, and predictive site surveys to determine how to install your WAPs.

8.4.3 Wireless Networking Facts

Wireless networking is commonplace, both in home and business environments.

This lesson covers the following topics:

- Wireless network hardware
- Wireless access point (WAP) placement
- Site surveys and heat maps
- Wi-Fi authentication methods
- Advanced authentication

Wireless Network Hardware

The following table describes hardware used in wireless networks:

Wireless Network Hardware	Description
Wireless access point (WAP)	A wireless access point broadcasts information and data over radio waves. A wireless access point functions as a wireless hub. The wireless access point may provide a connection to a physical wired network. The two classes of wireless access points are fat and thin. Fat access points have everything necessary to manage wireless clients and broadcast the network. Fat access points are standalone devices. Thin access points are basically a radio and antenna. Thin access points can broadcast the network, but require another system to manage clients and the network. Thin access points are referred to as controller-based devices. A WAP uses an service set identifier (SSID) that associates a name with a wireless network. This makes it easier for users to connect wirelessly.
Wireless interface	The wireless interface in a device, such as a laptop or smart phone, connects to the wireless access point.

Wireless bridge	A wireless bridge connects two wireless networks together. The bridge is typically created using a wired connection between the two access points. A bridge can be implemented wirelessly using a wireless distribution system (WDS).
Wireless LAN controller (WLC)	A Wireless LAN controller is used in a enterprise environment to manage multiple access points. The WLC is placed in the networking closet and connected to a switch. The controller is able to communicate with and manage the wireless access points. The WLC is also able to manage client connects and access point loads. This allows the WAPs to operate and work together as a single system instead of each device working in isolation.
Lightweight access point (LWAP)	Lightweight access points are used in conjunction with the wireless controller. LWAPs contain very little technology and rely on the WLC to handle everything including client connections, authentication, updating configurations, etc. LWAP forwards frames to the WLC to make the decision to either drop the packet or forward it. If the packet is to be forwarded, the WLC sends it to the applicable LWAP to which the destination device is connected and then that WLC sends the packet to the destination.

Wireless Access Point (WAP) Placement

Wireless network installation considerations refer to the factors that ensure good availability of authorized Wi-Fi access points. A network with patchy coverage is vulnerable to rogue and evil twin attacks.

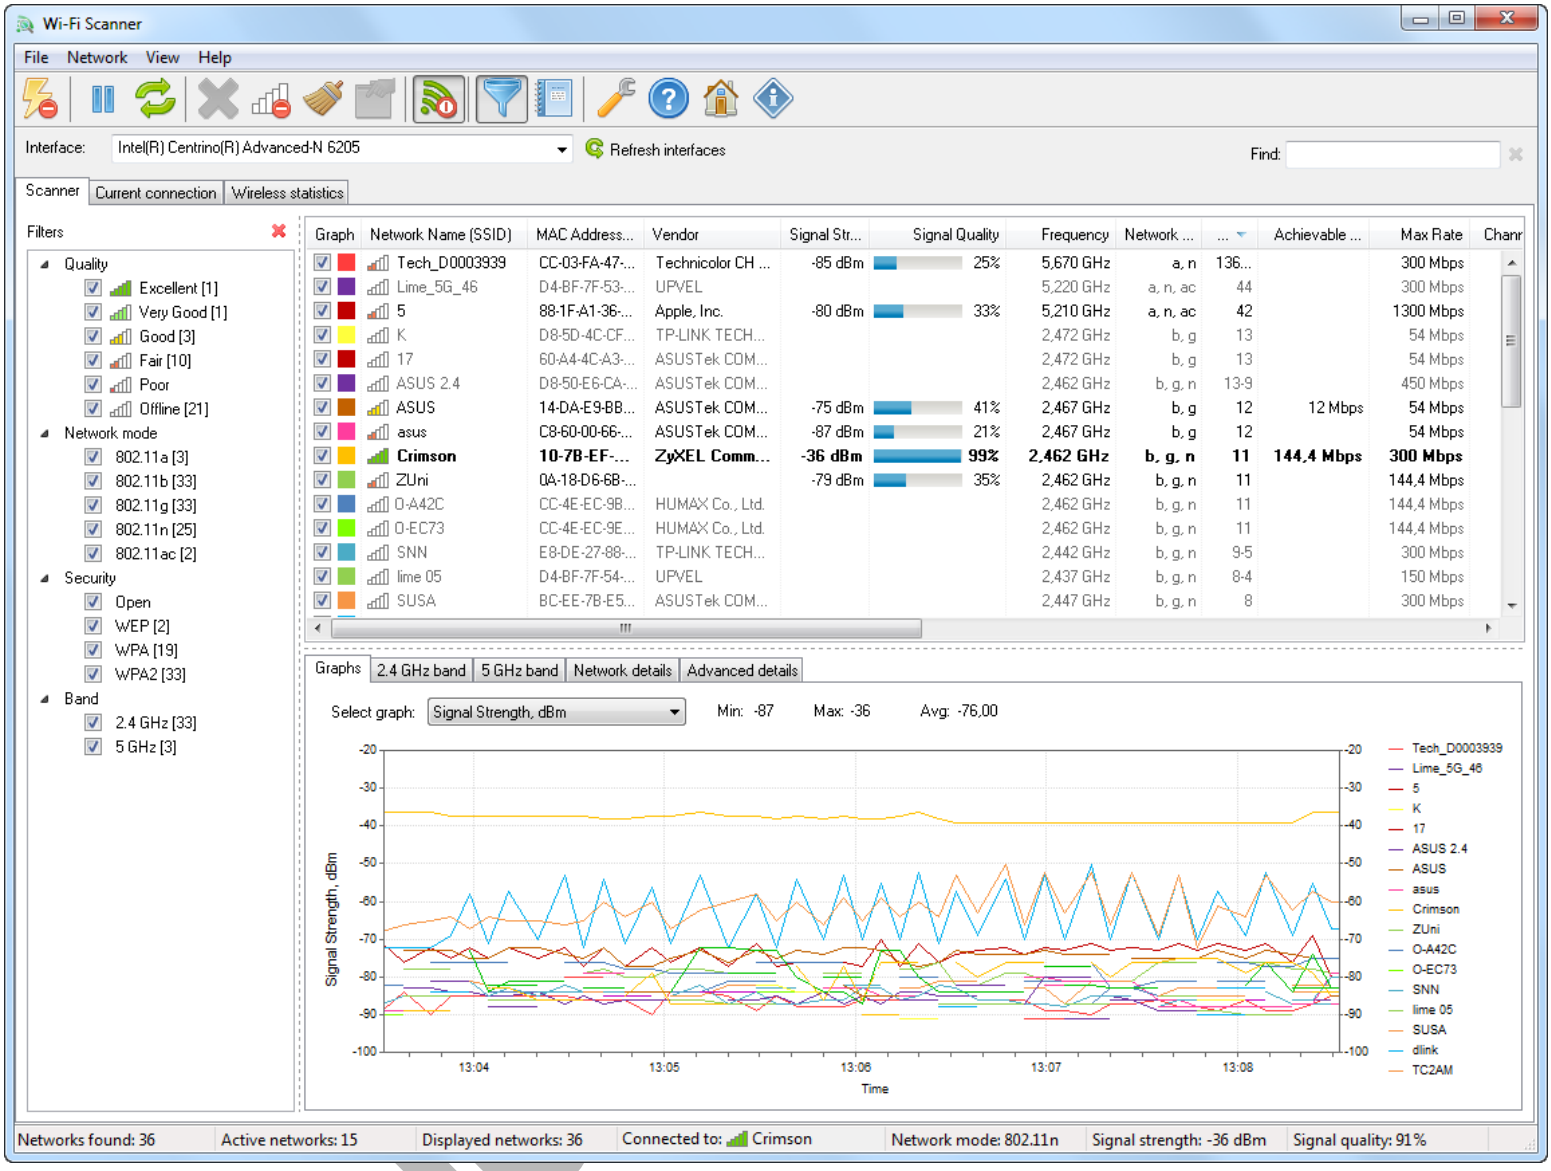
The 5 GHz band has more space to configure non-overlapping channels. Also note that a WAP can use bonded channels to improve bandwidth, but this increases risks from interference.

An infrastructure-based wireless network comprises one or more wireless access points, each connected to a wired network. The access points forward traffic to and from the wired switched network. Each WAP is identified by its MAC address, also referred to as its basic service set identifier (BSSID). Each wireless network is identified by its name or service set identifier (SSID) .

Wireless networks can operate in either the 2.4 GHz or 5 GHz radio band. Each radio band is divided into a number of channels, and each WAP must be configured to use a specific channel. For performance reasons, the channels chosen should be as widely spaced as possible to reduce interference.

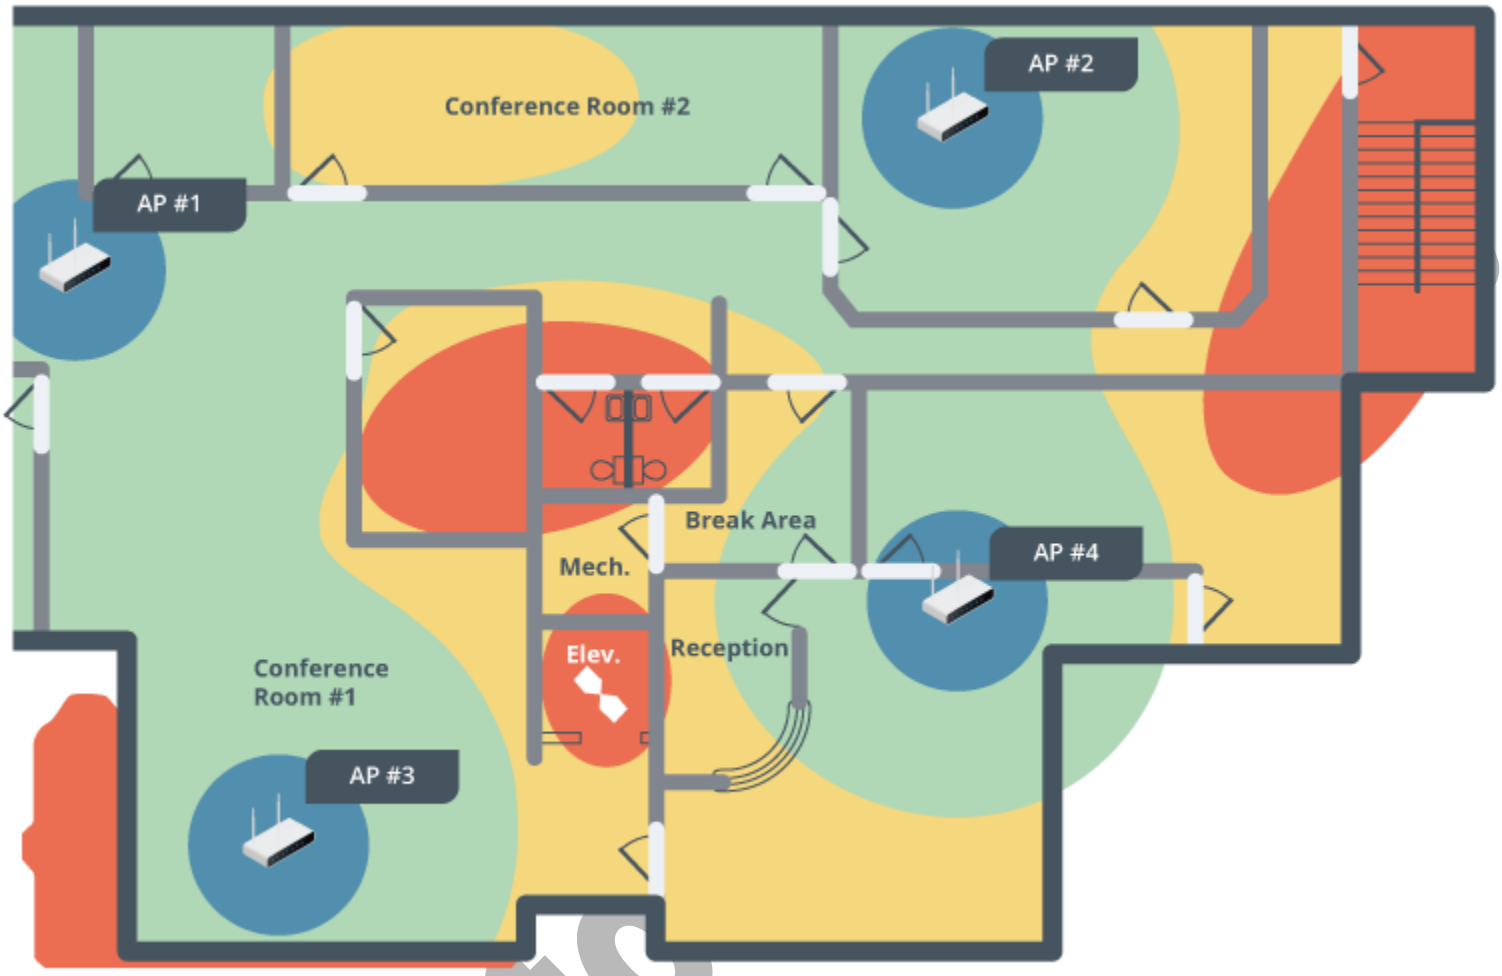
Site Surveys and Heat Maps

The coverage and interference factors mean that WAPs must be positioned and configured to cover the whole area with the least overlap as possible. A site survey is used to measure signal strength and channel usage throughout the area to cover. A site survey starts with an architectural map of the site, with features that can cause background interference marked. These features include solid walls, reflective surfaces, motors, microwave ovens, and so on. A Wi-Fi-enabled laptop or mobile device with Wi-Fi analyzer software installed performs the survey . The Wi-Fi analyzer records information about the signal obtained at regularly spaced points as the surveyor moves around the area.



Example output from Lizard System's Wi-Fi Scanner tool. (Screenshot courtesy of Lizard Systems.)

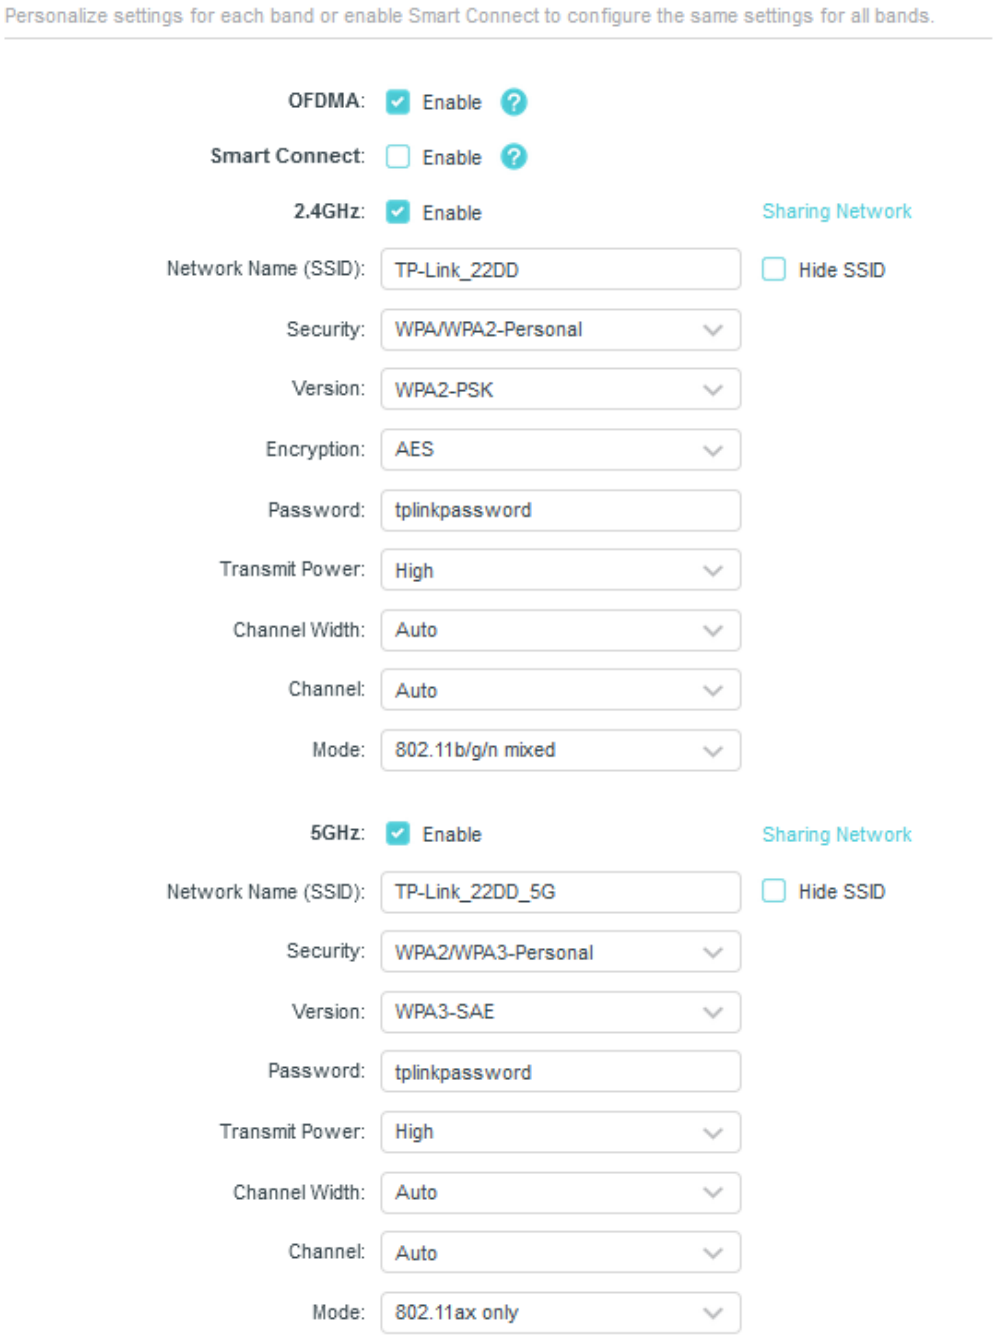
These readings are combined and analyzed to produce a heat map , showing where a signal is strong (green/blue) or weak (red), and which channel is being used and how they overlap. This data is then used to optimize the design by adjusting transmit power to reduce a WAP's range, changing the channel on a WAP, adding a new WAP, or physically moving a WAP to a new location.



An illustration of a heat map.

As well as the site design, a wireless network must be configured with security settings. Without encryption, anyone within range can intercept and read packets passing over the wireless network. Security choices are determined by device support for the various Wi-Fi security standards, by the type of authentication infrastructure, and by the purpose of the WLAN. Security standard determine which cryptographic protocols are supported, the means of generating the encryption key, and the available methods for authenticating wireless stations when they try to join (or associate with) the network.

The first version of Wi-Fi Protected Access (WPA) was designed to fix critical vulnerabilities in the earlier wired equivalent privacy (WEP) standard. Like WEP, version 1 of WPA uses the RC4 stream cipher but adds a mechanism called the Temporal Key Integrity Protocol (TKIP) to make it stronger.



Configuring a TP-LINK SOHO access point with wireless encryption and authentication settings. In this example, the 2.4 GHz band allows legacy connections with WPA2-Personal security, while the 5 GHz network is for 802.11ax (Wi-Fi 6) capable devices using WPA3-SAE authentication. (Screenshot used with permission from TP-Link Technologies.)

As setting up an access point securely is relatively complex for residential consumers, vendors have developed a system to automate the process called Wi-Fi Protected Setup (WPS) . To use WPS, both the access point and wireless station (client device) must be WPS-capable. Typically, the devices will have a push button. Activating this on the access point and the adapter simultaneously will associate the devices using a PIN, then associate the adapter with the access point using WPA2. The system generates a random SSID and PSK. If the devices do not support the push button method, the PIN (printed on the WAP) can be entered manually.

Unfortunately, WPS is vulnerable to a brute force attack. While the PIN is eight characters, one digit is a checksum and the rest are verified as two separate PINs of four and three characters. These separate PINs are many orders of magnitude simpler to brute force, typically requiring just hours to crack. On some models, disabling WPS through the admin interface does not actually disable the protocol, or there is no option to disable it. Some APs can lock out an intruder if a brute force attack is detected, but in some cases, the attack can just be resumed when the lockout period expires.

To counter this, the lockout period can be increased. However, this can leave APs vulnerable to a denial of service (DoS) attack. When provisioning a WAP, it is essential to verify what steps the manufacturer has taken to make their WPS implementation secure and to use the required device firmware level identified as secure.

The Easy Connect method, announced alongside WPA3, is intended to replace WPS as a method of securely configuring client devices with the information required to access a Wi-Fi network. Easy Connect is a brand name for the Device Provisioning Protocol (DPP).

Each participating device must be configured with a public/private key pair. Easy Connect uses quick response (QR) codes or near-field communication (NFC) tags to communicate each device's public key. A smartphone is registered as an Easy Connect configurator app and associated with the WAP using its QR code. Each client device can then be associated by scanning its QR code or NFC tag in the configurator app. As well as fixing the security problems associated with WPS, this is a straightforward means of configuring headless Internet of Things (IoT) devices with Wi-Fi connectivity.

Wi-Fi Authentication Methods

In order to secure a network, you must confirm that only valid users are connecting to it. Wi-Fi authentication comes in three types: personal, open, and enterprise. Within the personal category, there are two methods: pre-shared key authentication (PSK) and simultaneous authentication of equals (SAE).

WPA2 Pre-Shared Key Authentication

In WPA2, pre-shared key (PSK) authentication uses a passphrase to generate the key used to encrypt communications. It is also referred to as group authentication because a group of users shares the same secret. When the access point is set to WPA2-PSK mode, the administrator configures a passphrase of between 8 and 63 ASCII characters. This is converted to a 256-bit HMAC (expressed as a 64-character hex value) using the PBKDF2 key stretching algorithm. This HMAC is referred to as the pairwise master key (PMK). The same secret must be configured on the access point and on each node that joins the network. The PMK is used as part of WPA2's 4-way handshake to derive various session keys.

All types of Wi-Fi personal authentication have been shown to be vulnerable to attacks that allow dictionary or brute force attacks against the passphrase. At a minimum, the passphrase must be at least 14 characters long to try to mitigate risks from cracking.

Wi-Fi Protected Access 3 (WPA3)

Neither WEP nor the original WPA version is considered secure enough for continued use. WPA2 uses the Advanced Encryption Standard (AES) cipher with 128-bit keys, deployed within the Counter Mode with Cipher Block Chaining Message Authentication Code Protocol (CCMP). AES replaces RC4 and CCMP replaces TKIP. CCMP provides authenticated encryption, which is designed to make replay attacks harder.

Weaknesses found in WPA2 led to its intended replacement by WPA3. The main features of WPA3 are as follows:

- **Simultaneous Authentication of Equals (SAE)** - replaces the Pre-Shared Key (PSK) exchange protocol in WPA2, ensuring an attacker cannot intercept the Wi-Fi password even when capturing data from a successful login.

Enhanced Open - encrypts traffic between devices and the access point, even without a password, which increases privacy and security on open networks.

Updated Cryptographic Protocols - replaces AES CCMP with the AES Galois Counter Mode Protocol (GCMP) mode of operation. Enterprise authentication methods must use 192-bit AES, while personal authentication can use either 128-bit or 192-bit.

Wi-Fi Easy Connect - allows connecting devices by scanning a QR code, reducing the need for complicated configurations while maintaining secure connections.

Wi-Fi performance also depends on device support for the latest 802.11 standards. The most recent generation (802.11ax) is being marketed as Wi-Fi 6. The earlier standards are retroactively named Wi-Fi 5 (802.11ac) and Wi-Fi 4 (802.11n). The performance standards are developed in parallel with the WPA security specifications. Most Wi-Fi 6 devices and some Wi-Fi 5 and Wi-Fi 4 products should support WPA3 either natively or with a firmware/driver update.

While WPA3 still uses a passphrase to authenticate stations in personal mode, it changes the method this secret is uses to agree session keys. The scheme used is called a Password-Authenticated Key Exchange (PAKE). In WPA3, the Simultaneous Authentication of Equals (SAE) protocol replaces the 4-way handshake, which has been found vulnerable to various attacks. SAE uses the Dragonfly handshake, which is basically Diffie-Hellman over elliptic curves key agreement, combined with a hash value derived from the password and device MAC address to authenticate the nodes. With SAE, there should be no way for an attacker to sniff out the handshake to obtain the hash value and try to use an offline brute force or dictionary attack to recover the password. Dragonfly also implements ephemeral session keys providing forward secrecy.

The configuration interfaces for access points can use different labels for these methods. You might see WPA2-Personal and WPA3-SAE rather than WPA2-PSK and WPA3-Personal, for example. Additionally, an access point can be configured for WPA3 only or with support for legacy WPA2 (WPA3-Personal Transition mode). Researchers already found flaws in WPA3-Personal, one of which relies on a downgrade attack to use WPA2 (wi-fi.org/security-update-april-2019).

Advanced Authentication

Wireless enterprise authentication modes, such as WPA2/WPA3-Enterprise, include several essential components designed to improve security for corporate wireless networks. One important element is 802.1x authentication, which provides a port-based network access control framework, ensuring that only authenticated devices are granted network access. Typically, 802.1x requires an authentication server such as RADIUS (Remote Authentication Dial-In User Service), which verifies the credentials of users or devices trying to connect to the network.

In enterprise mode authentication schemes, users have a unique set of credentials rather than a shared passphrase as used in WPA2/WPA3 personal mode. Requiring each user or device to authenticate using unique credentials allows network administrators to track network usage at a granular level. The protocol also supports multiple Extensible Authentication Protocol (EAP) types, such as EAP-TLS, EAP-TTLS, or PEAP, which define specific authentication methods. EAP-TLS, for instance, uses client-server certificates for mutual authentication, while EAP-TTLS and PEAP utilize a server-side certificate. The server-side certificate is used to establish a secure tunnel for transmitting user credentials and helps devices validate the legitimacy of the access point. Enterprise mode authentication includes dynamic encryption key management, automatically changing the encryption keys used during a user's session.

Remote Authentication Dial-In User Service (RADIUS)

The Remote Authentication Dial-In User Service (RADIUS) standard is published as an Internet standard. There are several RADIUS server and client products.

The NAS device (RADIUS client) is configured with the IP address of the RADIUS server and with a shared secret. This allows the client to authenticate to the server. Remember that the client is the access device (switch, access point, or VPN gateway), not the user's PC or laptop. A generic RADIUS authentication workflow proceeds as follows:

The user's device (the supplicant) makes a connection to the NAS appliance, such as an access point, switch, or remote access server.

The NAS prompts the user for their authentication credentials. RADIUS supports PAP, CHAP, and EAP. Most implementations now use EAP, as PAP and CHAP are not secure. If EAP credentials are required, the NAS enables the supplicant to transmit EAP over LAN (EAPoL) data, but not any other type of network traffic.

The supplicant submits the credentials as EAPoL data. The RADIUS client uses this information to create an Access-Request RADIUS packet, encrypted using the shared secret. It sends the Access-Request to the AAA server using UDP on port 1812 (by default).

The AAA server decrypts the Access-Request using the shared secret. If the Access-Request cannot be decrypted (because the shared secret is not correctly configured, for instance), the server does not respond.

With EAP, there will be an exchange of Access-Challenge and Access-Request packets as the authentication method is set up and the credentials verified. The NAS acts as a pass-thru, taking RADIUS messages from the server, and encapsulating them as EAPoL to transmit to the supplicant.

At the end of this exchange, if the supplicant is authenticated, the AAA server responds with an Access-Accept packet; otherwise, an Access-Reject packet is returned.

Optionally, the NAS can use RADIUS for accounting (logging). Accounting uses port 1813. The accounting server can be different from the authentication server.

8.4.4 Configuring a Wireless Connection (Demo Video)

Transcript:

Connecting to Wi-Fi is something pretty much everyone does these days, but there are some additional settings that many users are not aware of. In this demonstration, we are going to go and see where you can configure these additional settings.

I have a PC that has a USB Wi-Fi adapter. When click on the taskbar you can see we are not connected to any networks. Our Wi-Fi adapter is on however its just not connected to anything. When we click this arrow, we are shown the available wireless networks around this area.
To connect to a wireless network, I find the SSID, which is right here. I can click it once and I'm able to click Connect. From here, I'm prompted for the passphrase. We have that set up to be LearningIsCool. I can then click here to verify that I typed it in correctly and click Next. Great were connected and ready to go.
Let's look at our wireless profiles. To see these, we need to go to **Start** >**Settings**>Once you successfully connect to a wireless, the computer creates what's called a profile.
The profile identifies wireless networks that have been connected to it in the past. These profiles are saved so you can connect to the same network again later.
Click on the profile to change its properties about the connection.
The first thing I can do is tell this to connect automatically to this wireless. If it's one that you want to use as your default, you might want to have this turned to On.
If you pay for bandwidth, you might want to tell this connection that you're on a metered connection. This will help prevent things such as Windows Update from downloading large files while connected. This is nice because you can then avoid charges for data you didn't plan on using. Let's click up here and go back.
You might want to add a wireless network profile manually. This might be if you're connecting to a wireless network and there is no SSID broadcast.

To do this, we select Add a new network. We can then enter our network name here. I'll put in Testout_Hidden and for Security type, I'll select WPA2-Personal from the list. I need to enter a security key which will be the same LearningIsCool. I then have the option to connect automatically and also to connect even if this network isn't broadcasting. I'll click Save here at the bottom, and we've added a network manually. Since were already connected to an existing network we will have to go back down to your Wi-Fi connected and click connect on the Testout_Hidden. Once doing so it will connect to this network now. Keep note you may only want to update what Wi-Fi networks you want to connect to automatically if there are many around the same location.
To remove a network you no longer want, you select the Wi-Fi connection that you want to remove and Right Click to select the Forget option. This doesn't show you a confirmation dialog, so pay attention and make sure you're removing the right one. This can also be done in the Manage known networks.
Mobile Hotspot is a feature that allows you to create a hotspot on your computer. Instead of you connecting to a hotspot you are making this computer the hotspot. An example could be having one computer plugged into a wired internet connection and then the same computer provided wireless to share the internet connection. Not only can it make a hotspot off a wired connection it can reshare a wireless connection too. In our task bar there is a quick option to turn on mobile hotspot. After clicking on it our mobile hotspot will be active. In order to see more settings for this we must go to or Network& internet settings. Were already in our settings so we will take a look at it from here. The setting were looking for is Mobile hotspot. The settings here provide key information such as the password for this Mobile hotspot. If we select edit were able to change the Network name and password if need be. If you're on your battery this setting here for Power saving will be helpful because it will automatically shut Mobile hotspot off once it notices no devices are connecting to it. The last thing I would like to point out is this hotspot is only limited to 8 devices so if you have more devices then that then this setup will not work for you.
A lot of the available features for a wireless adapter are still available however it may be hidden for the public eye. A regular user may not be concerned about them, but we are. Open the search and type cmd. This will bring up the option to open the command prompt. In our command prompt let's type in "netsh wlan show wirelesscapabilities". Press enter. This list will show us what is supported by the wireless adapter and what is not. For example, ANQP Service Information Discovery was the previous option listed in windows 10 for hotspot 2.0. its not listed in our settings on this Windows install however its still supported by the wireless adapter.
That's it for this demo. In this demo, we looked at how to connect to a wireless network in Windows. We then looked at Mobile hotspot and supported capabilities of a wireless adapter.

8.4.5 Configure a Wireless Network (Simulation)

Scenario

You are a network technician for a small corporate network. You just installed a Ruckus zone controller and wireless access points throughout your office buildings using wired connections. You now need to configure basic wireless network settings.

Access the Wireless Controller console through Chrome on **http://192.168.0.6** with the username **admin** and the password **password** . The username and password are case-sensitive.

In this lab, your task is to:

Create a WLAN using the following settings:

Name: **CorpNet Wireless**

ESSID: **CorpNet**

Type: **Standard Usage**

Authentication: **Open**

Encryption: **WPA2**

Encryption algorithm: **AES**

Passphrase: **@CorpNetWeRSecure!**

Connect the Exec-Laptop in the Executive office to the new wireless network.

Explanation

Complete this lab as follows:

Access the Ruckus zone controller.

From the taskbar, select **Google Chrome** .

In the URL field, enter **192.168.0.6** and press **Enter** .

Maximize the window for better viewing.

Log into the Wireless Controller console.

In the Admin field, enter **admin** (case-sensitive).

In the Password field, enter **password** as the password.

Select **Login** .

Create a new WLAN.

Select the **Configure** tab.

From the left menu, select **WLANs** .

From the right, under WLANs, select **Create New** .

In the New Name field, enter **CorpNet Wireless** .

In the ESSID field, enter **CorpNet** .

Under Type, make sure **Standard Usage** is selected.

Under Authentication Options, make sure **Open** is selected.

Under Encryption Options, select **WPA2** .

For Algorithm, make sure **AES** is selected.

In the Passphrase field, enter **@CorpNetWeRSecure!** .

Select **OK** .

Switch to the Exec-Laptop.

From the top left, select **Floor 1** .

Under Executive Office, select **Exec-Laptop** .

Connect to the new CorpNet wireless network.

In the notification area, select the ***wireless network*** icon to view the available networks.

Select **CorpNet** .

Select **Connect** .

Enter **@CorpNetWeRSecure!** for the security key.

Select **Next** .

Select **Yes** to make the computer discoverable on the network. The CorpNet network now shows as being connected and secured.

8.4.6 Practice Questions (Section Quiz)

q_wireless_access_point_secp8

Which of the following is used on a wireless network to identify the network name?

Answers:

***SSID**

MAC address

IP address

Subnet mask

Explanation:

Wireless devices use the service set identifier (SSID) to identify a network name. All devices on a wireless network use the same SSID.

The MAC address is a unique physical device address.

The IP address is a logical address that includes both the logical network and the logical device address.

The subnet mask is used with the IP address to identify the network portion of the IP address.

q_wireless_heat_map_secp8

Which of the following is generated after a site survey and shows the Wi-Fi signal strength throughout the building?

Answers:

***Heat map**

Diagram

Analyzer

Ad hoc

Explanation:

A heat map is generated following a site survey. A heat map shows the Wi-Fi signal strength in different locations.

A diagram of the location is needed so survey results can be overlaid.

A Wi-Fi analyzer is used to perform a site survey.

Ad hoc wireless configuration mode provides wireless communication without a wireless access point. This is not a type of site survey.

q_wireless_pake_secp8

You are a network security consultant for a small business that is setting up a new wireless network. The business owner is concerned about the security of the network, especially in terms of protecting against unauthorized access.

The owner is not technically savvy and wants a solution that is secure but also user-friendly.

Which of the following authentication methods would you recommend?

Answers:

Pre-shared key (PSK)

Extensible Authentication Protocol (EAP)

***Password-Authenticated Key Exchange (PAKE)**

Open System Authentication

Explanation:

Password-Authenticated Key Exchange (PAKE) is the correct answer. It is a method that allows users to establish a secure communication channel by using a password. It provides a good balance between security and user-friendliness. Even if an attacker intercepts the password, they cannot use it to derive the encryption key. This makes PAKE a good choice for a small business owner who wants a secure but user-friendly authentication method.

While PSK is relatively user-friendly, it is not the most secure option. If the pre-shared key is compromised, the entire network is at risk. Furthermore, managing PSKs can become complex as the number of users increases.

Extensible Authentication Protocol (EAP) is a secure authentication framework that supports multiple authentication methods. However, it can be complex to set up and manage, especially for a small business owner who is not technically savvy.

Open System Authentication offers no real authentication or security. It simply allows any device to connect to the network as long as it knows the network's SSID. This would not be a suitable choice for a business owner who is concerned about network security.

q_wireless_placement_secp8

The IT manager has tasked you with installing the new Wireless LAN controller (WLC).

Where should you install the controller?

Answers:

Lobby

***Network closet**

Manager's office

Roof

Explanation:

A WLC should be placed in the networking closet and connected to a switch so it can communicate with and manage the wireless access points.

None of the other locations are valid locations to install the WLC.

q_wireless_radius_auth_secp8

You are a network administrator for a large organization that uses RADIUS for network authentication. One day, you receive a report that a user is unable to access the network.

You check the RADIUS server logs and see that the user's authentication request was received, but no Access-Accept or Access-Reject message was sent back to the user.

Which of the following could be the MOST likely cause of this issue?

Answers:

The user entered the wrong password.

***The RADIUS server is down.**

The user is not in the RADIUS server's database.

The network connection between the user and the RADIUS server is unstable.

Explanation:

The RADIUS server is down is the correct answer. If the RADIUS server is down, it will not be able to send any messages back to the user. This would explain why no Access-Accept or Access-Reject message was sent back to the user.

If the user entered the wrong password, the RADIUS server would still send an Access-Reject message back to the user. Therefore, this is not the most likely cause of the issue.

If the user is not in the RADIUS server's database, the server will still send an Access-Reject message back to the user. Therefore, this is not the most likely cause of the issue.

If the network connection was unstable, the RADIUS server might not have received the user's authentication request in the first place. However, the logs show that the server did receive the request. Therefore, this is not the most likely cause of the issue.

q_wireless_security_01_secp8

Which type of wireless access point is generally used in a residential setting?

Answers:

LWAP

***SOHO**

Bridge

WLC

Explanation:

In a small office or residential location, a Small Office Home Office (SOHO) wireless router is often used. These devices are three different devices in one:

A router function connects the internal LAN to the internet.

A switch portion connects the internal wired LAN devices.

An access point portion allows the internal wireless devices to connect to the network.

Lightweight access points (LWAPs) are used in conjunction with a wireless controller.

A wireless bridge connects two wireless networks.

A Wireless LAN controller (WLC) is used in an enterprise environment to manage multiple access points.

q_wireless_security_02_secp8

You need to implement a solution to manage multiple access points in your organization.

Which of the following would you MOST likely use?

Answers:

LWAP

SOHO

Bridge

***WLC**

Explanation:

A Wireless LAN controller (WLC) is used in an enterprise environment to manage multiple access points. A WLC is placed in the networking closet and connected to a switch. The controller is able to communicate with and manage the wireless access points.

In a small office or residential location, a Small Office Home Office (SOHO) wireless router is often used.

Lightweight access points (LWAPs) are used in conjunction with a wireless controller.

A wireless bridge connects two wireless networks.

q_wireless_site_survey_01_secp8

Which of the following devices would you use to perform a site survey?

Answers:

Heat map

Wireless access point

***Wi-Fi analyzer**

Wireless interface

Explanation:

A Wi-Fi analyzer is used to perform a site survey. A Wi-Fi analyzer can be a specialized tool or a software program running on a laptop, smartphone, or tablet.

A heat map is generated following a site survey. A heat map shows the Wi-Fi signal strength in different locations.

A wireless access point (WAP) broadcasts information and data over radio waves. WAPs function as wireless hubs.

A wireless interface in a device, such as a laptop or smartphone, connects to a wireless access point.

q_wireless_site_survey_02_secp8

Which of the following types of site surveys should be performed first?

Answers:

Active

***Passive**

Predictive

Ad hoc

Explanation:

An initial site survey performed should be a passive survey. This survey is performed without the analyzer connecting to any specific WAP and is in a listen-only mode.

An active survey is performed after multiple passive surveys have been completed and the wireless access points have been placed. An active survey verifies proper coverage has been achieved.

A predictive survey uses software programs to load the building blueprints and determine where to install the WAPs.

An ad hoc wireless configuration mode provides wireless communication without a wireless access point. Ad hoc mode is not a type of site survey.

q_wireless_wap_01_secp8

Which of the following is responsible for broadcasting information and data over radio waves?

Answers:

***Wireless access point**

Wireless bridge

Wireless interface

Wireless LAN controller

Explanation:

A wireless access point (WAP) broadcasts information and data over radio waves. WAPs function as wireless hubs.

A wireless bridge connects two wireless networks.

A wireless interface in a device, such as a laptop or smartphone, connects to a wireless access point.

A Wireless LAN controller is used in an enterprise environment to manage multiple access points.

q_wireless_wap_02_secp8

Which class of wireless access point (WAP) has everything necessary to manage clients and broadcast a network already built into its functionality?

Answers:

Thin

Bridge

Ad hoc

***Fat**

Explanation:

Fat access points have everything necessary to manage wireless clients and broadcast a network. Fat access points are standalone devices.

Thin access points are basically a radio and antenna. Thin access points can broadcast a network but require another system to manage clients and the network.

A wireless bridge connects two wireless networks.

Ad hoc wireless configuration mode provides wireless communication without a wireless access point.

q_wireless_wap_03_secp8

The network administrator of an educational institution is upgrading an existing wireless network. The campus has various buildings, each having multiple floors, and the aim is to ensure consistent Wi-Fi coverage across the entire campus.

To achieve this, a site survey and heat map creation will guide the placement and configuration of wireless access points (WAPs).

Which of the following would MOST accurately represent the correct actions based on the survey results?

Answers:

Place WAPs in areas indicated as red in the heat map and increase transmit power to the maximum in all devices.

***Place WAPs in areas with weak signals (green/blue in the heat map) and carefully manage transmit power to avoid unnecessary overlap.**

Ignore the heat map and place WAPs in every room regardless of signal strength to ensure maximum coverage.

Set all WAPs to use the same channel to ensure a seamless transition for users moving between different WAP coverage areas.

Explanation:

WAPs belong in areas where the signal is weak to ensure consistent coverage. Managing the transmit power helps to fine-tune the coverage area, reducing unnecessary overlap and interference.

Placing WAPs in areas already marked red (strong signal) on the heat map would lead to unnecessary overlap, causing interference.

This approach could lead to too much overlap and interference between WAPs, resulting in poor performance. It also ignores the valuable information the heat map provides.

Setting all WAPs to the same channel can cause co-channel interference. Instead, WAPs should use different, non-overlapping channels to avoid interference. The channel selection should follow the site survey results to optimize the network performance.

q_wireless_wap_04_secp8

The IT department of a medium-sized company is preparing to implement a new wireless network to enhance mobility and productivity within the workplace.

The IT team has conducted an in-depth analysis of the office layout and user requirements and now faces the task of strategically positioning the wireless access points (WAPs) throughout the office. The team understands the potential risks and challenges involved in wireless deployments.

Which considerations should the IT team take into account when strategically positioning the wireless access points (WAPs) in the company's new wireless network? (Select two.)

Answers:

***Optimal coverage of the office area to ensure reliable connectivity for all users.**

***Minimizing interference from nearby electronic devices to enhance network performance.**

Positioning WAPs based on the design preferences of the company's management.

Ensuring the WAPs are accessible only to employees with specific job roles and responsibilities.

Making sure the service set identifier (SSID) that associates a name with a wireless network is disabled.

Explanation:

The following are considerations that the IT team should take into account:

Strategically positioning the wireless access points (WAPs) to achieve optimal coverage is essential to ensure reliable connectivity for all users throughout the office and eliminate potential dead zones in every corner of the workplace.

Minimizing interference from nearby electronic devices is crucial for enhancing network performance and reducing connectivity issues. To mitigate this, the IT team should identify potential sources of interference and strategically place the WAPs away from these devices.

Network performance and coverage should take precedence over design preferences to ensure optimal connectivity and productivity.

Access control measures determine who can connect to the wireless network and what level of privileges they have. While important for network security, this consideration is distinct from the physical placement of WAPs.

A WAP uses a service set identifier (SSID) that associates a name with a wireless network. This makes it easier for users to connect wirelessly. Disabling the SSID would disable the WAP service.

q_wireless_wpa3_upgrade_secp8

You are a network administrator for a large corporation that handles sensitive data. The corporation is currently using WPA2 for Wi-Fi authentication.

However, there have been recent concerns about the security of the network. You have been tasked with deciding whether to upgrade the Wi-Fi authentication method.

Which of the following would be the BEST choice?

Answers:

Continue using WPA2.

Switch to WEP.

Switch to WPA.

***Upgrade to WPA3.**

Explanation:

Upgrade to WPA3 is the correct answer. WPA3 is the latest and most secure Wi-Fi authentication method currently available. It includes several improvements over WPA2, such as stronger encryption and more secure password-based authentication. Therefore, upgrading to WPA3 would be the best choice for a corporation handling sensitive data.

While WPA2 is more secure than its predecessor, WPA, it has known vulnerabilities that can be exploited by determined attackers. Therefore, continuing to use WPA2 would not be the best choice for a corporation handling sensitive data.

WEP is an older encryption standard and is considered to be the least secure. It has numerous well-known vulnerabilities and would not be a suitable choice for a corporation handling sensitive data.

WPA is more secure than WEP but less secure than WPA2 and WPA3. It was only intended as an interim solution during the development of WPA2. Therefore, switching to WPA would not be the best choice.

8.5 Wireless Attacks

As you study this section, answer the following questions:

What is the difference between bluejacking and bluesnarfing?

What is an initialization vector used for?

How can you discover rogue access points?

What is the difference between passive and active radio frequency identification (RFID) tags?

In this section, you will learn to:

Detect rogue hosts.

Configure rogue host protection.

The key terms for this section include:

Term	Definition
Rogue access points	Any unauthorized access point added to a network.

Initialization vector (IV)	A seed value used in encryption. The seed value and the key are used in an encryption algorithm to generate additional keys or encrypt data.
Radio frequency identification (RFID)	RFID uses radio waves to transmit data from small circuit boards called RFID tags to special scanners.
Near Field Communication (NFC)	NFC allows two-way communication between two devices. The devices must be within a few centimeters of each other. NFC is a newer technology built on RFID.
Interference	A signal that corrupts or destroys a wireless signal. Interference can affect communication of access points and other wireless devices.
Evil twin	A wireless access point that deceives users into believing that it is a legitimate network access point.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.2 Explain common threat vectors and attack surfaces. Unsecure networks Wireless Bluetooth 2.4 Given a scenario, analyze indicators of malicious activity. Physical attacks Radio frequency identification (RFID) cloning Network attacks Wireless Credential replay 4.1 Given a scenario, apply common security techniques to computing resources Wireless devices

	Installation considerations Wireless security settings Wi-Fi Protected Access 3 (WPA3) Authentication protocols
TestOut Security Pro	2.2 Harden network devices 2.2.2 Configure and access a wireless network 2.2.4 Harden a wireless network

8.5.1 Wireless Attacks (Lesson Video)

Transcript:

Because wireless networks use an unbounded communication method, they're especially vulnerable to attacks. This includes all types of wireless networks, as in Wi-Fi, Bluetooth, RFID, and even NFC. In this lesson, I'm going to go over the various attacks that threaten wireless networks.

Because network security is a top priority, it's common for network administrators to implement stringent rules and limit website access. Some users find this very frustrating.
To try to evade these rules, users sometimes install an access point on their own computer. This is known as a soft access point. A network hacker who has gained access to a network, perhaps using MAC spoofing, might do the same. This is called a rogue access point or an unauthorized association.
Here's the big problemâ€”most employees don't understand the importance of securing their soft access point or even how to do it. So they just leave it open to hackers. When an attacker discovers an access point, they're able to run various types of vulnerability scanners from outside the company, perhaps from a car or adjacent building or even from several miles away. Keep in mind that if a hacker can gain some type of physical access to your company, they can also hide a physical rogue access point as well. This is often done by configuring an extremely compact and powerful hardware device called a Raspberry Pi as their access point.
A rogue access point that's placed on the network by a malicious attacker can be used to run what's called an evil twin attack. Here's how this worksâ€”say your organization currently has a wireless network with a SSID of MyCompanyWiFi. The attacker configures their own access point with the same SSID and places it near the organization's building. Then the attacker uses a jamming or disassociation attack to knock users off the legitimate network. When users reconnect to the network, they're now connecting to the attacker's access point instead.
Once a victim is connected to a rogue access point, the attacker can capture all data flowing through it. The user shouldn't notice anything different since their internet is still running like normal. These attacks are extremely dangerous as the attacker gains immediate access to all sorts of sensitive information.
To defend against these attacks, you should perform regular site surveys to locate any rogue access points. Your wireless networks encrypt data, which helps protect against sniffing. But some older standards, like WEP, are vulnerable due to improperly configured initialization vectors, or IVs.
When we encrypt data, we use a secret key that only we know. If we use the same key for everything we encrypt, it won't take long for the key to be compromised. This is where initialization vectors can help out. The IV is a random string that's added to the key to create a different key for each encryption process. Unfortunately, if we don't configure the IV properly, it can open us up to attacks.
Wired Equivalent Privacy, or WEP, was one of the first wireless security protocols that used IVs to help with encryption. The problem, though, was the IV was only 24 bits long and the key was 40 bits. This meant there was only approximately 16 million different IVs that could be generated. This may sound like a lot, but it actually meant that an IV would be repeated at least once every 4096 packets. It doesn't take much time to get 4096 packets, and attackers were able to develop programs that would flood the network with packets to find matching IVs. Once an attacker gets multiple IVs, they can begin decrypting the encryption key. After that, all communication is open and no longer secure.

No networks should use WEP anymore. Newer wireless standards such as WPA-2 don't even use IVs for encryption. For many of these wireless attacks to work, the attacker needs to kick everyone off the legitimate network and prevent them from reconnecting. They attempt this with jamming attacks or disassociation attacks.

A Wi-Fi jamming attack requires a special device that works by analyzing the spectrum used by wireless networks and then transmitting a powerful signal on the same frequencies. Basically, the jammer tries to be the loudest voice in the room so nearby devices can't see the legitimate wireless network. The hope is that they disconnect and are unable to reconnect again. Jamming devices are illegal and difficult to come by, though.

A disassociation attack, on the other hand, can be performed with a laptop. This is also know as a deauthentication attack. When a device connects to a wireless network, special unencrypted management packets are sent back and forth. A deauthentication attack takes advantage of this unencrypted process by sending fake, malicious deauthentication packets to kick people off the network. The attacker can select individual users or kick everyone off at once. Jamming and deauthentication attacks have the same end result, but they use very different methods.

Wi-Fi is used everywhere today and attackers are always working on methods to exploit weaknesses. Yet another wireless technology that can be susceptible to attacks is Bluetooth.

From headphones and speakers to watches, fitness devices, automobiles, and even refrigerators, Bluetooth devices are heavily integrated into our daily lives. This makes these devices attractive to malicious attackers. An attacker can gather all sorts of personal data and even take over our devices' embedded cameras and microphones.

One common Bluetooth attack is Bluejacking. When performing a Bluejacking attack, he or she looks for another Bluetooth device that's discoverable and sends unwanted messages to it. Attackers can't gain control of a device or steal any data so Bluejacking is more annoying than harmful.

Bluesnarfing, on the other hand, can be harmful. Bluesnarfing is when an attacker exploits a vulnerability in the OBject EXchange Protocol, or OBEX Protocol, to pair to a target device. Once paired, he or she is able to access all the victim's device data and then disconnect without leaving a trace.

The best defense against both of these attacks is to only enable Bluetooth when you need to and to not leave devices in Discovery Mode.

Radio frequency identification, or RFID, uses radio waves to transmit data from small circuit boards called RFID tags to special scanners. Active RFID tags, like those seen in a car's toll pass, have on-board batteries and can send signals over a long distance. Passive RFID tags, which are used in ID badges and credit cards, aren't powered. These tags instead rely on the RFID scanner's transferred energy.

A malicious attacker can build their own scanner to target these RFID tags. If an attacker can get close enough, they can scan the RFID chip and clone it. An attacker might also eavesdrop on the communication between the chip and reader and steal the data that way.

To protect against these attacks, RFID chips often operate at different frequencies, making it more difficult for an attacker to quickly complete a scan. Also, because most of these chips are passive, an attacker has to get extremely close for it to work. Near field communication, or NFC, is a newer technology that's built on RFID. NFC allows two-way communication between two devices. But they must be within a few centimeters of each other.

NFC is what allows us to use our smartphones to pay for items at the store. We can also use NFC to transfer files between two phones if they're right next to each other. NFC is vulnerable to the same types of attacks as RFID, but it requires the attacker to be incredibly close.

That'll wrap up this lesson. In this lesson, we looked at some different wireless communications attacks. We first looked at Wi-Fi and rogue access points, evil twin attacks, how an IV can be exploited, and also how jamming and disassociation attacks work. Then we looked at Bluetooth attacks, including Bluejacking and Bluesnarfing. Finally, we covered how RFID and NFC work and the security concerns associated with both of these devices.

8.5.2 Wireless Attack Facts

This lesson covers the following topics:

- Wireless attacks
- Rogue access points
- RFID/NFC attacks

Wireless Attacks

Wireless networks present particular security challenges and are frequently the vector for various types of attacks. Many organizations have set up and configured wireless networks, and if not configured properly, these networks can be susceptible to attack.

The following table explains common wireless attacks:

Wi-Fi Attack	Description
Wireless denial-of-service	A wireless denial-of-service (DoS) attack is usually designed to prevent clients from connecting to the legitimate access point. A wireless network can be disrupted by interference from other radio sources. These are often unintentional, but it is also possible for an attacker to purposefully jam the legitimate network by setting up a rogue access point with a stronger signal. Wireless DoS can also target clients. In the normal course of operations, an access point and client use management frames to control connections. A disassociation attack exploits the lack of encryption in management frame traffic to send spoofed frames. One type of disassociation attack injects management frames that spoof the MAC address of a single victim station in a disassociation notification, causing it to be disconnected from the network. Another variant of the attack broadcasts spoofed frames to disconnect all stations. As well as trying to redirect connections to an evil twin, a disassociation attack might also be used in conjunction with a replay attack aimed at recovering the network key.
Wireless replay and key recovery	Wireless authentication is vulnerable to various types of replay attacks that aim to capture the hashes used when a wireless station associates with an access point. Once the hash is captured, it can be subjected to offline brute force and dictionary cracking. A KRACK attack uses a replay mechanism that targets the WPA and WPA2 4-way handshake. KRACK is effective regardless of whether the authentication mechanism is personal or enterprise. It is important to ensure both clients and access points are fully patched against such attacks.
Evil twin attack	Rogue APs placed by an attacker can be used to run an evil twin attack. In this attack: The rogue AP is configured to mimic the legitimate network. The attacker uses a jamming or disassociation attack to knock users off the legitimate network. When users reconnect to the network, they connect to the attacker's AP. The attacker can monitor and capture all data that moves through the rogue AP. To protect against this attack, conduct a radio frequency (RF) noise analysis to detect a malicious rogue AP that uses jamming to force wireless clients to connect to it instead of legitimate APs.

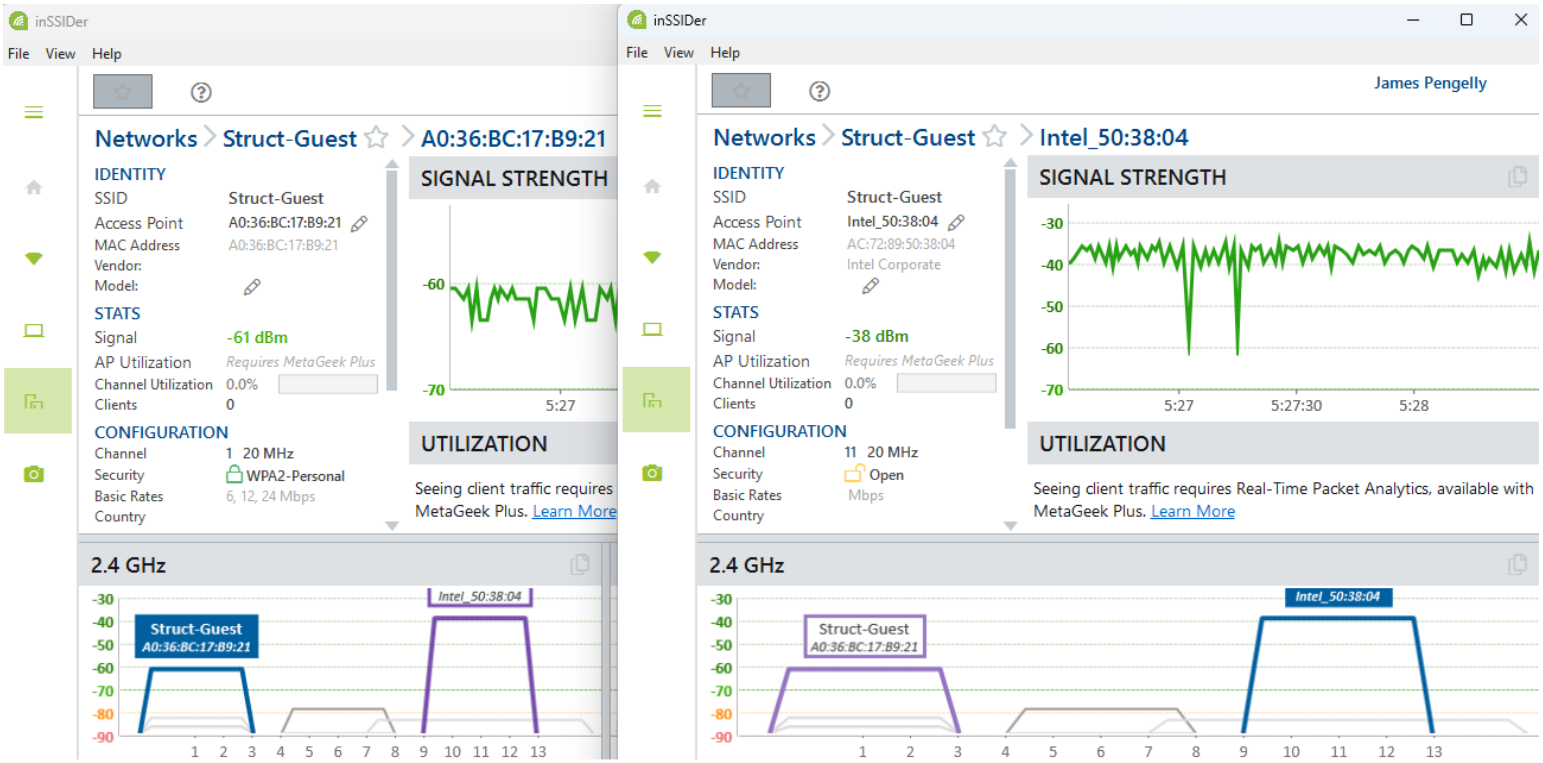
Initialization vector (IV) attack	An initialization vector is a seed value used in encryption. The seed value and the key are used in an encryption algorithm to generate additional keys or to encrypt data. Wired Equivalent Privacy (WEP) encryption reuses initialization vectors. The reuse of IVs makes it easy for attackers to crack them. This is known as an IV attack. Be aware that: The WEP IV is 24-bits, and the key is 40-bits. This allows for approximately 16 million IVs. An IV is repeated at least once every 4096 packets. Hackers developed programs that flood the network with packets, allowing them to find matching IVs quickly. Once enough IVs are obtained, the attacker can decrypt the encryption key. WEP encryption can be cracked in as little as 1-2 minutes. Due to the vulnerabilities of WEP, you should no longer use it. Newer standards, such as WPA2 and WPA3, do not use IVs in the encryption process.
Jamming attack	With wireless networks, interference is a signal that corrupts or destroys the wireless signal sent by APs and other wireless devices. Non-malicious interference includes the following: Electromagnetic interference (EMI) is interference caused by motors, heavy machinery, and fluorescent lights. Radiofrequency interference (RFI) is interference on the radio channel. It is caused by nearby wireless devices using the same channel, cordless phones, or microwave ovens. Adjacent channels on wireless APs have a small degree of overlap. To avoid interference with other wireless APs within the same vicinity, use channels that don't overlap neighboring wireless APs. Some interference is malicious in nature and designed to disrupt wireless network communications. Malicious interference is sometimes referred to as jamming. In a jamming attack, a transmitter is tuned to the same frequency and the same type of modulation as the wireless network. The jamming signal overrides the legitimate wireless network radio signals at the receiving devices. The following list describes different types of jamming signals that can be used to disrupt a Wi-Fi network. *Spark jamming* is the most effective type of Wi-Fi interference attack. It repeatedly blasts receiving equipment with high-intensity, short-duration RF (radio frequency) bursts at a rapid pace. Experienced

	RF signal technicians can usually identify this type of attack quickly because of the regular nature of the signal. *Random noise jamming* produces radio signals using random amplitudes and frequencies. While not as effective as a spark attack, the random noise attack is harder to identify due to the intermittent and random nature of the interference. In fact, this type of signal is frequently mistaken for background radio noise that occurs naturally. *Random pulse jamming* uses radio signal pulses of random amplitude and frequency to interfere with a Wi-Fi network.
Disassociation/deauthentication attack	Wireless devices are vulnerable to deauthentication (deauth) and disassociation attacks because the 802.11 standard allows devices to be authenticated with multiple APs at once. When a device connects to a wireless network, special unencrypted management packets are sent back and forth. Deauthentication and disassociation attacks take advantage of these packets to disconnect devices from a network. Be aware that: To execute a deauth attack, the attacker pretends to be the wireless router the device is connected to. The attacker disconnects the device from the network. When the user tries to reconnect, the attacker can intercept the user's information. Disassociation attacks are similar. Instead of disconnecting a user, disassociation tricks the user into giving the fake router responsibility for forwarding packets.

Rogue Access Points

A rogue access point is one that has been installed on the network without authorization, whether with malicious intent or not. A malicious user can set up such an access point with something as basic as a smartphone with tethering capabilities, and a non-malicious user could enable such an access point by accident. If connected to a local segment, an unauthorized access point creates a backdoor through which to attack the network.

A rogue access point masquerading as a legitimate one is called an evil twin. Each network is identified to users by a service set identifier (SSID) name. An evil twin might use typosquatting or SSID stripping to make the rogue network name appear similar to the legitimate one. Alternatively, the attacker might use some DoS technique to overcome the legitimate access point. In the latter case, they could spoof both the SSID and the basic SSID (BSSID). The BSSID is the MAC address of the access point's radio. The evil twin might be able to harvest authentication information from users entering their credentials by mistake and implement a variety of other on-path attacks, including DNS redirection.



Surveying Wi-Fi networks using MetaGeek inSSIDer. The Struct-Guest network shown in the first window is the legitimate one and has WPA2 security configured. The evil twin has the same SSID but a different BSSID (MAC address) and open authentication. (MetaGeek, Inc. © Copyright 2005-2023.)

A rogue hardware access point can be identified through physical inspections. There are also various Wi-Fi analyzers and wireless intrusion protection systems that can detect rogue access points. These can log the use of typosquatting SSIDs and unknown and duplicate (spoofed) MAC addresses. In an enterprise network, access points are usually connected to switches. Monitoring can detect any that are not and flag them as potential rogues. They may also be able to identify radio hardware and alert if an unauthorized access point brand is detected.

Bluetooth Attacks

Bluetooth is designed to allow devices to communicate within a personal area network (PAN) of close proximity. PAN devices include cell phones, personal digital assistants (PDAs), printers, mice, and keyboards.

Bluetooth:

- Is designed for distances longer than infrared (IR) communication and has lower power consumption.
- Requires that devices be in discovery mode to find each other and synchronize.
- Operates in the 2.4 GHz range and uses adaptive frequency hopping (AFH).

Eavesdropping is difficult because Bluetooth implements authentication and key derivation with custom algorithms based on the SAFER+ block cipher. It also uses the E0 stream cipher for encrypting packets. Bluetooth is one of the most secure protocols for mobile device communication, but it is susceptible to the following attacks:

Bluejacking looks for nearby devices that are in discovery mode and sends unwanted messages. The attacker is unable to steal any data. This attack is more annoying than harmful.

Bluesnarfing exploits a vulnerability in the object exchange (OBEX) protocol that allows an attacker to pair to the target device. Once paired, the attacker can view the calendar, emails, text messages, contact lists, and other data on the device. Many Bluetooth devices have built-in features to prevent bluesnarfing, but it is still a known vulnerability.

To mitigate the risks of Bluetooth attacks, enable Bluetooth only when needed and make sure discovery mode is turned off except when pairing devices.

RFID/NFC Attacks

RFID uses radio waves to transmit data from small circuit boards, called RFID tags, to special scanners. There are two types of RFID tags:

Active RFID tags have onboard batteries and can send signals over a long distance. Road toll passes and other types of passes use active RFID.

Passive RFID is not powered and relies on the energy of the scanner to transmit data. These tags are seen in ID badges, credit cards, and similar devices.

RFID systems are vulnerable to various kinds of attacks, including:

RFID Attack	Description
Eavesdropping	An attacker uses an RFID reader to listen to conversations between a tag and the intended reader.
Man-in-the-middle (MTM)	An attacker intercepts a signal from an RFID tag and then manipulates it before sending it to the intended recipient. This kind of attack is frequently used to take down a system.
Denial-of-service (DOS)	An attacker blocks radio signals or jams the system with interfering noise.
Cloning and spoofing	An attacker creates a copy of an existing tag and uses the fake tag to gain access to a secure system.

To protect against these attacks, RFID chips often operate at different frequencies. This makes it more difficult for an attacker to find and scan them.

Near Field Communication (NFC) is a newer technology that is built on RFID. NFC allows two-way communication between two devices. The devices must be within a few centimeters of each other. Although NFC transmission distances are very short, transmissions are susceptible to several malicious attacks, including:

A lost NFC device allows anyone who finds it to access NFC resources.

NFC signals can be jammed by malicious interference.

NFC devices and readers are susceptible to man-in-the-middle exploits, where an attacker captures transmissions from the reader and forwards them onto the device, potentially reading and modifying data in transit.

NFC devices and readers are susceptible to relay attacks. An attacker can capture NFC data in transit and use the information to masquerade as the original device.

8.5.3 Detecting Rogue Hosts (Demo Video)

Transcript:

In this demo, we're going to configure our wireless controller to detect rogue hosts and look at other features wireless controllers have. Some of these features help with rogue host detection. If you remember, a rogue host is an unauthorized access point within your network or a different network in the surrounding area.

Let's start by logging in to our controller. On the main page, we have some statistics that can be useful for seeing what's going on with your wireless networks. We're going to check to see if this controller is set up for detecting rogue hosts. Let's go to Insight > Untrusted Rogue APs. Notice there are no APs listed in this section. To populate this list, we're going to have to trigger a scan to look for these them.
Under Access Points, we're going to click the one access point we have. This first window shows details related to the access point. Now we're going to go to Configuration and see what kind of settings we have available for this AP.
IP Setting allows you to set DHCP or static addresses. If settings are set to DHCP, you can specify a failback IP address, MASK, and gateway. Radio gives you several options to tweak, such as mode, channel width, channel, and TX power. Some controllers have an auto mode for Tx power, but this one doesn't.
Load balance provides options for balancing connected clients. Max associated clients can be set so once that threshold is hit, load balancing is triggered. RSSI Threshold is a signal strength setting. If the client's signal is weaker than the set RSSI threshold, it'll disconnect the client from the AP. WLANs show which wireless networks are set up with this access point. You can override each access point if you don't want the same SSIDs on each access point. LED is just the indicator light on the access point.
The last setting we're going to look at is Rogue AP Detection. This is the scan button we use to scan for Rogue APs. Let's start a scan. Depending on how many surrounding networks there are, it could take several minutes. Great, the scan has completed. Let's go take a look at the list.
We're going to go back to insight and then to the Untrusted Rouge APs. This will show us some details related to information gathered during the scan. Let filter them so we know which APs are the closest by signal strength. You can see we have one AP that's close with -46 signal strength.
Sometimes, it's even possible to see the device's location on a map with other solutions. We have two options for rogue APs: we can trust them, or we can delete them from the list. The Tp-link Omada controller already knows that it's an untrusted AP, and it'll remain that way unless we trust it.
Let's say we know about this device, so we'll mark it as trusted. The device was removed from the untrusted list, and now it's on the Trusted APs list.
There could be a time where you may want to remove a trusted rouge AP and put it back on the untrusted list. To do that, you click the Untrust button. Now the SSID network NotYourWifi is back on the untrusted list.
It's important to know that this rogue device detection feature is just one step in protecting your network. If you were to identify a very suspect rogue device here, you would probably want to take additional steps, such as using an RF scanner to pinpoint the device and physically remove it from your organization or find the building where the network is coming from. Not all rogue APs are expected to be on your network, as other users may set up APs for their own use.
That's it for this demo. In this demo, we discussed the configuration of various features on a wireless controller. We looked at various settings we can control with an AP. We also looked at how you can manage rogue devices.

8.5.4 Configure Rogue Host Protection (Simulation)

Scenario

You are a network technician for a small corporate network. You want to take advantage of the self-healing features provided by the small enterprise wireless solution you've implemented. You're already logged in as WxAdmin on the Wireless Controller console from ITAdmin.

In this lab, your task is to:

Configure self-healing on the wireless network.

Automatically adjust AP radio power to optimize coverage when interference is present.

Set 2.4 GHz and 5 GHz radio channels to use the **Background Scanning** method to adjust for interference.

Configure the background scanning needed for rogue device detection, AP locationing, and self-healing. Background scans should be performed on all radios every **30 seconds** .

Configure load balancing for all radios by adjusting the threshold to **40 dB** .

Configure band balancing to allow no more than **30%** of clients to use the 2.4 GHz radios.

Reduce the power levels to **-3 dB** for three access points in Building A to reduce RF emanations. Use the wireless survey results in the exhibit to identify the access points.

The amount you reduce TX Power by requires a judgment call based on the wireless survey results. In practice, you would repeat the wireless survey to verify the proper TX Power settings.

Explanation

Complete this lab as follows:

Configure self-healing.

From the Ruckus ZoneDirector, select the **Configure** tab.

From the left menu, select **Services** .

From the right, under *Self-Healing,* select **Automatically adjust AP radio power to optimize coverage when interference is present** .

Using the *Automatically adjust 2.4GHz channels using* drop-down menu, select **Background Scanning** from the drop-down menu.

Using the *Automatically adjust 5GHz channels using* drop-down menu, select **Background Scanning** from the drop-down menu.

From the right of this section, select **Apply** .

Configure background scanning.

Under Background Scanning, select **Run a background scan on 2.4GHz radio** .

Enter **30** seconds.

Select **Run a background scan on 5GHz radio** .

Enter **30** seconds.

From the right of this section, select **Apply** .

Configure load balancing.

Under Client Load Balancing, select **Run load balancing on 2.4GHz radio** .

In the *Adjacent radio threshold(dB)* field, enter **40** .

Select **Run load balancing on 5GHz radio** .

In the *Adjacent radio threshold(dB)* field, enter **40** .

From the right of this section, select **Apply** .

Configure band balancing.

Under Band Balancing, select **Percent of clients on 2.4GHz radio** .

Enter **30** .

From the right of this section, select **Apply** .

Adjust the AP power level.

From the left menu, select **Access Points** .

From the top right, select **Exhibit** to determine which access points to adjust.

Select **Edit** next to the access point to be modified.

Under *Radio B/G/N(2.4G)* next to TX Power, make sure **Override Group Config** is selected.

From the *TX Power* drop-down list, select **-3dB (1/2)** .

Under *Radio A/N/AC(5G)* next to **TX Power** , make sure **Override Group Config** is selected.

From the *TX Power* drop-down list, select **-3dB (1/2)** .

Select **OK** .

Repeat steps 5b - 5h for additional access points.

8.5.5 Practice Questions (Section Quiz)

q_wl_attacks_bluejacking_secp8

Which of the following sends unsolicited business cards and messages to a Bluetooth device?

Answers:

***Bluejacking**

Bluesnarfing

Bluebugging

Slamming

Explanation:

Bluejacking is a relatively harmless practice that entails an unknown sender sending business cards anonymously to a Bluetooth recipient within a distance of 10-100 meters, depending on the class of the Bluetooth device. The business cards usually include a flirtatious message so the attacker can see a visual reaction from the recipient. Multiple messages are sent to the device if the attacker thinks there is a chance they will be added as a contact. Bluetooth devices are not susceptible to bluejacking if they are set to non-discoverable mode.

Bluesnarfing is the use of a Bluetooth connection to gain unauthorized access to an existing Bluetooth connection between phones, desktops, laptops, or PDAs. Bluesnarfing allows the attacker to view calendars, emails, text messages, and contact lists.

Bluebugging gives an attacker access to all mobile phone commands that use Bluetooth technology, such as initiating phone calls, sending and receiving messages, eavesdropping, and reading and writing phone book contacts.

Slamming entails unauthorized or fraudulent changes made to a subscriber's telephone service or DSL internet service.

q_wl_attacks_bluesnarfing_secp8

Which of the following BEST describes bluesnarfing?

Answers:

Sending anonymous electronic business cards

***Viewing calendar, emails, and messages on a mobile device without authorization**

Executing commands on a mobile device

Cloning a mobile device

Explanation:

Bluesnarfing is the use of a Bluetooth connection to gain unauthorized access to an existing Bluetooth connection between phones, desktops, laptops, or PDAs. Bluesnarfing allows access to view the calendar, emails, text messages, and contact lists. Many Bluetooth devices have built-in features to prevent bluesnarfing, but it is still a known vulnerability.

Bluejacking is a relatively harmless practice that entails an unknown sender sending business cards anonymously to a Bluetooth recipient within a distance of 10-100 meters, depending on the class of the Bluetooth device. The business cards usually include a flirtatious message so the attacker can see a visual reaction from the recipient. Multiple messages are sent to the device if the attacker thinks there is a chance they will be added as a contact. Bluetooth devices are not susceptible to bluejacking if they are set to non-discoverable mode.

Bluebugging gives an attacker access to all mobile phone commands that use Bluetooth technology, such as initiating phone calls, sending and receiving messages, eavesdropping, and reading and writing phone book contacts. Only highly skilled individuals can perform bluebugging.

q_wl_attacks_bluetooth_secp8

A large hospital uses Bluetooth technology for short-range personal area networking. The organization has a security concern with bluesnarfing.

What is the attacker doing to the organization?

Answers:

***Stealing information from someone else's phone by using an exploit in Bluetooth.**

Sending unsolicited text messages or vCards to a discoverable device.

Launching highly effective attacks using a peripheral device with malicious firmware.

Compromising any active and unpatched system, regardless of whether discovery is enabled.

Explanation:

Using an exploit in Bluetooth, bluesnarfing allows attackers to steal information from someone else's phone, circumventing the authentication mechanism and accessing sensitive information without the user's knowledge or consent.

Sending unsolicited text messages or vCards to a discoverable device is bluejacking, where an attacker sends an unsolicited message or contact details.

Connecting to malicious peripherals presents a risk of launching highly effective attacks using a peripheral device with malicious firmware. However, it is not specifically related to bluesnarfing.

The BlueBorne exploit compromises any active and unpatched system, regardless of whether the system enables discovery, compromising Bluetooth-enabled systems.

q_wl_attacks_emi_secp8

Which type of interference is caused by motors, heavy machinery, and fluorescent lights?

Answers:

RFI

NFC

***EMI**

RFID

Explanation:

Electromagnetic interference (EMI) is interference caused by motors, heavy machinery, and fluorescent lights.

Radio frequency interference (RFI) is interference on the radio channel. It is caused by nearby wireless devices using the same channel, cordless phones, or microwave ovens.

Near frequency communication (NFC) allows two-way communication between two devices. The devices must be within a few centimeters of each other.

Radio frequency identification (RFID) uses radio waves to transmit data from small circuit boards, called RFID tags, to special scanners.

q_wl_attacks_evil_twin_secp8

Which of the following BEST describes an evil twin?

Answers:

***An access point configured to mimic a valid access point to obtain logon credentials and other sensitive information.**

A threat agent that marks the outside of buildings to indicate the presence of a wireless network.

An access point that is added to a network by an internal employee to provide unauthorized network access.

A Bluetooth device that receives mobile phone commands via bluebugging.

Explanation:

An evil twin is a rogue access point configured to mimic a valid access point. In contrast, a rogue access point is any unauthorized access point added to a network. The evil twin may be configured to prompt for credentials, allowing the attacker to steal those credentials or use them in a man-in-the-middle attack to connect to the valid wireless access point.

Warchalking is marking the outside of buildings to indicate the presence of a wireless network. Attackers might use these marks to alert others of open or secured wireless networks. Businesses might even use these marks to advertise free wireless networks.

Bluebugging gives an attacker access to all mobile phone commands that use Bluetooth technology, such as initiating phone calls, sending and receiving messages, eavesdropping, and reading and writing phone book contacts. Only highly skilled individuals can perform bluebugging.

q_wl_attacks_iv_secp8

Which type of attack is WEP extremely vulnerable to?

Answers:

***IV attack**

Evil twin

Bluesnarfing

Cloning

Explanation:

Wired Equivalent Privacy (WEP) is extremely vulnerable to initialization vector (IV) attacks because WEP reuses the IVs. This makes it easy for attackers to crack them and compromise the encryption.

An evil twin attack is a type of rogue access point attack.

Bluesnarfing is a Bluetooth attack.

Cloning is an RFID attack.

q_wl_attacks_jamming_secp8

You are the security analyst for your organization. Clients are complaining about being unable to connect to the wireless network. After looking into the issue, you have noticed short bursts of high-intensity RF signals are interfering with your wireless network's signal.

Which type of attack are you MOST likely experiencing?

Answers:

Disassociation

***Jamming**

Bluesnarfing

Cloning

Explanation:

In a jamming attack, a transmitter is tuned to the same frequency and type of modulation as the wireless network. The jamming signal overrides the legitimate wireless network radio signals. This scenario is a spark jamming attack.

A disassociation attack occurs when a user is tricked into giving a fake router responsibility for forwarding packets.

Bluesnarfing is a Bluetooth attack.

Cloning is an RFID attack.

q_wl_attacks_nfc_01_secp8

An attacker has intercepted near-field communication (NFC) data and is using that information to masquerade as the original device.

Which type of attack is being executed?

Answers:

Disassociation

Bluesnarfing

Cloning

***Relay**

Explanation:

This scenario describes a relay attack. A relay attack occurs when an attacker can capture NFC data in transit and use the information to masquerade as the original device.

A disassociation attack occurs when a user is tricked into giving a fake router responsibility for forwarding packets. This is not performed on NFC devices.

Bluesnarfing is a Bluetooth attack.

Cloning occurs when an attacker creates a copy of an existing RFID tag and uses the fake tag to gain access to a secure system.

q_wl_attacks_nfc_02_secp8

A cybersecurity analyst is implementing security measures for Near Field Communication (NFC) usage in the organization's mobile devices.

Which technique should the analyst consider applying to mitigate potential risks associated with NFC technology?

Answers:

Enable NFC chip reading for all devices to enhance connectivity options.

Use NFC for direct payment transactions without the need for mobile wallet apps.

***Apply encryption to NFC data to prevent eavesdropping and on-path attacks.**

Increase the NFC signal range to improve communication.

Explanation:

Applying encryption to NFC data is crucial to prevent eavesdropping and on-path attacks, ensuring that sensitive information remains secure during communication.

Enabling NFC chip reading for all devices may increase connectivity options, but it can also expose them to potential risks and unauthorized access.

q_wl_attacks_rfid_secp8

Which type of RFID tag can send a signal over a long distance?

Answers:

Passive

***Active**

NFC

Bluetooth

Explanation:

Active RFID tags have onboard batteries and can send signals long distances. Road toll passes and other types of passes use active RFID.

Passive RFID is not powered and relies on the energy of the scanner to transmit data. These tags are seen in ID badges, credit cards, and similar devices.

NFC allows two-way communication between two devices. The devices must be within a few centimeters of each other.

Bluetooth is designed to allow devices to communicate within a personal area network of close proximity.

q_wl_attacks_rogue_01_secp8

Your company security policy states that wireless networks are not to be used because of the potential security risk they present to your network.

One day, you find that an employee has connected a wireless access point to the network in his office.

Which type of security risk is this?

Answers:

***Rogue access point**

Man-in-the-middle attack

Phishing

Physical security

Social engineering

Explanation:

A rogue access point is an unauthorized access point added to a network, or it is an access point that is configured to mimic a valid access point. Examples include:

- An attacker or an employee with access to the wired network installs a wireless access point on a free port. The access port then provides a way to access the network remotely.
- An attacker near a valid wireless access point installs an access point with the same (or similar) SSID. The access point is configured to prompt for credentials, allowing the attacker to steal those credentials or use them in a man-in-the-middle attack to connect to the valid wireless access point.
- An attacker configures a wireless access point in a public location and then monitors traffic to see who connects to the access point.

A man-in-the-middle attack is used to intercept information passing between two communication partners. A rogue access point might be used to initiate a man-in-the-middle attack. But in this case, the rogue access point was connected without malicious intent. Social engineering exploits human nature by convincing someone to reveal information or perform an activity. Phishing uses an email and a spoofed website to gain sensitive information.

q_wl_attacks_rogue_02_secp8

A user contacts a company help desk complaining about intermittent connection problems to needed network files and shares. The user also noticed connection problems occur when the network signal strength is at its highest.

What could this be a sign of? (Select two.)

Answers:

***Rogue access point**

***Wireless denial-of-service**

Wireless replay

Downgrade attack

RFID attack

Explanation:

A rogue access point (AP) allows a person with malicious intent to place a rogue AP with a higher power to capture usernames and passwords without getting caught immediately.

A wireless denial-of-service attack causes network problems by not allowing users access to legitimate APs due to the rogue AP's higher signal strength.

A wireless replay attack aims to capture the hashes used when a wireless station associates with an access point. Then, the hash gets subjected to attacks to crack the encryption. It does not impact wireless access.

A downgrade attack attempts to make a server or client use a lower specification protocol with weaker ciphers and key lengths. It does not impact wireless access.

RFID uses radio waves to transmit data from small circuit boards, called RFID tags, to special scanners. It does not impact wireless access to network files and shares.

q_wl_attacks_site_survey_secp8

You are concerned that wireless access points may have been deployed within your organization without authorization.

What should you do? (Select two. Each response is a complete solution.)

Answers:

***Conduct a site survey.**

***Check the MAC addresses of devices connected to your wired switch.**

Implement an intrusion detection system (IDS).

Implement an intrusion prevention system (IPS).

Implement a network access control (NAC) solution.

Explanation:

A rogue host is an unauthorized system connected to a wireless network. It could be an unauthorized wireless device, or it could even be an unauthorized wireless access point that someone connected without permission to a wired network jack. Rogue hosts could be benign in nature, or they could be malicious. Either way, rogue hosts on your wireless network could represent a security risk and should be detected and removed if necessary. Four commonly used techniques for detecting rogue hosts include:

Using site survey tools to identify hosts and APs on the wireless network

Checking connected MAC addresses to identify unauthorized hosts

Conducting an RF noise analysis to detect a malicious rogue AP that is using jamming to force wireless clients to connect to it instead of legitimate APs

Analyzing wireless traffic to identify rogue hosts

Using an IDS or an IPS would not be effective, as these devices are designed to protect networks from perimeter attacks. Rogue APs are internal threats. A NAC solution can be used to remediate clients that connect to a network, but a NAC solution can't be used to detect a rogue AP.

q_wl_attacks_wpa3_secp8

A company's IT security specialist decides to upgrade the wireless network infrastructure to enhance data protection during transmissions. Recognizing the importance of strong encryption for wireless data, the specialist evaluates the various encryption standards available.

Which wireless encryption standard offers the MOST robust security for protecting wireless data transmissions and has become the preferred choice for many organizations?

Answers:

***WPA3**

WEP

WPA

TKIP

Explanation:

Wi-Fi Protected Access 3 (WPA3) enhances security beyond its predecessors and is the most robust wireless data protection encryption standard. It rectifies vulnerabilities found in WPA2 and WPA and represents the latest standard.

People view wired equivalent privacy (WEP) as a dated wireless encryption standard and deem it weak due to its identifiable vulnerabilities. It does not measure up to WPA3 in security.

TKIP is a WLAN encryption protocol designed to provide more secure encryption than WEP. However, it does not provide the same level of security as WPA3.

8.6 Wireless Defenses

As you study this section, answer the following questions:

- Which settings in a wireless access point can you configure to improve security?
- Which cryptographic protocol uses a Remote Authentication Dial-In User Service (RADIUS) server?
- Which access method forces a user to view and interact with it before accessing a network?
- What are the three components in an 802.1x setup?
- Which EAP standard is considered to be one of the most secure?

In this section, you will learn to:

- Harden a wireless network.
- Configure a wireless intrusion prevention system.

The key terms for this section include:

Term	Definition
Wi-Fi Protected Access (WPA)	The most commonly used cryptographic protocol in use for wireless networks. WPA2 and WPA3 are the two versions in use.
Pre-shared key (PSK)	Wireless access method that utilizes a passphrase for users to connect.
Wi-Fi Protected Setup (WPS)	Wireless access method that allows a device to securely connect to a wireless network without typing the PSK.
Open network	Wireless access method that has no authentication.
Captive portal	Wireless access method that forces a user to view and interact with it before accessing a network.
802.1x	Standard for local area networks that is used to authenticate users to a wireless network. It was created by The Institute of Electrical and Electronics Engineers Standards Association (IEEE-SA).
Remote Authentication Dial-In User Service (RADIUS)	A protocol used to authenticate users in a enterprise environment to a wireless network.

Extensible Authentication Protocol (EAP)	An authentication framework that uses a set of interface standards. EAP allows various authentication methods to be used.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.2 Explain common threat vectors and attack surfaces. Unsecure networks Wireless Default credentials 2.3 Explain various types of vulnerabilities. Hardware Firmware 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Hardening techniques Default password changes 3.2 Given a scenario, apply security principles to secure enterprise infrastructure. Infrastructure considerations Network appliances Intrusion prevention system (IPS)/intrusion detection system (IDS) Port security 802.1X Extensible Authentication Protocol (EAP) Secure communication/access Tunneling

	Transport Layer Security (TLS) 4.1 Given a scenario, apply common security techniques to computing resources. Wireless devices Installation considerations Wireless security settings Wi-Fi Protected Access 3 (WPA3) Cryptographic protocols AAA/Remote Authentication Dial-In User Service (RADIUS) Authentication protocols
TestOut Security Pro	2.2 Harden Network Devices 2.2.2 Configure and Access a Wireless Network 2.2.4 Harden a Wireless Network

8.6.1 Wireless Security (Lesson Video)

Transcript:

Wireless networking uses radio frequencies to transmit data. This means that anyone with a wireless receiver can capture data from a network if it's not secured properly. In this lesson, we'll go over some common configuration problems and different cryptographic protocols we can implement to further secure our data.

When we set up a new wireless access point, the first thing we need to do is properly configure it. Many users just plug it in and use the default settings, which is extremely dangerous. These settings are readily available for anyone to look up on the internet.
The first setting to change is the default login information. All access points are shipped with a default login, such as admin. No other setting matters more than this one because if an attacker has our login information, they basically have complete control of the whole device.
The next setting we should change is the network name, or SSID, which stands for service set identifier. The SSID can be a maximum of 32 bytes in length. We want to make sure that our SSID is unique to ourselves, but it shouldn't include identifiable information such as last name or address.
By default, the SSID is broadcast, and anyone within range can see the network name. We can, though, disable this right from the start if we choose. This might seem like an obvious setting to enable, but it doesn't actually provide as much security as you'd think. A determined hacker can easily discover hidden SSIDs, and beyond that, disabling the SSID can cause connection issues for your device. You should experiment to see if disabling your SSID is the best option for your network.
You can also configure your wireless access point to use MAC address filtering. This makes it so only hosts that have certain MAC addresses can connect, which helps you control which systems are allowed access in the first place. MAC address filtering provides a minimal level of security at best, though. It may discourage a casual attacker, but it won't stop a determined one.
If an attacker is really set on gaining access to your wireless network, they can sniff packets and see which MAC addresses are being used to connect to the wireless access point. Then they can use MAC address spoofing to configure their system with one of the allowed MAC addresses.
You should also monitor your wireless access point antenna placement and wireless access point antenna power levels.

Data emanation is a significant security problem. By default, the radio signals used by a wireless network broadcast omni-directionally. That radio signal travels farther than you realize, which makes it possible for an attacker outside of your building to access your wireless network. You can limit this exposure by manipulating your wireless access point antenna placement and your wireless access point power levels to reduce the amount of data emanation outside of the building.

Proper access point configuration is important to keeping a wireless network safe. But the most important security step is choosing the correct encryption method. Using a weak encryption method like WEP would make a network vulnerable to any hacker.

When we configure our wireless network, it's important that we select the best cryptographic protocols available. For most users, the Wi-Fi Protected Access, or WPA, versions 2 or 3 are the best options.

WPA2 was first introduced in 2004 and is still widely used today. There are two versions availableâ€”WPA2-Personal and WPA2-Enterprise. WPA2-Personal, also known as WPA2-PSK, or WPA2 pre-shared key, protects our network by using a pre-shared key referred to as the passphrase. WPA2-Enterprise verifies users through a RADIUS server.

WPA2-Personal uses AES with CCMP to encrypt all data. This stands for Advanced Encryption Standard with Counter Mode Cypher Block Chaining Message Authentication Code Protocol. AES with CCMP uses a 128-bit key and encrypts data in 128-bit blocks.

When a device connects to the access point, a four-way handshake occurs to authenticate the device. The pre-shared key and SSID are used to generate a session key during this process. A hacker can take advantage of some vulnerabilities in the four-way handshake to intercept the data and perform offline password attacks that could eventually crack weak passwords.

To address these vulnerabilities and support new technologies, the WPA3 standard is being implemented. WPA3 was introduced in 2018. Instead of using a pre-shared key, WPA3 uses the Simultaneous Authentication of Equals standard, or SAE standard.

SAE uses a 128-bit key and perfect forward secrecy to authenticate. Perfect forward secrecy is a cryptographic method that generates a new key for every transmission. This makes the handshake much more secure because if a hacker gets ahold of one message, they still aren't able to crack the keys.

It'll take a while for WPA3 to fully replace WPA2 since WPA2 is currently implemented in many network devices. Until then, we need to be aware of the differences in these standards and their encryption method vulnerabilities so that we can better protect our networks.

That'll wrap up this lesson. In this lesson, we looked at some things we can do to better secure out wireless networks. We first looked at some of the default configurations we should change, including login information, the SSID, MAC address filtering, and transmission power. Then we looked at the two main cryptographic protocols in use today, which are WPA2 and WPA3. WPA2 is still the most widely used protocol, but WPA3 has been released and will eventually fix many of the vulnerabilities inherent in WPA2.

8.6.2 Wireless Security Facts

Wireless networking uses radio frequencies to transmit data. This means anyone with a wireless receiver can capture data from an improperly secured network.

This lesson covers the following topics:

- Weak configurations
- Cryptographic protocols

Weak Configurations

Proper configuration of a wireless access point (WAP) is the first step in securing the network. The following table explains some important actions to take regarding WAP settings.

Security Configuration Action	Description

Change default login credentials	WAPs typically come configured with a default administrator username and password. Because the administrator username and password are used to configure WAP settings, it's important to reset the defaults. This prevents outsiders from guessing the default username and password and breaking into the system.
Change default service set identification (SSID) and broadcast	The SSID can be a maximum of 32 bytes in length. Since many manufacturers use a default SSID, it's important to change the SSID from the default. The SSID should be unique but should not contain identifiable information (address, last name, etc.). The SSID broadcast can also be disabled. This is known as SSID suppression or cloaking. A determined hacker can still easily discover hidden SSIDs. Disabling the SSID broadcast can cause connection issues for devices.
Enable MAC address filtering	Every network device has a unique media access control (MAC) address. By specifying the MAC addresses allowed to connect to the network, unauthorized MAC addresses can be prevented from connecting to the WAP. Configuring a MAC address filtering system is very time-consuming and demands upkeep. Attackers can still use tools to capture packets and retrieve valid MAC addresses. An attacker can spoof a wireless adapter's MAC address and circumvent the filter.
Update the firmware	Manufacturers release updates to the firmware on a regular basis to address known issues. It is important to regularly check for updates and apply them to prevent the system from being exposed to known bugs and security vulnerabilities. While it is extremely important to keep devices up-to-date, it's just as important to properly test new updates before pushing them out to the entire network. Proper testing will reduce the number of new bugs or problems on a live network that the update may have introduced.
Enable the WAP firewall	Most wireless APs come with a built-in firewall that connects the wireless network to a wired network. This should be enabled to help prevent unauthorized access to the network.
Wi-Fi signal strength	Data emanation is a significant security problem. By default, the radio signals used by a wireless network are broadcast omnidirectional and can travel quite a distance from the WAP. An attacker sitting outside the building may be able to connect to the wireless network if the signal is traveling outside. This can be limited by manipulating the WAP antenna placement. Some WAPs also allow the signal strength to be adjusted. These settings reduce the signal strength, so the signal stays inside the building.

Cryptographic Protocols

Enabling the proper cryptographic protocol is perhaps the most important way to secure a wireless network. For most users, Wi-Fi Protected Access (WPA) versions 2 or 3 will be the best option. The following table explains these two protocols:

Cryptographic Protocol	Description
Wi-Fi Protected Access 2 (WPA2)	WPA2 is the implementation name for wireless security that adheres to the 802.11i specifications. It was first introduced in 2004 and is still heavily used in today's networks. There are two versions of WPA2 available: WPA2-Personal is also known as WPA2-PSK (pre-shared key). This version uses a pre-shared key, or passphrase, to protect the network. WPA2-PSK: Uses Advanced Encryption Standard with Counter Mode with Cipher Block Chaining Message Authentication Code Protocol (AES-CCMP)as the encryption algorithm to encrypt all data. AES-CCMP uses a 128-bit key and a 128-bit block size. Performs a 4-way handshake to authenticate the device when it connects to the access point. The pre-shared key and SSID are used to generate a session key during this process. The handshake does have some vulnerabilities that allow a hacker to intercept data and perform offline password attacks. WPA2-Enterprise uses a RADIUS server to authenticate users to the network.
Wi-Fi Protected Access 3 (WPA3)	To support the vulnerabilities inherent in the WPA2 handshake and to support newer technologies, WPA3 was implemented. First introduced in 2018, WPA3 implements the Simultaneous Authentication of Equals (SAE) standard instead of using the pre-shared key. SAE uses a 128-bit key and Perfect Forward Secrecy (PFS) to authenticate users. Perfect forward secrecy is a cryptography method that generates a new key for every transmission. This makes the handshake much more secure from hackers. If any portion of the handshake is intercepted, the key is still uncrackable.

8.6.3 Wireless Authentication and Access Methods (Lesson Video)

Transcript:

Wireless networks encrypt communications using a security protocol, which is typically WPA2 or WPA3. But in order to authenticate users and distribute authentication keys, other methods are generally used. In this lesson, we'll go over some of the different access methods we can implement to connect to a wireless network as well as the authentication protocols we often find in enterprise environments.

Depending on the environment, we can use different methods to connect users to a wireless network. Let's take a look at some of these methods.
The first and probably most common access method is to use a pre-shared key, or PSK. A PSK is simply a passphrase that we type in to connect to a network. If we don't want to type in the passphrase to connect each and every device, we can use Wi-Fi Protected Setup, or WPS, to simplify the process.
WPS only works with a network that uses a pre-shared key and WPA2. On the access point, there's usually a button that makes WPA2 start to search for devices in range. On the connecting device, there's probably a WPS button that automatically joins the device to the access point. You need to enter a unique eight-number access point pin if the connecting device doesn't have a button like this. Some devices and access points can also use Near Field Communication, or NFC, during the WPS process to connect to each other.

Our other option is to simply have an open network. This means that no authentication takes place, and anyone can connect to the network at will. This should only be used by public establishments that want to offer free wireless access. Many open networks implement a captive portal. Captive portals force a user to view and interact with them before accessing the network. Basically, you're initially able connect your device to the wireless network. But before you can access the internet, you're redirected to a captive portal page. You might be prompted to agree to the network's terms and conditions or maybe even asked to pay a fee before you can proceed. These portals are used a great deal today, and you've most likely used one before.

In an enterprise environment, using a PSK isn't very secure or efficient. Enterprise networks usually make use the 802.1x Protocol to authenticate users to the wireless network.

802.1x authentication is one of the most secure ways to enforce wireless network authentication. On a wired network, once a user is authenticated, the port they're connected to is activated. The port remains off if the user's activation fails. We can implement the 802.1x Protocol in a wireless network by enabling a virtual port when the user is authenticated. There are three components to an 802.1x setup. The first is the supplicant, or wireless client. Then we have the authenticator, which is responsible for handling the communications between the supplicant and the authentication serverâ€”the third component. Know that oftentimes, the authentication server is a RADIUS server. When you use a RADIUS server, the authenticator is also known as the network access server, or NAS.

RADIUS stands for Remote Authentication Dial-In Service. It was developed in 1991 and was originally used to authenticate users to remote networks over dial-up networks. We still use it today to remotely authenticate users. Obviously, though, we don't do this over dial-up connections anymore, which are more or less antiquated. RADIUS is known as a triple-A protocol, meaning that it provides authentication, authorization, and accounting management.

When using 802.1x with RADIUS, the client sends their credentials to the authenticator, or NAS. The NAS forwards the credentials to the RADIUS server to verify. If you use a Windows server, this is done using Active Directory. Then the server sends back the verification and user rights to the NAS, which forwards them back to the client. Then the client can access network resources. Using 802.1x authentication significantly increases your wireless network security.

To ensure that the authentication information being sent between these devices is secure, the Extensible Authentication Protocol, or EAP, is used. EAP isn't actually a specific protocol; it's merely a framework in which other protocols work. As a security administrator, you need to be familiar with several different EAP protocols. Let's start by looking at the Protected Extensible Authentication Protocol, or PEAP.

PEAP was created collaboratively by Cisco, Microsoft, and RSA Security. This protocol encapsulates the authentication communications within a TLS tunnel and exclusively uses a server-side certificate to authenticate Wi-Fi clients. This simplifies network implementation and administration.

Next, we have EAP Flexible Authentication via Secure Tunneling, or EAP-FAST. EAP-FAST was created by Cisco, and it works by making a TLS tunnel that doesn't require an authentication server certificate. Instead, this protocol uses a Protected Access Credential, or PAC, to authenticate users.

Then, we have EAP Transport Layer Security, or EAP-TLS. EAP-TLS is the original and probably most secure of the wireless EAP authentication protocols. Because it's the original, it's also the most widely supported.

The nice thing about EAP-TLS is that it requires client-side certificates in addition to server-side certificates. The certificate fully encrypts the authentication handshake between client and server and is then used in place of a password, making it practically impossible to crack. But because each client
requires an installed CA-signed PKI certificate, EAP-TLS is much more labor intensive and expensive to implement than other protocols.

The final protocol is EAP Tunneled Transport Layer Security, or EAP-TTLS. EAP-TTLS is essentially an updated version of EAP-TLS. The biggest difference is that we only need a certificate on the server. This greatly simplifies the implementation process since we don't need a certificate on each wireless device. EAP-TTLS has been supported natively since Windows 8. By using the right authentication protocol, you can greatly increase your wireless network's security and further protect it from attacks.

That'll wrap up this lesson. In this lesson, we looked at the different wireless network access methods we can implement, including pre-shared keys, server authentication, and open networks. We also went over how WPS and captive portals work. Then we saw the various authentication methods that can be used for wireless networks. First, we looked at RADIUS and how it utilizes 802.1x authentication. We finished up by looking at the different EAP protocols, which include PEAP, EAP-FAST, EAP-TLS, and EAP-TTLS.

8.6.4 Wireless Authentication and Access Methods Facts

This lesson covers the following topics:

Access methods

Port security

MAC filtering and MAC limiting

Access Methods

Choose an access method for a wireless network based on the use of the network. The following table describes access methods:

Access Method	Description
Pre-shared key (PSK)	A pre-shared key is a passphrase used to access the wireless network. This is probably the most commonly used access method.
Wi-Fi Protected Setup (WPS)	Wi-Fi Protected Setup works only on a network that uses a PSK and WPA2. WPS allows a device to securely connect to a wireless network without typing in the PSK. To do this, you: Push a button on the access point that causes the access point to search for devices in range. Push the WPS button on the device to automatically join it to the access point. If there is no button, enter the eight-digit pin unique to the access point. Some devices and access points can also use Near Field Communication (NFC) during the WPS process to connect to each other.
Open network	An open network has no authentication at all and allows anyone to connect to the network. This access method should be used only in public places that want to offer free wireless access.
Captive portal	Many open networks implement a captive portal. Captive portals force a user to view and interact with them before accessing a network. A hotel network is a good example of captive portal use. When using a captive portal: The user connects to the wireless network but is redirected to a captive portal page before internet access is granted. The user might be prompted to agree to the terms and conditions of using the network or even asked to pay a fee before being granted access.

To ensure the authentication information being sent is secure, the Extensible Authentication Protocol (EAP) is used. EAP is a framework in which other protocols work. The following table explains EAP and the protocols:

Protocol	Description

Extensible Authentication Protocol (EAP)	EAP is a set of interface standards that allows various authentication methods to be used: • EAP supports multiple authentication methods (smart cards, biometrics, and digital certificates). • Using EAP, the client and server negotiate the characteristics of authentication.
Protected Extensible Authentication Protocol (PEAP)	PEAP provides authentication in an SSL/TLS tunnel with a single certificate on the server. PEAP: • Creates a secure communication channel for transmitting certificate or login credentials. • Enables mutual authentication by requiring the server to prove its identity to the client. • Was a collaborative effort between Cisco, Microsoft, and RSA.
EAP Flexible Authentication via Secure Tunneling (EAP-FAST)	EAP-FAST uses a Protected Access Credential (PAC) to authenticate users. EAP-FAST: • Establishes a TLS tunnel in which client authentication credentials are transmitted. • Is susceptible to attackers who intercept the Protected Access Credential (PAC) and use it to compromise user credentials. This vulnerability is mitigated by manual PAC provisioning or by using server certificates. • Was created by Cisco.
EAP Transport Layer Security (EAP-TLS)	EAP-TLS uses Transport Layer Security (TLS) and is considered one of the most secure EAP standards available. EAP-TLS: • Is widely supported by almost all manufacturers of wireless LAN hardware and software. • Requires signed client-side and server-side certificate authority (CA) PKI certificates. • Is labor-intensive and expensive to implement.
EAP Tunneled Transport Layer Security (EAP-TTLS)	EAP-TTLS also uses a CA signed certificate. EAP-TTLS: • Is an updated version of EAP-TLS. • Requires only one CA signed certificate on the server, simplifying the implementation process.

Port Security

Each wall and switch port represents an opportunity for a threat actor to attach a device to the network. A threat actor who can operate a host with physical access to a network segment can launch a variety of attacks.

Access to the physical switch ports and switch hardware should be restricted to authorized staff. To accomplish this, place the switch appliances in secure server rooms and lockable hardware cabinets. To prevent the attachment of unauthorized client devices at unsecured wall ports, the switch port that the wall port cabling connects to can be administratively disabled, or the patch cable can be physically removed from the switch port. Completely disabling ports in this way can introduce a lot of administrative overhead and allow room for error. Also, it doesn't provide complete protection, as an attacker could unplug a device from an enabled port and connect their own machine. Consequently, more sophisticated methods of ensuring port security have been developed.

MAC Filtering and MAC Limiting

The network adapter in each host computer is identified by a MAC address. Configuring MAC filtering means a switch port only permits certain MAC addresses to connect. This can be done by creating a list of valid MAC addresses or by specifying a limit to the number of permitted addresses. For example, if port security is enabled with a maximum of two MAC addresses, the switch will record the first two MACs to connect to that port. The switch then drops any traffic from machines with different MAC addresses that try to connect.

Restricting access by MAC address is difficult to manage and still prone to spoofing. Better security is obtained by forcing computers and users to authenticate before full network access is granted. The IEEE 802.1X Port-based Network Access Control (P NAC) standard allows a switch to require authentication when a host connects to one of its ports. 802.1X uses authentication, authorization, and accounting (AAA) architecture:

Supplicant - is the device requesting access, such as a user's PC or laptop.

Authenticator - is the switching device (or any type of network access appliance). This does not validate authentication request s directly but acts as a conduit for authentication data.

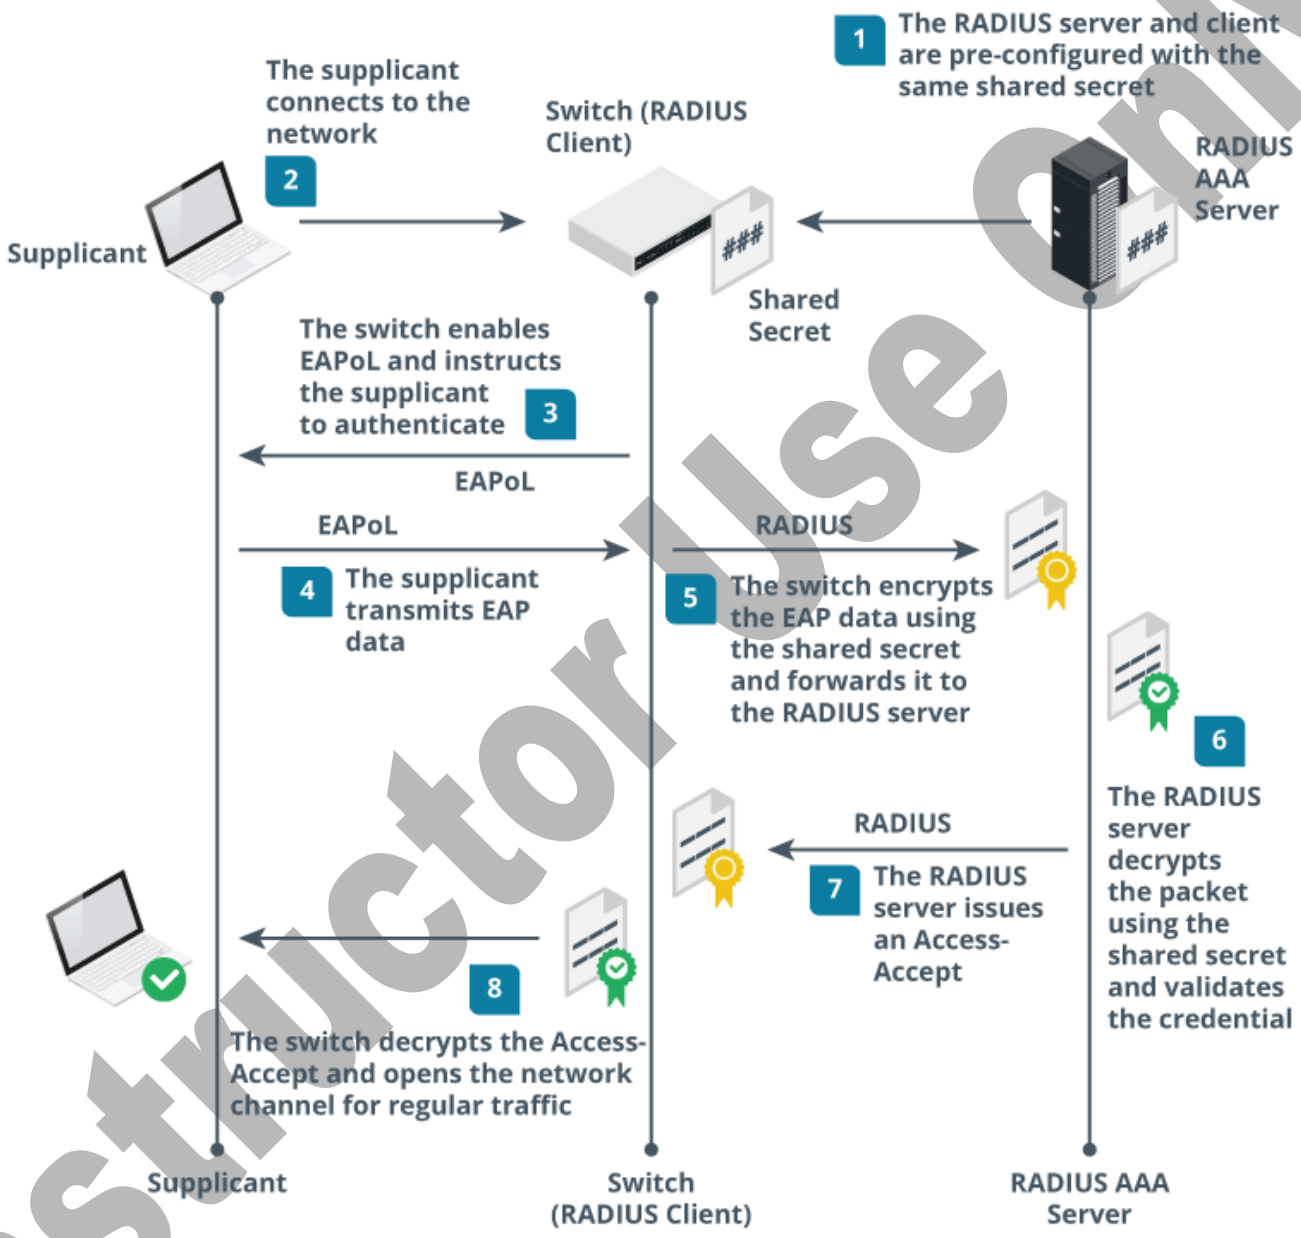
Authentication server - the server that holds or can contact a directory of network objects and validate authentication requests, issue authorizations, and perform accounting of security events.

The 802.1X standard is implemented by two protocols:

Extensible Authentication Protocol (EAP) - provides a framework for deploying multiple types of authentication methods. It is often used with digital certificates to establish a trust relationship and create a secure tunnel to transmit the user credential or to perform smart-card authentication without a password.

Remote Authentication Dial-In User Service (RADIUS) - allows the authenticator and authentication server to communicate authentication and authorization decisions. The authenticator is a RADIUS client; the authentication server is a RADIUS server.

When a host connects to an 802.1X-enabled switch port, the switch opens the port for the EAP over LAN (EAPoL) protocol only. The switch port only allows full data access when the host has been authenticated. The switch receives an EAP packet with the supplicant's credentials. These are encrypted and cannot be read by the switch. The switch uses the RADIUS protocol to send the EAP packet to the authentication server. The authentication server can access the directory of user accounts and can validate the credential. If authentication is successful, it informs the switch that full network access can be granted.



IEEE 802.1X Port-based Network Access Control with RADIUS and EAP authentication. (Images © 123RF.com.)

Some hosts are so security-critical that it is unsafe to connect them to any type of network. One example is the root certification authority in PKI. Another example is a host used to analyze malware execution. A host not physically connected to any network is said to be air-gapped .

It is also possible to configure an air-gapped network. This means that hosts within the air-gapped network can communicate, but there is no cabled or wireless connection to any other network. Military bases, government sites, and industrial facilities use air-gapped networks.

Physically isolating a host or group of hosts improves security but also incurs significant management challenges. Device administration has to be performed at a local terminal. Any updates or installs have to be performed using USB or optical media. This media is a potential attack vector and must be scanned before allowing its use on an air-gapped host.

8.6.5 Hardening a Wireless Access Point (Demo Video)

Transcript:

In this demonstration, we're going to go through some ofÂ the steps you can take to harden a wireless network, andÂ we're going to use a wireless controller.

This means we make changes on the controllerÂ itself, and those changes propagate out to eachÂ of the access points connected to it.Â The concepts in this demo transfer toÂ other types of wireless access points, such asÂ all-in-one small office/home office devices.
To start, we need to log in to our controller.Â I have a web browser open, and I've entered the controller's IP address. I'll enterÂ the username, â€˜admin', and password, and we're logged in.
The first thing we want to do is change theÂ default username and password for this device.Â This is the first thing you should do withÂ any networking device you're configuring.Â It's very important that you change those defaults.
We do this on the Administer tab.Â Notice we can also choose to use anÂ authorization server if we want to, but justÂ change the default username to something else.Â We'll enter the old password and then the new password.Â Click Apply. The Admin session timeout setting is also on this page.
This setting defines how much time must passÂ before the user is automatically logged out.
This is a nice thing to have, as it keeps users from logging in to the device andÂ then walking away from it and leaving it vulnerable.Â Let's change this to 10 minutes.Â Click Apply.
Now we're asked to log out and start aÂ new session with the new timeout setting.Â Click OK, and let's log in withÂ our new username and password.
Let's go to the Configure tab.Â There are a lot of settings and options on this tab.Â On the System tab, we can specify the IPÂ address and subnet mask to use on the network.
It's good to change this from a typical IPÂ address range, as it adds another layer ofÂ security, but we'll leave it how it is for now.Â Let's go to the Access Points page.
On this page, we can see all the accessÂ points connected to the wireless controller.
Right now, we only have one AP, or access point, connected.Â If we wanted to, we could clickÂ Edit and change the configuration.
Notice that all these options requireÂ us to override the group configuration.Â Remember, this is a wireless controller.Â As such, it controls the configurationÂ options for each access point in the network.
If we want to change the settings on aÂ specific access point (for example, change theÂ channel it's using), we can do that here.Â For now, let's click Cancel.
Under Access Point Groups, any changes to thisÂ configuration will be applied to all the APs in the network.Â This makes managing networks with multiple APs very easy.Â All the settings look good, so let's just click Cancel.
On the WLANs page, we can create wirelessÂ LANs--that is, we can create multipleÂ wireless networks, each specified by an SSID.Â For example, we currently have threeÂ different WLANs configured on this controller.Â Let's edit the DevRuckusAP network.
Here, we can see the configuration of this networkÂ and that it's defined as a standard network.Â We can also configure the authentication options.Â Right now, the authenticate type is open.
We could configure this to connect to a RADIUSÂ server, specify that it use MAC addressÂ authentication, or use a combination of the two.Â We can also configure the encryption method.
We're using WPA2 with the AES algorithm.Â You can see we have a very weak passphrase configured,Â which is fine for a demo, but make sure you use a complex passphrase with this encryption.
Down here, we can also configureÂ the WLAN to use a captive portal.Â The Wireless Client Isolation option allows us toÂ configure the network to isolate each connected client.

There are also a lot of advanced options we won't getÂ into, but remember there's a lot of customization thatÂ can happen with these types of wireless controllers thatÂ you just can't find in smaller, consumer-grade devices.Â Leave everything as it is and click Cancel.
Let's look at the configuration of the Guest network.Â Notice the type is defined as Guest, which causes our guestÂ access policies and access control settings to be applied.
We also need to note that we're using openÂ authentication with no encryption.Â This is an open, unsecure guest network.Â That's why we're isolatingÂ wireless client traffic from each other.Â It's good idea to have thisÂ option enabled on guest networks.Â Click Cancel, and let's go to the Access Control page.
On this page, we can configureÂ how client access is controlled.Â For example, under L2-L7 Access Control, we can define MACÂ address control lists that can be used with a specific WLAN.
To define MAC address control lists, add all the MACÂ addresses you want to give network access to and then enableÂ MAC address filtering on the specific WLAN to use that list.Â We can also do this by IP address.
Under Device Access Policy, we can permit or denyÂ clients based on their device specifications.Â For example, we could deny all clientsÂ using a particular operating system.
Application Recognition and Filtering is another useful feature.Â It lets us block traffic based onÂ port, IP address, protocol, and other characteristics.
We configure this by looking at our access points'Â logs and identifying the different types of traffic.Â We would then take that information andÂ decide if we want to block anything.
Let's go back up to the deviceÂ access policy and define a rule.Â We're going to create a rule thatÂ blocks traffic from video game consoles.Â We'll name the rule and add a description.Â Click Create New.
Notice, under OS/Type, that we have an option for gaming.Â This identifies traffic generated by videoÂ game consoles, such as an Xbox or PlayStation console.Â We want to deny this traffic, so we'llÂ select Deny from the rule type dropdown.Â Click Save > OK.
There's a number of other featuresÂ on this controller that you can use.Â We can add roles and policies that affectÂ users, and we can add users to the device.Â We can also configure the controller toÂ notify us of specific events via email.
On the Services page, we can configure self-healingÂ and background scanning, which are both very usefulÂ feature, but they're outside the scope of this video.Â We can also configure wireless intrusion detection.
Wireless intrusion detection and preventionÂ system (WIPS) is, actually, a very useful feature.Â It helps protect against wireless attacks such asÂ denial-of-service (DoS) attacks, rogue access points,Â evil twin attacks, and rogue DHCP servers.
For example, we can protect againstÂ repeated authentication attacks right here.Â We can even specify how long a client will be blocked.Â This helps protect our system from DoSÂ attacks and brute force attacks. We can also configure the controllerÂ to automatically flag APs trying to spoof anÂ SSID or MAC address as a malicious device.Â This is a great tool for protectingÂ against evil twin attacks.
That's it for this demonstration.Â In this demo, we discussed some of theÂ things you can do to harden a wirelessÂ network using a wireless network controller.

8.6.6 Harden a Wireless Network (Simulation)

Scenario

You are a network technician for a small corporate network. You need to increase the security of your wireless network. Your new wireless controller provides several security features that you want to implement.

Access the Wireless Controller console through Chrome on **http://192.168.0.6** with the username **admin** and the password **password** . The username and password are case-sensitive.

In this lab, your task is to:

Change the admin username and password for the Zone Director controller to the following:

Admin Name: **WxAdmin**

Password: **ZDAdminsOnly!$** (O is the capital letter O)

Set up MAC address filtering (L2 Access Control) to create an allow list called **Allowed Devices** that includes the following wireless devices:

00:18:DE:01:34:67

00:18:DE:22:55:99

00:02:2D:23:56:89

00:02:2D:44:66:88

Implement a device access policy called **NoGames** that blocks gaming consoles from the wireless network.

Explanation

Complete this lab as follows:

Access the Ruckus zone controller.

From the taskbar, select **Google Chrome** .

In the URL field, enter **192.168.0.6** and press **Enter** .

Maximize the window for better viewing.

Log in to the wireless controller console.

In the Admin field, enter **admin** (case sensitive).

In the Password field, enter **password** as the password.

Select **Login** .

Change the admin username and password for the Zone Director controller.

From the top, select the **Administer** tab.

Make sure **Authenticate using the admin name and password** is selected.

In the Admin Name field, enter **WxAdmin** .

In the Current Password field, enter **password** .

In the New Password field, enter **ZDAdminsOnly!$** .

In the Confirm New Password field, enter **ZDAdminsOnly!$** .

On the right, select **Apply** .

Enable MAC address filtering.

From the top, select the **Configure** tab.

From the left menu, select **Access Control** .

Expand **L2-L7 Access Control** .

Under *L2/MAC address Access Control* , select **Create New** .

In the Name field, enter **Allowed Devices** .

Under Restriction, make sure **Only allow all stations listed below** is selected.

Enter a ***MAC address*** .

Select **Create New** .

Repeat step 4g–4h for each MAC address you would like to add to the ACL.

Select **OK** .

Configure access controls.

Under Access Control, expand **Device Access Policy** .

Select **Create New** .

In the Name field, enter **NoGames** .

Select **Create New** .

In the Description field, enter **Games** .

Using the OS/Type drop-down list, select **Gaming** .

In the Type field, select **Deny** .

Under Uplink, make sure **Disabled** is selected.

Under Downlink, make sure **Disabled** is selected.

Select **Save** .

Select **OK** .

8.6.7 Configure WIPS (Simulation)

Scenario

You are a network technician for a small corporate network. You would like to enable Wireless Intrusion Prevention on the wireless controller. You are already logged in as WxAdmin.

Access the Wireless Controller console through Chrome on **http://192.168.0.6** .

In this lab, your task is to:

Configure the wireless controller to protect against denial-of-service (DOS) attacks as follows:

Protect against excessive wireless requests.

Block clients with repeated authentication failures for two minutes (120 seconds).

Configure Intrusion Detection and Prevention as follows:

Report all rogue devices regardless of type.

Protect the network from rogue access points.

Enable **Rogue DHCP Server Detection** .

Explanation

Complete this lab as follows:

Access the Ruckus zone controller.

From the taskbar, select **Google Chrome** .

In the URL field, enter **192.168.0.6** and press **Enter** .

Maximize the window for better viewing.

Configure Denial of Service protection.

Select the **Configure** tab.

From the left menu, select **WIPS** .

From the right, under *Denial of Services (DoS)* , select **Protect my wireless network against excessive wireless requests** .

Select **Temporarily block wireless clients with repeated authentication failures** .

Enter **120** seconds.

From the right of this section, select **Apply** .

Configure Intrusion Detection and Prevention:

Under *Intrusion Detection and Prevention* , select **Enable report rogue devices** .

Select **Report all rogue devices** .

Select **Protect the network from malicious rogue access points** .

From the right of this section, select **Apply** .

Configure Rogue DHCP Server Detection.

Under *Rogue DHCP Server Detection* , select **Enable rogue DHCP server detection** .

From the right of this section, select **Apply** .

8.6.8 Implement Secure Wireless Infrastructure

8.6.9 Practice Questions (Section Quiz)

q_wl_security_psk_secp8

You want to connect a laptop computer running Windows to a wireless network.

The wireless network uses multiple access points and WPA2-Personal. You want to use the strongest authentication and encryption possible. SSID broadcast has been disabled.

What should you do?

Answers:

***Configure the connection with a pre-shared key and AES encryption.**

Configure the connection to use 802.1x authentication and AES encryption.

Configure the connection with a pre-shared key and TKIP encryption.

Configure the connection to use 802.1x authentication and TKIP encryption.

Explanation:

To connect to a wireless network using WPA2-Personal, you need to use a pre-shared key for authentication. Advanced Encryption Standard (AES) encryption is supported by WPA2 and is the strongest encryption method.

WPA and WPA2 designations that include Personal or PSK use a pre-shared key for authentication.

Methods that include Enterprise use a RADIUS server for authentication and 802.1x authentication with usernames and passwords.

q_wl_security_update_firmware_secp8

A company's wireless network has been experiencing intermittent connectivity issues and slower than usual data transfer speeds.

The network administrator recently updated the firmware on the wireless access point (WAP) as part of a routine maintenance procedure. The update was applied during a scheduled downtime and the network was functional when the downtime ended.

However, the issues started appearing the next day. The administrator has checked the WAP settings and everything seems to be in order.

What could be the MOST likely cause of these issues?

Answers:

The WAP's firewall was accidentally disabled during the update.

***The network administrator failed to properly test new updates before pushing them out to the network.**

The MAC address filtering system was not configured correctly.

The Wi-Fi signal strength was set too high, causing interference.

Explanation:

The correct answer is most likely that the network administrator failed to properly test new updates before pushing them out to the network. Not properly testing new updates before pushing them out to the network could lead to unforeseen issues, such as the ones being experienced. The update could have introduced bugs or incompatibilities that were not apparent immediately after the update was applied.

The WAP's firewall being disabled could potentially allow unauthorized access to the network, but it would not typically cause intermittent connectivity issues or slower data transfer speeds.

Incorrect configuration of the MAC address filtering system could prevent certain devices from connecting to the network, but it would not typically cause intermittent connectivity or slower data transfer speeds for devices that are able to connect.

While a high Wi-Fi signal strength could potentially cause interference, it would not typically cause the specific issues being experienced unless there were other networks nearby on the same channel. Additionally, this would not explain why the issues started appearing after the firmware update.

q_wl_security_wpa2_01_secp8

Which of the following features is supplied by WPA2 on a wireless network?

Answers:

***Encryption**

Client-connection refusal based on MAC address

Traffic filtering based on packet characteristics

Network identification

Centralized access point for clients

Explanation:

Wi-Fi Protected Access (WPA) provides encryption and user authentication for wireless networks.

MAC address filtering allows or rejects client connections based on the hardware address.

The SSID is the network name or identifier.

A wireless access point (called an AP or WAP) is the central connection point for wireless clients.

A firewall allows or rejects packets based on packet characteristics (such as address, port, or protocol type).

q_wl_security_wpa2_02_secp8

You need to secure your wireless network.

Which security protocol would be the BEST choice?

Answers:

WEP

WPA

EFS

***WPA2**

802.11n

Explanation:

WEP, WPA, and WPA2 are all security protocols for wireless networks. Each security protocol protects the wireless data through the use of association keys and encryption protocols. However, WPA2 provides the best wireless security.

802.11n is a wireless standard with specific parameters for wireless data transmission.

The Encrypting File System (EFS) is a method for encrypting individual files within Windows.

q_wl_security_wpa2_03_secp8

You need to add security for your wireless network, and you would like to use the most secure method.

Which method should you implement?

Answers:

WEP

WPA

***WPA2**

Kerberos

Explanation:

Wi-Fi Protected Access 2 (WPA2) is currently the most secure wireless security specification. WPA2 includes specifications for both encryption and authentication.

WPA was an earlier implementation of security specified by the 802.11i committee. WEP was the original security method for wireless networks. WPA is more secure than WEP but less secure than WPA2.

Kerberos is an authentication method, not a wireless security method.

q_wl_auth_access_captive_secp8

The owner of a hotel has contracted with you to implement a wireless network to provide internet access for guests.

The owner has asked that you implement security controls so that only paying guests are allowed to use the wireless network. She wants guests to be presented with a login page when they initially connect to the wireless network. After entering a code provided by the concierge at check-in, guests should then be allowed full access to the internet. If a user does not provide the correct code, he or she should not be allowed to access the internet.

What should you do?

Answers:

***Implement a captive portal**

Implement MAC address filtering

Implement 802.1x authentication using a RADIUS server

Implement pre-shared key authentication

Explanation:

A captive portal would be the best choice in this scenario. A captive portal requires wireless network users to abide by certain conditions before they are allowed access to the wireless network. For example, the captive portal could require them to:

Agree to an acceptable use policy

Provide a PIN or password

Pay for access to the wireless network

View information or advertisements about the organization providing the wireless network (such as an airport or hotel)

When a wireless device initially connects to the wireless network, all traffic to or from that device is blocked until the user opens a browser and accesses the captive portal webpage. After the user provides the appropriate code, traffic is unblocked, and the host can access the network normally.

MAC address filtering and 802.1x authentication would work from a technical standpoint, but these would be completely unmanageable in a hotel scenario where guests come and go every day. Using a pre-shared key would require a degree of

technical expertise on the part of the hotel guests. It could also become problematic if the key were to be leaked, allowing non-guests to use the wireless network.

q_wl_auth_access_eap_802_01_secp8

An educational institution plans to upgrade its Wi-Fi network to improve security and control who can access the network while maintaining ease of connection for a large number of diverse users.

What is the BEST practice for this institution to improve its Wi-Fi network's security and manageability?

Answers:

***Implement the 802.1X standard using Extensible Authentication Protocol (EAP) for user authentication.**

Use a pre-shared key (PSK) for all devices.

Implement an open network and monitor network activity for unusual behavior.

Apply media access control (MAC) address filtering and maintain an authorized list of MAC addresses.

Explanation:

The network security administrator implements the 802.1X standard using EAP as best practice for enterprise Wi-Fi security. This allows for individual user authentication, which means the network provides access control at the user level.

The administrator might find using a PSK for all devices convenient, but it doesn't offer individual user accountability.

The administrator exposes the network to significant risk when they set up an open network and monitor activity. Unusual behavior is only detected after a security incident since any device can connect to the network.

The administrator applies MAC address filtering to prevent unauthorized devices from connecting, but managing this can be time-consuming with many users, and it is susceptible to MAC spoofing.

q_wl_auth_access_eap_802_02_secp8

A multinational corporation with numerous remote workers considers methods to enhance its network security. It wants to ensure that only authorized employees can connect their devices to the company network, regardless of location.

Which solution should the corporation implement to securely authenticate remote workers and maintain robust port security?

Answers:

***Employ 802.1X with Extensible Authentication Protocol (EAP) for robust port security and user authentication.**

Deploy a network that is open to all and regularly audit log files for suspicious activities.

Implement a media access control (MAC) address authorized list that only allows approved devices to connect to the network.

Use static Internal Protocol (IP) addresses for all employees and deny network access to devices with unrecognized IPs.

Explanation:

The network security administrator employs 802.1X with Extensible Authentication Protocol (EAP) for secure and robust user-level authentication. This works with a range of EAP methods depending on the corporation's specific needs and provides robust port security.

If the administrator sets up an open network and monitors and audits it for suspicious activities, it shows a lack of strong access control measures.

Maintaining a MAC address authorized list can be challenging for the administrator, especially in a multinational corporation with many employees. This approach also doesn't provide user-level access control.

The administrator finds using static IP addresses ineffective for remote workers who often need to have static IPs at their locations. This approach also doesn't provide any form of user authentication.

q_wl_auth_access_eap_radius_secp8

The security team at a multinational cloud services company is working on their port security. They implemented basic Media Access Control (MAC) address filtering on all switch ports, but they have concerns about the risk of MAC spoofing and the management overhead of maintaining a list of valid MAC addresses.

To address these concerns, they now require strong authentication before a user can obtain full network access.

Which of the following measures should the team implement next?

Answers:

***Implement EAP and RADIUS.**

Implement physical isolation for critical servers.

Disable all unused switch ports.

Segregate into multiple security zones.

Explanation:

Implementing IEEE 802.1X standard with extensible authentication protocol (EAP) and Remote Authentication Dial-In User Service (RADIUS) mitigates the risk of MAC spoofing and reduces management overhead of maintaining a list of valid MAC addresses. The switch requires authentication when a host connects to one of its ports, providing secure port access.

Physical isolation can provide strong security for critical servers, but it does not address the need for authenticated access at the port level.

While disabling unused ports can limit unauthorized physical access, it does not solve the problem of MAC spoofing or the overhead of maintaining MAC filtering.

Creating additional security zones can help limit the scope of potential network breaches but does not directly address port security.

q_wl_auth_access_eap_secp8

Which remote access authentication protocol allows for the use of smart cards for authentication?

Answers:

***EAP**

CHAP

PAP

PPP

SLIP

Explanation:

Extensible Authentication Protocol (EAP) is a set of interface standards that allows you to use various authentication methods, including smart cards, biometrics, and digital certificates.

Password Authentication Protocol (PAP) transmits login credentials in cleartext.

Challenge Handshake Authentication Protocol (CHAP) protects login credentials using a hash and allows for periodic re-authentication.

Point-to-Point Protocol (PPP) and Serial Line Interface Protocol (SLIP) are not remote access authentication protocols. They are used to establish the connection, not provide authentication.

q_wl_auth_access_eap_tls_01_secp8

Which EAP implementation is MOST secure?

Answers:

***EAP-TLS**

EAP-MD5

EAP-FAST

LEAP

Explanation:

EAP-TLS uses Transport Layer Security (TLS) and is considered one of the most secure EAP standards available. A compromised password is not enough to break into EAP-TLS enabled systems because the attacker must also have the client's private key.

EAP-MD5 offers minimal security and is susceptible to dictionary attacks and man-in-the-middle attacks. Lightweight Extensible Authentication Protocol (LEAP) does a poor job of protecting user authentication credentials and is also susceptible to dictionary attacks.

EAP-FAST is a replacement for LEAP that uses a protected access credential (PAC) to establish a TLS tunnel in which client authentication credentials are transmitted.

While more secure than EAP-MD5 and LEAP, EAP-FAST can still be compromised if the attacker intercepts the PAC.

q_wl_auth_access_eap_tls_02_secp8

The cybersecurity team at an international data center operator is enhancing its port security strategy. They have implemented rudimentary media access control (MAC) address filtering on all switch ports.

However, concerns about MAC spoofing and the administrative burden of maintaining a list of valid MAC addresses have surfaced. The team decided that robust authentication needs to occur before a user can gain comprehensive network access.

What strategy should the cybersecurity team adopt next?

Answers:

***Deploy EAP over TLS.**

Enforce physical isolation for servers.

Enable auxiliary switch ports.

Divide into secure segments.

Explanation:

Deploying the IEEE 802.1X standard with EAP over TLS effectively addresses concerns about MAC spoofing and the administrative overhead of maintaining a list of valid MAC addresses. It also switches mandates authentication when a host connects to one of its ports, providing secure port access.

Physical isolation provides robust security for backup servers but does not address the requirement for authenticated access at the port level.

Enabling auxiliary ports can open up more points for unauthorized access and does not address the problem of MAC spoofing or the overhead of maintaining MAC filtering.

Adding more secure segments can help limit the reach of potential network breaches but does not directly address port security.

q_wl_auth_access_mac_secp8

Which of the following do switches and wireless access points use to control access through a device?

Answers:

***MAC address filtering**

IP address filtering

Port number filtering

Session filtering

Explanation:

Both switches and wireless access points are Layer 2 devices, meaning they use the MAC address to make forwarding decisions. Both devices typically include some form of security that restricts access based on the MAC address.

Routers and firewalls operate at Layer 3 and can use the IP address or port number for filtering decisions.

A circuit-level gateway is a firewall that can make forwarding decisions based on the session information.

q_wl_auth_access_peap_01_secp8

The IT team of a large multinational corporation is working to improve the security of their remote access services. They plan to implement Remote Authentication Dial-In User Service (RADIUS) to enhance the authentication process for remote users. RADIUS provides a centralized authentication and authorization mechanism for users connecting from various locations.

The IT team evaluated different authentication protocols alongside RADIUS to ensure a strong and secure remote access solution.

Which choice of authentication protocols would be MOST appropriate to complement RADIUS for the company's remote access solution?

Answers:

***Protected Extensible Authentication Protocol (PEAP)**

Password Authentication Protocol (PAP)

Wired Equivalent Privacy (WEP)

Address Resolution Protocol (ARP)

Explanation:

Protected Extensible Authentication Protocol (PEAP) gets widely used with RADIUS for remote access authentication. It creates a secure transport layer security (TLS) tunnel for transmitting user credentials and provides a robust authentication method for remote users.

Password Authentication Protocol (PAP) is weak as it transmits passwords in plaintext, making it vulnerable to interception and unauthorized access.

Wired Equivalent Privacy (WEP) is an outdated and weak security protocol easily exploited, making it unsuitable for a secure remote access solution.

Address Resolution Protocol (ARP) is not an authentication protocol. ARP relates to mapping internet protocol (IP) addresses to media access control (MAC) addresses in local networks and is irrelevant to remote access security.

q_wl_auth_access_peap_02_secp8

The IT team of a medium-sized governmental agency took significant steps to bolster the security of their remote access services. Determined to fortify the authentication process for remote users, the team decided to implement Remote Authentication Dial-In User Service (RADIUS).

However, relying solely on RADIUS may not be enough to achieve their rock-solid remote access solution goal. To ensure the utmost protection, the team evaluated different authentication protocols that can complement and work seamlessly with RADIUS.

What authentication protocols should the team use to complement RADIUS for the company's remote access solution?

Answers:

***Protected Extensible Authentication Protocol (PEAP)**

Password Authentication Protocol (PAP)

Wired Equivalent Privacy (WEP)

Address Resolution Protocol (ARP)

Explanation:

Protected Extensible Authentication Protocol (PEAP) gets widely used with RADIUS for remote access authentication. It creates a secure transport layer security (TLS) tunnel for transmitting user credentials and provides a robust authentication method for remote users.

Password Authentication Protocol (PAP) is weak as it transmits passwords in plaintext, making it vulnerable to interception and unauthorized access.

Wired Equivalent Privacy (WEP) is an outdated and weak security protocol easily exploited, making it unsuitable for a secure remote access solution.

Address Resolution Protocol (ARP) is not an authentication protocol. ARP relates to mapping internet protocol (IP) addresses to media access control (MAC) addresses in local networks and is irrelevant to remote access security.

q_wl_auth_access_port_security_secp8

Which of the following methods can be used to ensure port security by completely disabling access to a network?

Answers:

Implementing IEEE 802.1X Port-based Network Access Control

Using a captive portal

***Physically removing the patch cable from the switch port**

MAC filtering

Explanation:

Physically removing the patch cable from the switch port is the correct answer. This is a method of port security where access to the physical switch ports and switch hardware is restricted to authorized staff. The switch port that the wall port cabling connects to can be administratively disabled, or the patch cable can be physically removed from the switch port. This method completely disables access to the network.

Implementing IEEE 802.1X Port-based Network Access Control is a method of port security where a switch requires authentication when a host connects to one of its ports. It uses authentication, authorization, and accounting (AAA) architecture to control access. However, this method does not completely disable access to the network.

Using a captive portal is a method used in open networks to force users to agree to terms and conditions or to pay a fee before being granted access. It does not disable access to the network, but rather controls it.

MAC filtering is a method of port security where a switch port only permits certain MAC addresses to connect. This can be done by creating a list of valid MAC addresses or by specifying a limit to the number of permitted addresses. However, this method does not completely disable access to the network.

q_wl_auth_access_radius_01_secp8

You want to implement 802.1x authentication on your wireless network.

Which of the following is required?

Answers:

WPA

WPA2

***RADIUS**

TKIP

Explanation:

802.1x authentication uses usernames and passwords, certificates, or devices such as smart cards to authenticate wireless clients. 802.1x authentication requires the following components:

- A RADIUS server to centralize user account and authentication information. A centralized database for user authentication is required to allow wireless clients to roam between cells but authenticate using the same account information.
- A public key infrastructure (PKI) for issuing certificates. At a minimum, the RADIUS server must have a server certificate. To support mutual authentication, each client must also have a certificate.

You can use 802.1x authentication with both WPA and WPA2 and even with WEP on some devices and operating systems. Temporary Key Integrity Protocol (TKIP) is an encryption method used with WPA.

q_wl_auth_access_radius_02_secp8

You want to implement 802.1x authentication on your wireless network.

Where would you configure passwords that are used for authentication?

Answers:

***On a RADIUS server**

On the wireless access point

On the wireless access point and on each wireless device

On a certificate authority (CA)

Explanation:

802.1x authentication uses usernames and passwords, certificates, or devices such as smart cards to authenticate wireless clients. Authentication requests received by the wireless access point are passed to a RADIUS server, which validates the login credentials (such as the username and password).

If you are using pre-shared keys for authentication, configure the same key on the wireless access point and on each wireless device.

A CA is required to issue a certificate to the RADIUS server.

The certificate proves the identity of the RADIUS server and can also be used to issue certificates to individual clients.

q_wl_auth_access_radius_03_secp8

You are the wireless network administrator for your organization. As the size of the organization has grown, you've decide to upgrade your wireless network to use 802.1x authentication instead of pre-shared keys.

To do this, you need to configure a RADIUS server and RADIUS clients. You want the server and the clients to mutually authenticate with each other.

What should you do? (Select two. Each response is a part of the complete solution.)

Answers:

***Configure the RADIUS server with a server certificate.**

***Configure all wireless access points with client certificates.**

Configure all RADIUS clients with a pre-shared key.

Configure the RADIUS server with a pre-shared key.

Configure all wireless workstations with client certificates.

Explanation:

When you use 802.1x authentication for wireless networks, a RADIUS server is implemented to centralize authentication. A centralized authentication database is used to allow wireless clients to roam between cells but authenticate using the same account information. To authenticate devices, PKI is required to issue certificates. At a minimum, the RADIUS server must have a server certificate. However, to support mutual authentication, each RADIUS client must also have a certificate. Remember that in a RADIUS solution, each wireless access point is a RADIUS client, not the wireless devices. The wireless access points forward the credentials from wireless devices to the RADIUS server for authentication.

Pre-shared keys are not used for authentication in an 802.1x solution.

q_wl_auth_access_radius_04_secp8

You are replacing a wired business network with an 802.11g wireless network. You currently use Active Directory on the company network as your directory service. The new wireless network has multiple wireless access points, and you want to use WPA2 on the network.

What should you do to configure the wireless network? (Select two.)

Answers:

***Install a RADIUS server and use 802.1x authentication**

***Configure devices to run in infrastructure mode**

Configure devices to run in ad hoc mode

Use open authentication with MAC address filtering

Use shared secret authentication

Explanation:

When using wireless access points, configure an infrastructure network. Because you have multiple access points and an existing directory service, you can centralize authentication by installing a RADIUS server and using 802.1x authentication.

Use ad hoc mode when you need to configure a wireless connection between two hosts.

Use open authentication with WEP or when you do not want to control access to the wireless network.

Use shared secret authentication with WPA or WPA2 when you can't use 802.1x.

q_wl_auth_access_security_secp8

You've just finished installing a wireless access point for a client.

What should you do to prevent unauthorized users from using the access point (AP) configuration utility?

Answers:

***Change the administrative password on the AP.**

Isolate the AP from the client's wired network.

Change the channel used by the AP's radio signal.

Implement MAC address filtering.

Explanation:

You should change the administrative password used by the AP. Many AP manufacturers use a default administrative username and password that are well known. If you don't change these parameters, anyone connecting to the AP can easily guess the password required to access the AP's configuration.

A wired and wireless network are already isolated from each other.

Changing the channel will not prevent unauthorized users from finding the channel and prevent them from accessing the available Wi-Fi.

MAC address filtering allows you to block traffic coming from certain known machines or devices. However, in this scenario, you are attempting to block unauthorized incoming traffic.

q_wl_auth_access_wpa2_secp8

You need to configure a wireless network using WPA2-Enterprise.

Which of the following components should be part of your design? (Select two.)

Answers:

TKIP encryption

***AES encryption**

WEP encryption

***802.1x**

Open authentication

Pre-shared keys

Explanation:

To configure WPA2-Enterprise, you need a RADIUS server to support 802.1x authentication. WPA2 uses AES for encryption.

WPA2-PSK, also called WPA2-Personal, uses pre-shared keys for authentication. WPA uses TKIP for encryption.

Using open authentication, any wireless device can authenticate with the access point, but the device can communicate only if its Wired Equivalent Privacy (WEP) keys match the access point's WEP keys. In this scenario, you are using WPA (not WEP) for authentication.

8.7 Data Transmission Security

As you study this section, answer the following questions:

How does SSL verify authentication credentials?

What protocol is the successor to SSL 3.0?

How can you tell that a session with a web server is using SSL?

What is the difference between HTTPS and S-HTTP?

What does it mean when HTTPS is stateful?

What is the difference between IPsec tunnel mode and transport mode?

In this section, you will learn to:

Add TLS to a website

Allow SSL connections

Require IPsec for communications

The key terms for this section include:

Term	Definition
Secure Sockets Layer (SSL)	A protocol that secures messages being transmitted on the internet.
Transport Layer Security (TLS)	A protocol that secures messages being transmitted on the internet. It is the successor to SSL 3.0.
Secure Shell (SSH)	A protocol that allows for secure interactive control of remote systems.
Hyper Text Transfer Protocol Secure (HTTPS)	A secure form of HTTP that uses either SSL or TLS to encrypt sensitive data before it is transmitted.
Secure Hypertext Transfer Protocol (S-HTTP)	An alternate protocol that is not widely used because it is not as secure as HTTPS.
Internet Protocol Security (IPsec)	A set of protocols that provides secure data transmission over unprotected TCP/IP networks.
Authentication Header (AH)	A protocol within IPsec that provides authenticity, non-repudiation, and integrity.
Encapsulating Security Payload (ESP)	A protocol within IPsec that provides all the security of AH plus confidentiality.
Security Association (SA)	The establishment of shared security information between two network entities to support secure communications.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	1.4 Explain the importance of using appropriate cryptographic solutions. Encryption Transport/communication Asymmetric Key exchange Certificates Certificate authorities 2.4 Given a scenario, analyze indicators of malicious activity. Network attacks Domain Name System (DNS) attacks 3.2 Given a scenario, apply security principles to secure enterprise infrastructure. Secure communication/access Virtual private network (VPN) Remote access Tunneling Transport Layer Security (TLS) Internet Protocol Security (IPSec)
TestOut Security Pro	3.2 Implement application defenses 3.2.3 Configure web application security 4.2 Implement Encryption Technologies 4.2.1 Encrypt data communications

8.7.1 Secure Protocols (Lesson Video)

Transcript:

FILE NOT FOUND

8.7.2 Secure Protocol Facts

Many protocols created in the past were designed with few to no security controls. An unsecured protocol is one that does not provide authentication or encryption or one that uses plaintext for passing authentication information or data. Newer protocols with security controls include Secure Sockets Layer (SSL), Transport Layer Security (TLS), Secure Shell (SSH), HyperText Transfer Protocol (HTTP), and HyperText Transfer Protocol Secure (HTTPS).

This lesson covers the following topics:

- Remote desktop
- Secure Shell
- HTTPS and S-HTTP

Remote Desktop

A remote access VPN joins the user's PC or smartphone to a remote private network via a secure tunnel over a public network. Remote access can also be a means of connecting to a specific computer over a network. This type of remote access involves connecting to a terminal server on a host using software that transfers shell data only. The connection could be a client and terminal server on the same local network or across remote networks.

A graphical remote access tool sends screen and audio data from the remote host to the client and transfers mouse and keyboard input from the client to the remote host. Microsoft's Remote Desktop Protocol (RDP) can be used to access a physical machine on a one-to-one basis.

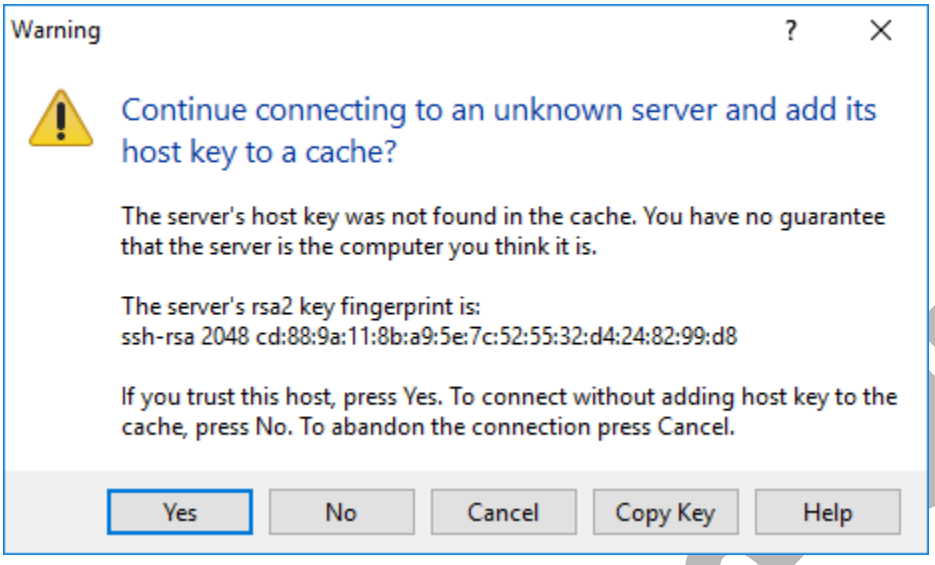
Alternatively, a site can operate a remote desktop gateway that facilitates access to virtual desktops or individual apps running on the network servers. RDP connections are encrypted by default. There are several popular alternatives to Remote Desktops. Most support remote access to platforms other than Windows (macOS and iOS, Linux, Chrome OS, and Android, for instance). Examples include TeamViewer (teamviewer.com/en) and Virtual Network Computing (VNC) , which is implemented by several different providers (notably realvnc.com/en).

In the past, these remote desktop products required a dedicated client app. Remote desktop access can now just use a web browser client. The canvas element introduced in HTML5 allows a browser to draw and update a desktop with relatively little lag. It can also handle audio. This is referred to as an HTML5 VPN or as a clientless remote desktop gateway (guacamole.apache.org). This solution uses a protocol called WebSocket, which enables bidirectional messages to be sent between the server and client without requiring the overhead of separate HTTP requests.

Secure Shell

Secure Shell (SSH) is the principal means of obtaining secure remote access to a command line terminal. The main uses of SSH are for remote administration and secure file transfer (SFTP). Numerous commercial and open - source SSH products are available for all the major NOS platforms. The most widely used is OpenSSH (openssh.com).

SSH servers are identified by a public/private key pair that is referred to as the Host Key. Hostnames can be mapped to Host Keys manually by each SSH client or through various enterprise software products designed for SSH Host Key management.



Confirming the SSH server's Host Key using the PuTTY SSH client (Screenshot used with permission from PuTTY.)

The Host Key must be changed if any compromise of the host is suspected. If an attacker has obtained the private key of a server or appliance, they can masquerade as that server or appliance and perform a spoofing attack, usually with a view to obtaining other network credentials.

The server's Host Key is used to set up a secure channel for the client to submit authentication credentials.

Type	Description
SSH client authentication	SSH allows various methods for the client to authenticate to the server. Each of these methods can be enabled or disabled as required on the server using the /etc/ssh/sshd_config file: **Username/password** - is when the client submits credentials verified by the SSH server either against a local user database or using a RADIUS server. **Public key authentication** - is when each remote user's public key is added to a list of keys authorized for each local account on the SSH server. **Kerberos** - is when the client submits the Kerberos credentials (a Ticket Granting Ticket) obtained when the user logs onto the workstation to the server using the Generic Security Services Application Program Interface (GSSAPI). The SSH server contacts the Ticket Granting Service (in a Windows environment, this will be a domain controller) to validate the credentials. Managing valid client public keys is a critical security task. Many recent attacks on web servers have exploited poor key management. If a user's private key is compromised, delete the public key from the appliance, regenerate the key pair on the user's (remediated) client device, and copy the public key to the SSH server. Always delete public keys when the user's access permissions have been revoked.

SSH commands	SSH commands are used to connect to hosts and set up authentication methods. To connect to an SSH server at 10.1.0.10 using an account named "bobby" and password authentication, run: ssh bobby@10.1.0.10 The following commands create a new key pair and copy it to an account on the remote server: ssh-keygen -t rsa ssh-copy-id bobby@10.1.0.10 At an SSH prompt, you can now use the standard Linux shell commands. Use exit to close the connection. You can use the scp command to copy a file from the remote server to the local host: scp bobby@10.1.0.10:/logs/audit.log audit.log Reverse the arguments to copy a file from the local host to the remote server. To copy the contents of a directory and any subdirectories (recursively), use the -r option.

HTTPS and S-HTTP

A common unsecured protocol is the HyperText Transfer Protocol (HTTP). HTTP is used for exchanging web content and passes data in cleartext. HTTP uses TCP port 80 and is stateless, which means, by default, it does not keep track of clients. To solve this problem, cookies can be used to keep track of the client's behavior. To secure HTTP, use one of the following protocols:

Protocol	Description
HTTPS	HyperText Transfer Protocol Secure is a secure form of HTTP that uses SSL or TLS to encrypt sensitive data before it is transmitted. HTTPS: Is stateful, which means that it keeps track of the client. To do this, the client must communicate with the same HTTPS server for the duration of the session. Load balancing is not possible during the connection and is available only to initially determine which server will handle the client's session. Requires TCP port 443 inbound on the webserver to be open. Can be identified by verifying that the URL starts with https:// or by looking for a lock symbol in the browser. Double-clicking on the lock icon displays the certificate.
S-HTTP	Secure HyperText Transfer Protocol (S-HTTP) is an alternate protocol that is not widely used because it is not as secure as HTTPS. S-HTTP: Is connectionless, unlike SSL, which is connection-oriented.

	Provides only message security, unlike HTTPS, which provides a full secure channel for all messages. Does not use port 443.

8.7.3 Add TLS to a Website (Demo Video)

Transcript:

In this demonstration, we'll look at using SSL for a website. We're going to use Windows Server 2022 to configure a website. We're on this client machine in Windows 11 with a browser open.

As you can see, we're using HTTP for this website, so traffic sent between the client and the website is unsecured. To secure communication between the client and the website, we can add SSL to the website. We do this by editing the bindings. The bindings identify the protocols that are used on the website. Currently, we support the HTTP protocol, which uses port 80. To use SSL, we need to add bindings for HTTPS.

Before we get into this demo, we need to talk about the terminology used for SSL and TLS. For the last few years, there's been a large push in the IT industry to deprecate TLS versions 1.0 and 1.1 and require all encrypted internet traffic to use TLS version 1.2 or later. SSL is the predecessor to TLS. The last version of SSL, version 3.0, was found to be insecure. SSL 3.0 was deprecated in 2015 by the IETF in RFC 7568.

If SSL was deprecated in 2015, why do we still see the SSL acronym everywhere? You still see websites selling SSL certificates, and many of Microsoft's own tools still reference SSL certificates—including tools you'll see in this demo. The answer is that because the SSL term was so prevalent at the time it was deprecated, people are still adjusting to using TLS. When you hear someone talk about or see documentation referencing SSL, they are usually talking about TLS. The SSL protocol hasn't been used on the internet for years and isn't supported in modern web browsers. Up-to-date versions of Chrome, Edge, and Firefox require TLS connections for encryption and won't allow you to connect to a web server that's trying to use SSL.

Please make a note of this as we go through this demo and as you get into your IT career. While the term SSL is still commonly used in both speech and documentation, the protocol SSL has been fully replaced by TLS for many years.

We're going to go to the Internet Information Service Manager, so let's switch over to our server. Let's go to Start and Server Manager. In the tools, we'll select IIS Manager. First, we're going to go down to our default website. We can right-click the Default Web Site we've created. Go to edit Bindings. We can see our HTTP port 80 here. We'll click Add.

We can switch this to HTTPS. You can see that it automatically switches to port 443. Notice that secure communications with this website use port 443 instead of port 80. When using SSL, you must also have a server certificate, or SSL certificate. The certificate identifies the server and validates its identity. In this case, we don't currently have a certificate set up, so we're going to click Cancel and Close. We'll go to our server and go to Server Certificates.

Now, if our website were available on the internet, we'd create a certificate request here and send that request to a well-known public key infrastructure, or PKI, such as DigiCert. When that request was returned, we'd use this complete certificate request option to import the completed certificate onto our server. In this demonstration, we're going to use Create Self-Signed Certificate. The self-signed certificate gives us a certificate that we can use. However, clients won't automatically trust the certificate that we use. We'll see how this works later. We'll enter a name for the certificate. And we'll call it Cert 2022 and click OK.

You can see our certificate here. With this certificate created, we'll go back to our Default Web Site, right-click, Edit Bindings > Add > HTTPS. It switches to the 443. HTTP/2 is how semantics flow over TCP connections. Most browsers support HTTP/2, so disabling this may not be needed. OCSP Stapling checks to see if a certificate is revoked and has been an alternative to the Certificate Revocation List (CRL) Protocol. We'll leave both of those unchecked for now. We're going to go down, and we can see our Cert 2022 right here. Select it and click OK and Close.

That certificate's created. Now, we can go over to our client machine and test this out. We're back on our Windows 11 client machine. We need to put https:// in front of the address and hit enter. The first message we get is that there's a problem with the website's security certificate. We started to use HTTPS, but our computer recognized that the certificate wasn't issued by a trusted certificate authority. In other words, the server has no proof, other than its own words, to verify its identity.

In this case, we know who the server is, so we can continue to the website and accept the certificate. Notice that we're accessing the website. The URL is HTTPS. Let's go ahead and click Continue. The message told us there was a problem with the certificate, but we're still using HTTPS to connect to the website. In this case, we're giving the user the option of using HTTPS or HTTP when communicating with our server. A more likely example is to require SSL for certain communications.
In this case, we're going to require SSL for the entire website, so a connection won't be granted unless the client and the server are both using SSL. To do this, we're going to go back to our web server, to Internet Information Services Manager.
We're going to click the Default Web Site. Go to SSL Settings. We're going to tell it to Require SSL. We'll check the box and hit Apply to save those changes. Now, we can go back to the client.
First, let's try to access the website using just HTTP. We'll just go ahead and take out the S. That's all we have to do. Hit Enter. We get this error that says access is denied. Now, let's go ahead and put the S back. It's basically denying us unless we're using an SSL certificate with a secure connection. You can see it went ahead and let us back in. The website requires SSL.
We were trying to use HTTP, but it won't let us. Now that we're using HTTPS, we can access the website because the client and the server are both using SSL. In this example, we've required SSL on the entire website, meaning that any communication to the website must use SSL or be denied. It's unlikely that you may require SSL only for specific parts of the website.
Today, it's recommended always to use HTTPS with a public-facing website, regardless of whether it's a basic website or one used for credit card purchases. By only using HTTP, hackers have easy access to view traffic in plain text.
That's it for this demo. We've gone over how to configure SSL on a website using Windows Server 2022. We've also clarified that SSL as a protocol is no longer used and has been fully replaced by TLS, even though the term SSL is still widely used in common speech and documentation.

8.7.4 Allow SSL Connections (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You currently run a website on the CorpWeb server. You want to allow SSL connections to this website.

In this lab, your task is to add a binding to the CorpNet website using the following settings:

Website: **www.corpnet.xyz**

Protocol: **HTTPS**

Port: **443**

SSL certificate: **www.corpnet.xyz**

Explanation

Complete this lab as follows:

Open the IIS Manager to the CorpNet.xyz site.

From the Server Manager's menu bar, select **Tools** > **Internet Information Services (IIS) Manager** .

Expand **CorpWeb (CorpNet.com\Administrator)** > **Sites** .

Select **CorpNet.xyz** .

Add a binding to the CorpNet website.

From the Actions pane (far right), select **Bindings** .

Select **Add** .

Using the *Type* drop-down menu, select **HTTPS** .

Make sure the port is set to **443** .

Using the *SSL certificate* drop-down menu, select **www.CorpNet.xyz** and then select **OK** .

Select **Close** .

8.7.5 IPsec (Lesson Video)

Transcript:

In this lesson, we'll cover Internet Protocol Security, or Ipsec, which is a set of security protocols used to provide authentication and asymmetric encryption for TCP/IP network traffic. It's also used in VPNs.

IPsec operates on top of the Network layer, or Layer 3, of the OSI model. The OSI model provides standards for communication in a computing system, which allows interoperability of various systems regardless of their internal structures. It's composed of seven layers, each layer being served by the layer below it. The bottom three layers are the media layers, and the top four layers are the host layers. Layer 3's primary goal is communication, not security. Applying IPsec on top of Layer 3 provides security to the communication through mutual authentication, integrity, non-repudiation, and confidentiality.
The first protocol in the IPsec suite is called Authentication Header, or AH. It encapsulates all the Host layer information, which includes Layers 4 through 7, and replaces it with an authentication header. AH will detect if the IP address on Layer 3 changes through a checksum for all the data from Layers 3 through 7. This provides authenticity and integrity, but not confidentiality because the encapsulated data in the packet is not encrypted. If the packet were intercepted by a sniffer, the data could be read.
AH provides authentication information in the form of a keyed hash, which is based on all the bytes in the packet. AH authenticates packets by digitally signing them, which prevents replay attacks. AH's assigned IP protocol number is 51.
The second IPsec protocol option is Encapsulating Security Protocol, or ESP. It's commonly used with IPsec because it provides everything that AH provides plus confidentiality. ESP's assigned IP protocol number is 50.
Like AH, ESP encapsulates the Host layers, 4 through 7, into a new Layer 4 header called an ESP header. Unlike AH, it encrypts the encapsulated data, preventing someone from reading the data if it's sniffed. Also unlike AH, ESP doesn't notice when a lower level IP address changes because there isn't a checksum that includes Layer 3 information. To solve this problem, ESP works best with Network Address Translation, or NAT.
An important consideration is that NAT can have problems with IPsec. Problems can come because IPsec secures the headers of packets and detects if the packets have been tampered with, and NAT needs to tamper with packets by changing source and destination IP addresses and ports.
To fix this, something called NAT Traversal, or NAT-T, was created. NAT-T is designed to allow IPsec to function properly through a NAT device. It does this by encapsulating ESP packets inside a UDP packet and uses UDP port 4500.
Another part of IPsec to consider is the set of specifications that negotiate between nodes to establish the IPsec relationship called a Security Association, or SA. These specifications can include cryptographic keys, authentication preferences, certificates, and algorithm selections.
For example, both endpoints can agree to use the SHA-1 hashing algorithm instead of MD5, AES for symmetric encryption, and RSA for asymmetric encryption. Each tunnel of data uses three different security associations.
First, a management channel is established so that routers or network nodes can exchange security information. Then an outbound security association and an inbound security association are established, each with a unique identifier that's

included with each packet sent across the channel. A security association can be established manually or automatically through a protocol called IKE, Internet Key Exchange.
IKE helps establish automatic SAs and a secure tunnel by providing a protected exchange of keys before the full IPsec transmission begins. IKE uses a Diffie-Hellman key exchange to establish a shared session secret. Mutual authentication is provided either by pre-shared keys on both endpoints or through certificates issued by a CA. IKE can also help automate the selection of the best security association for each connection.
For example, if both endpoints support Triple DES and AES for symmetric encryption, then IKE can help them negotiate the strongest security method, AES. Once that's agreed on, they're placed into their SAs. Now their symmetric encryption algorithm is set to encrypt and decrypt data with the IPsec tunnel.
Finally, there are two modes that are available to use with IPsec circuits, including VPNs.
The first is called tunnel mode. It's commonly used to provide secure communication between two network gateways. For example, it will allow any user at Corporate Office A to communicate safely with any user at Corporate Office B because both offices have secure gateways acting as IPsec proxies.
The second is called transport mode. It's used when two hosts connect directly with each other and the circuit is broken off after the session ends.
That's it for this lesson. In this lesson, we discussed how IPsec secures IP traffic across the network. Then we looked at elements of the IPsec suite. First, we looked at AHs, or Authentication Headers. Then we looked at ESP, or Encapsulating Security Payload. Remember to use NAT-T to enable ESP to function properly. Next, we discussed how Security Association specifications work. Then we looked at using Internet Key Exchange protocol to implement the SAs. Finally, we covered the two IPsec modes, tunnel mode and transport mode. Tunnel mode allows protected communication between users at both ends of the secure tunnel through their gateways, and transport mode is for direct connection between hosts for a specific session.

8.7.6 IPsec Facts

This lesson covers the following topics:

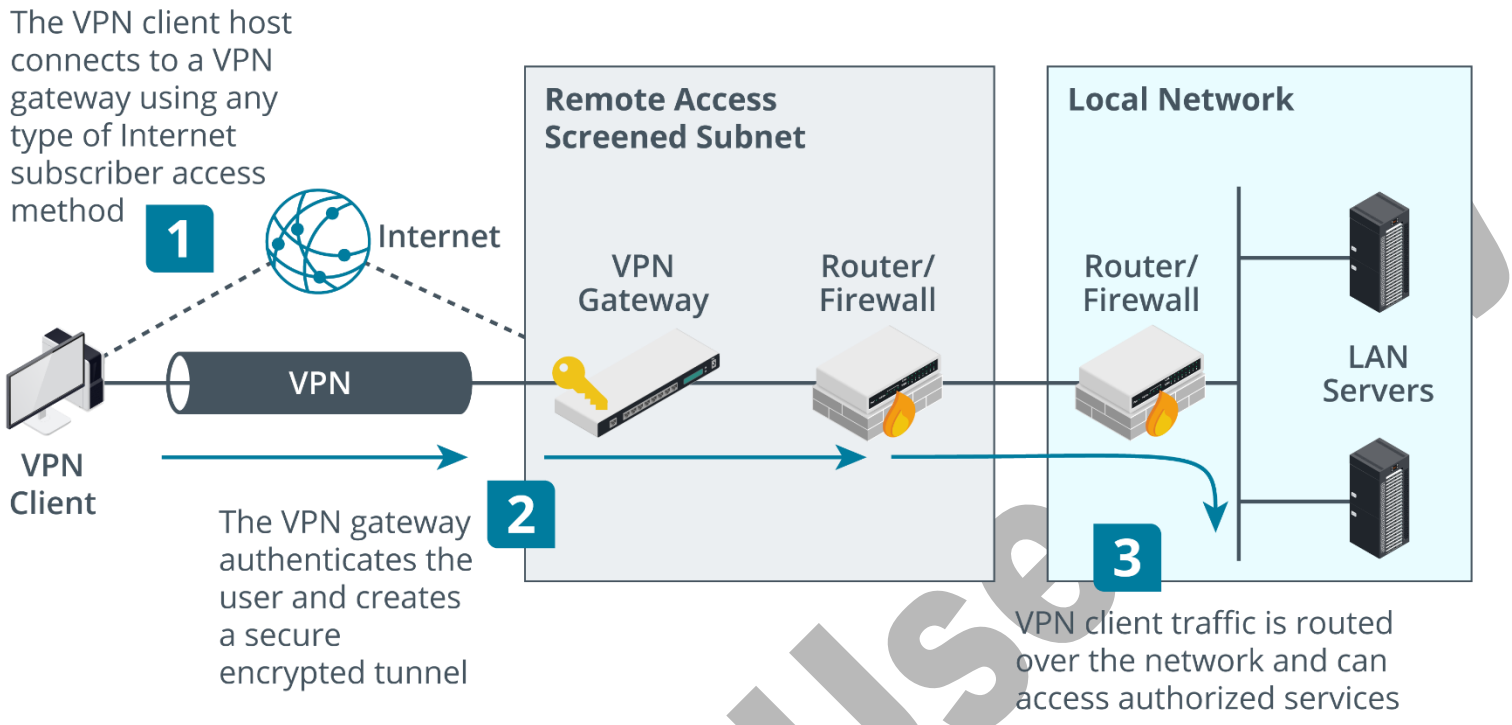
- Remote access architecture
- Internet Protocol Security tunneling
- Transport layer security tunneling

Remote Access Architecture

Remote access networking means that the user's device does not make a direct cable or wireless connection to the network. The connection occurs over or through an intermediate network.

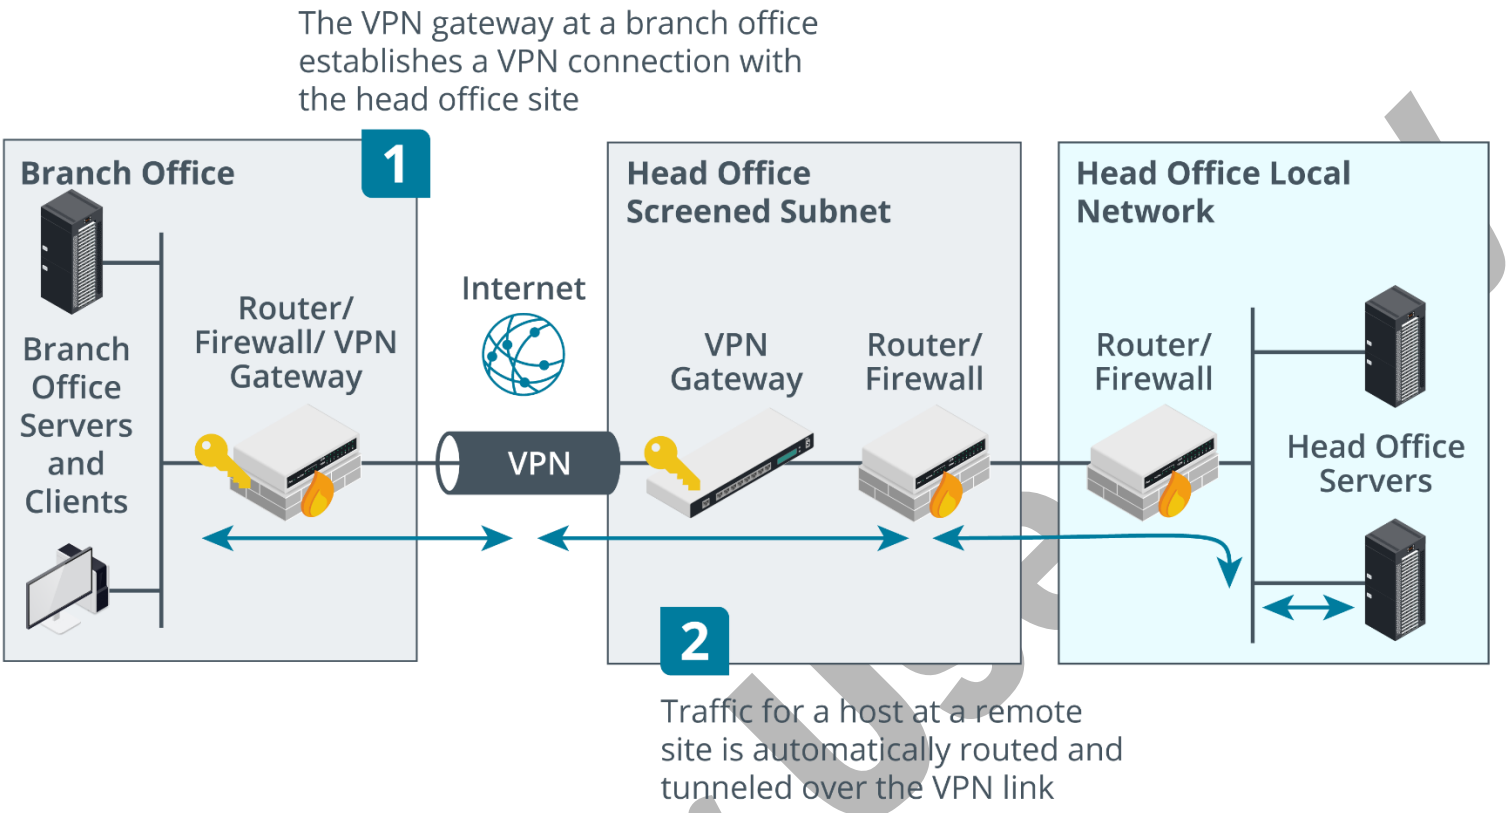
Historically, remote access used analog modems connecting over the telephone system. These days, most remote access is implemented as a virtual private network (VPN) , running over Internet Service Provider (ISP) networks.

With a remote access VPN, clients connect to a VPN gateway on the edge of the private network. This client-to-site VPN topology is the "telecommuter" model, allowing homeworkers and employees working in the field to connect to the corporate network. The VPN protocol establishes a secure tunnel to keep the contents private, even when the packets pass over ISPs' routers.



Remote access VPN. (Images © 123RF.com.)

A VPN can also be deployed in a site-to-site model to connect two or more private networks. Whereas remote access VPN connections are typically initiated by the client, a site-to-site VPN is configured to operate automatically. The gateways exchange security information using whichever protocol the VPN is based on. This establishes a trust relationship between the gateways and sets up a secure connection through which to tunnel data. Hosts at each site do not need to be configured with any information about the VPN. The routing infrastructure at each site determines whether to deliver traffic locally or send it over the VPN tunnel.



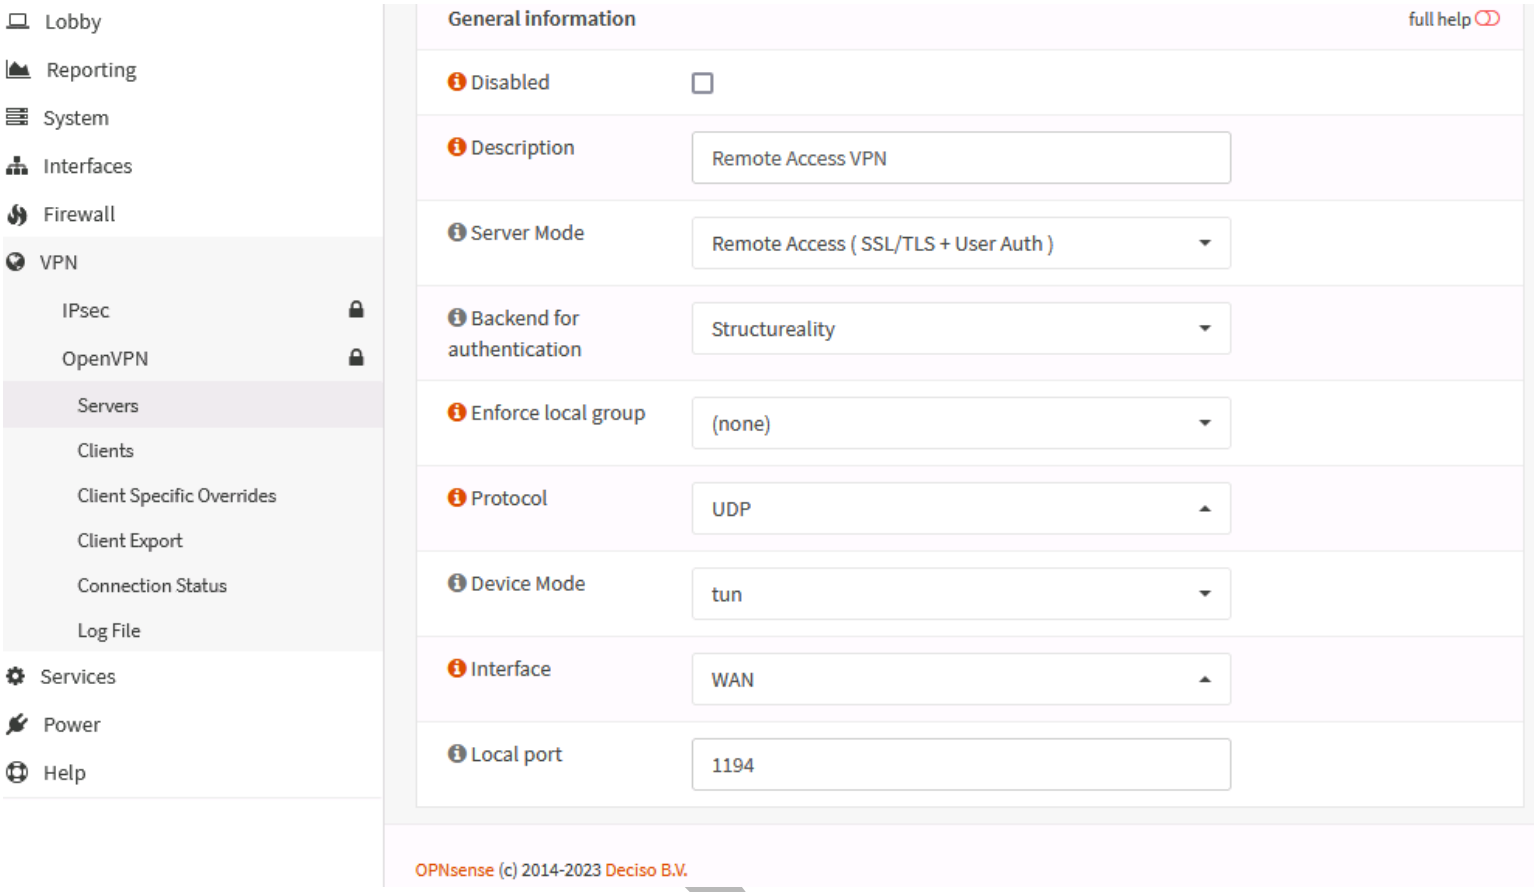
Site-to-site VPN. (Images © 123RF.com.)

A third topology is a **host-to-host tunnel** . This is a means of securing traffic between two computers where the private network is not trusted.

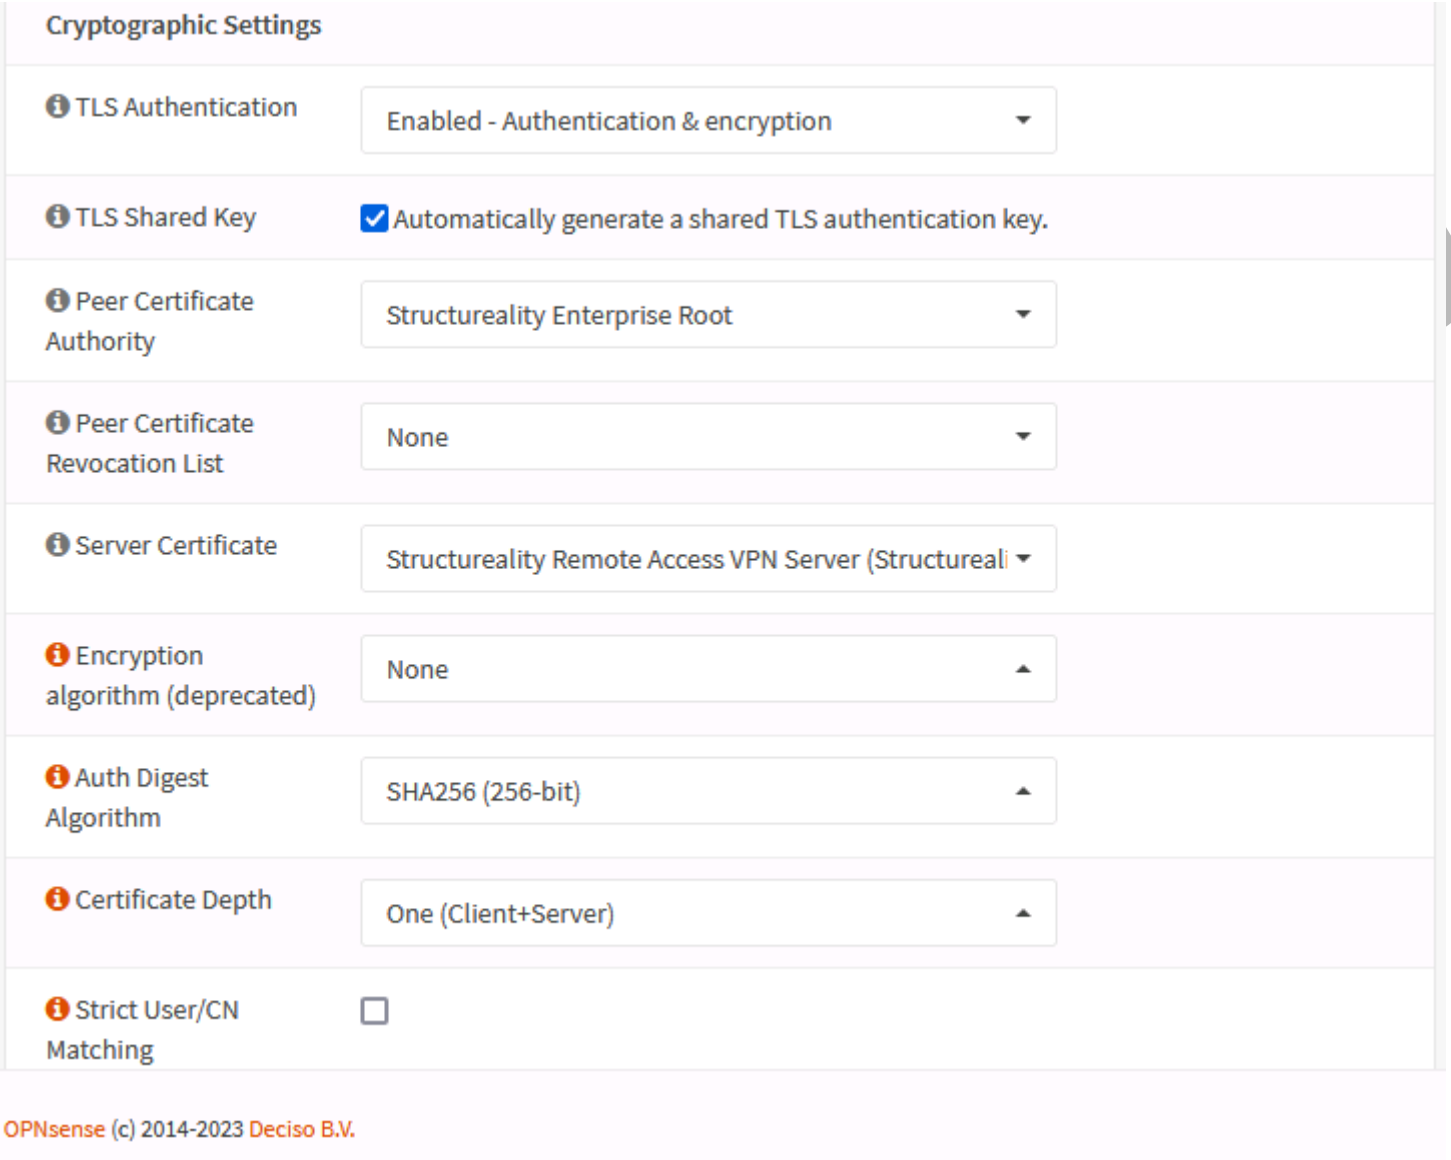
Several VPN protocols have been used over the years. Legacy protocols, such as the Point-to-Point Tunneling Protocol (PPTP) , have been deprecated because they do not offer adequate security. Transport Layer Security (TLS) and Internet Protocol Security (IPsec) are now the preferred options for configuring VPN access.

Transport Layer Security Tunneling

A transport layer security (TLS) VPN means the client connects to the remote access server using digital certificates. The server certificate identifies the VPN gateway to the client. Optionally, the client can also be configured with its own certificate. This allows for mutual authentication, where both server and client prove their identity to one another. TLS creates an encrypted tunnel for the user to submit authentication credentials. These would normally be processed by a RADIUS server. Once the user is authenticated and the connection is fully established, the VPN gateway tunnels all communications for the local network over the secure socket.



Configuring an OpenVPN server in the OPNsense security appliance. This configuration creates a remote access VPN. Users are authenticated via a RADIUS server on the local network. (Screenshot courtesy of OPNsense.)



Configuring a server certificate for OpenVPN in the OPNsense security appliance. (Screenshot courtesy of OPNsense.)

A TLS VPN can use either TCP or UDP. UDP might be chosen for marginally superior performance, especially when tunneling latency-sensitive traffic such as voice or video. TCP might be easier to use with a default firewall policy. TLS over UDP is also referred to as Datagram TLS (DTLS).

It is important to use a secure version of TLS. The latest version at the time of writing is TLS 1.3. TLS 1.2 is also still supported. Versions earlier than this are deprecated.

Internet Protocol Security Tunneling

Transport Layer Security is applied at the application level. Internet Protocol Security (IPsec) operates at the network layer of the OSI model (layer 3). This means that it can be implemented without having to configure specific application support and that it incurs less packet overhead.

There are two core protocols in IPsec, which can be applied singly or together, depending on the policy:

Authentication Header (AH) - performs a cryptographic hash on the whole packet, including the IP header, plus a shared secret key (known only to the communicating hosts), and adds this value in its header as an Integrity Check Value (ICV). The recipient performs the same function on the packet and key and should derive the same value to confirm that the packet has not been modified. The payload is not encrypted, so this protocol does not provide confidentiality.

Encapsulating Security Payload (ESP) can be used to encrypt the packet rather than simply calculating an ICV. ESP attaches three fields to the packet: a header, a trailer (providing padding for the cryptographic function), and an Integrity Check Value. Unlike AH, ESP excludes the IP header when calculating the ICV.

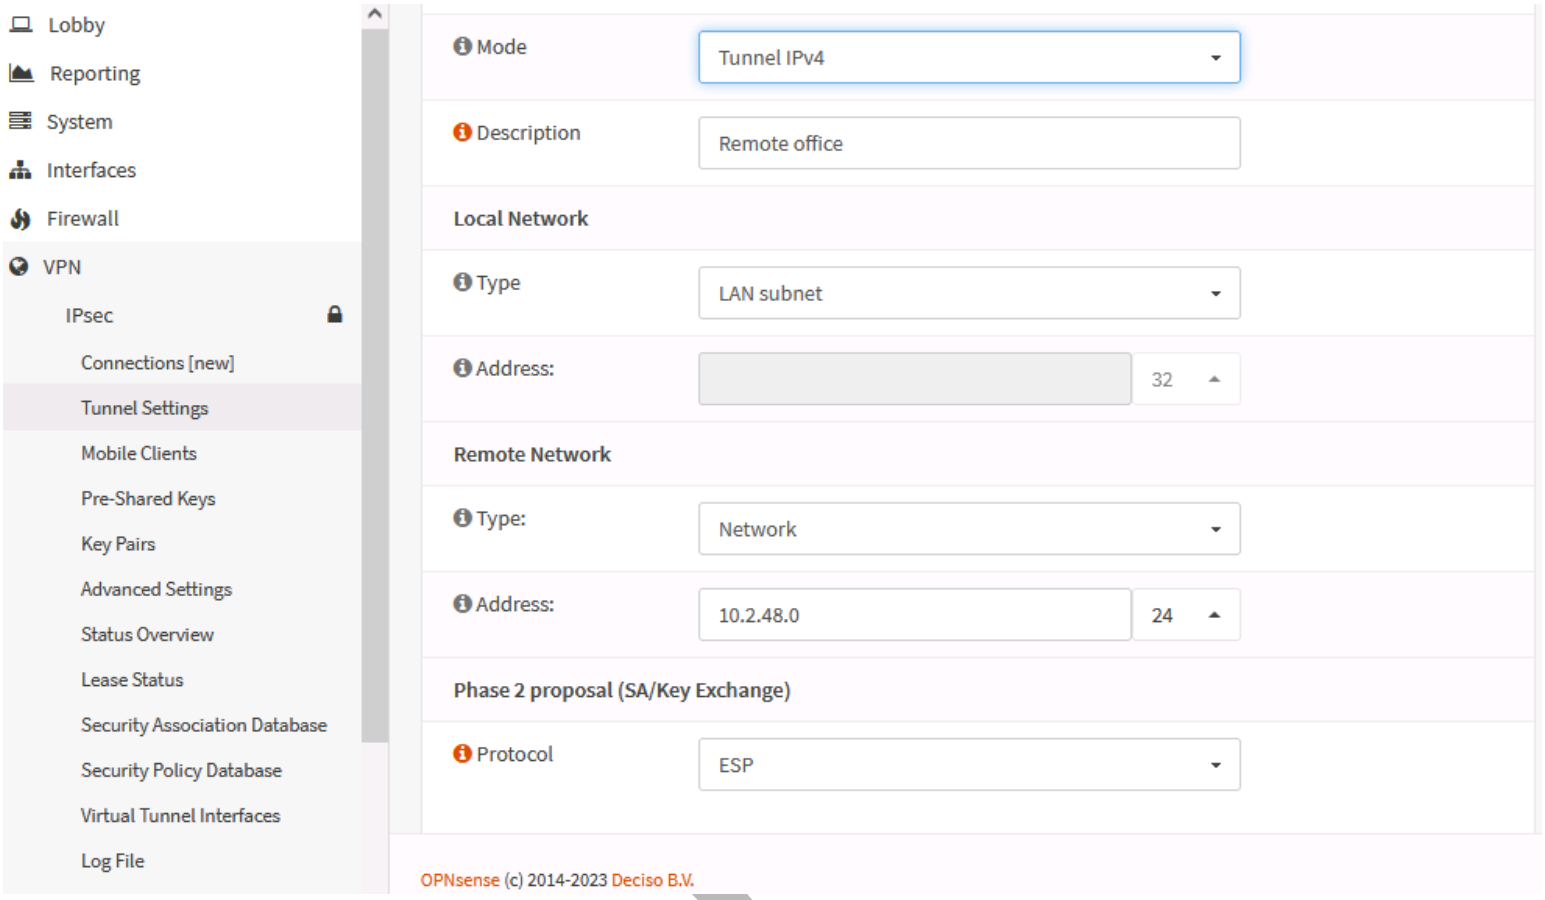
IPsec can be used in two modes:

Transport mode - is used to secure communications between hosts on a private network. When ESP is applied in transport mode, the IP header for each packet is not encrypted, just the payload data. If AH is used in transport mode, it can provide integrity for the IP header.

IPsec datagram using AH and ESP in transport mode.

Tunnel mode - is used for communications between VPN sites across an unsecured network. With ESP, the whole IP packet (header and payload) is encrypted and encapsulated as a datagram with a new IP header. AH has no use case in tunnel mode, as confidentiality is usually required.

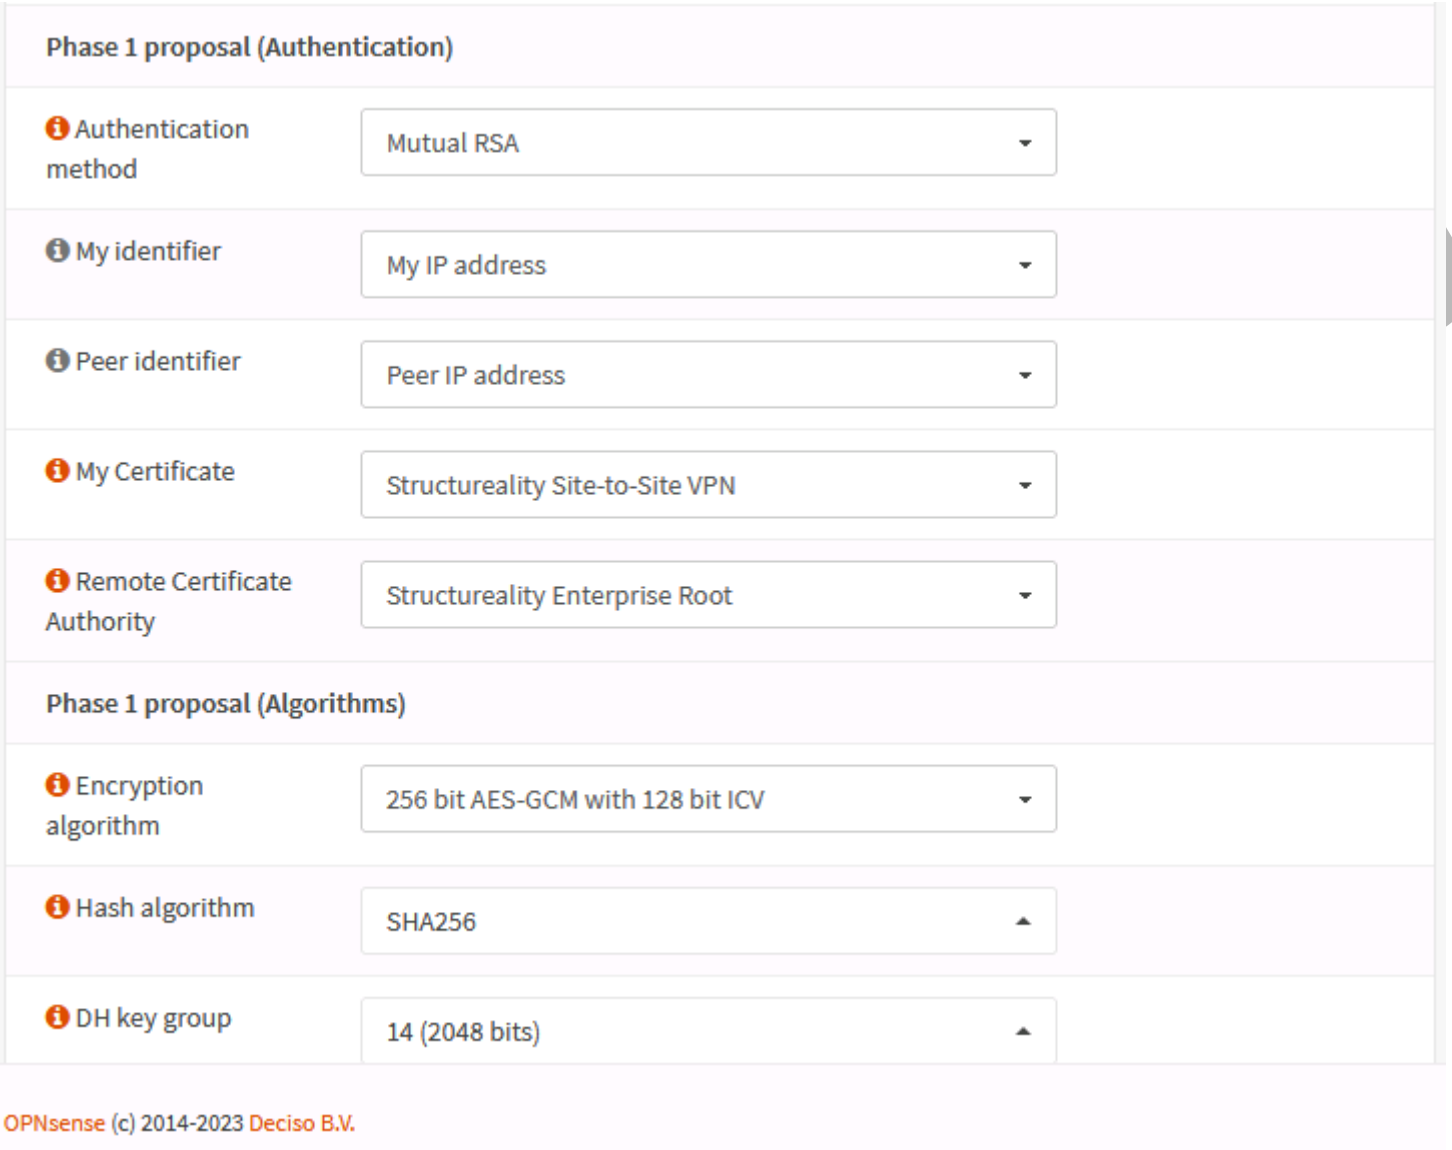
IPsec datagram using ESP in tunnel mode.



Configuring a site-to-site VPN using IPsec tunneling with ESP encryption in the OPNsense security appliance. (Screenshot courtesy of OPNsense.)

Each host or router that uses IPsec must be assigned a policy. An IPsec policy sets the authentication mechanism and the use of AH/ESP and transport or tunnel mode for a connection between two peers.

IPsec's encryption and hashing functions depend on a shared secret. The secret must be communicated to both peers, who must perform mutual authentication to confirm one another's identity. The Internet Key Exchange (IKE) protocol implements an authentication method, selects which cryptographic ciphers are mutually supported by both peers and performs key exchange. The set of properties is referred to as a security association (SA).



Configuring IKE for certificate-based authentication in the OPNsense security appliance. (Screenshot courtesy of OPNsense.)

IKE negotiations take place over two phases:

Phase I establishes the identity of the two peers and performs key agreement using the Diffie-Hellman algorithm to create a secure channel. Two methods of authenticating peers are commonly used:

Digital certificates - are issued to each peer by a mutually trusted certificate authority to identify one another.

Pre-shared key (group authentication) - is when the same passphrase is configured on both peers.

Phase II uses the secure channel created in Phase I to establish which ciphers and key sizes will be used with AH and ESP in the IPsec session.

There are two versions of IKE. Version 1 was designed for site-to-site and host-to-host topologies and required a supporting protocol to implement remote access VPNs. IKEv2 has some additional features that have made the protocol popular for use as a stand-alone remote access client-to-site VPN solution. The main changes are the following:

Supports EAP authentication methods, allowing, for example, user authentication against a RADIUS server.

Provides a simple setup mode that reduces bandwidth without compromising security.

Allows network address translation (NAT) traversal and MOBIKE multihoming. NAT traversal makes it easier to configure a tunnel allowed by a home router/firewall. Multihoming means that a smartphone client with Wi-Fi and cellular interfaces can keep the IPsec connection alive when switching between them.

8.7.7 Requiring IPsec for Communications (Demo Video)

Transcript:

In this demonstration, we'll look at requiring IPsec for communications between two network hosts. We'll use a Windows server and a Windows workstation.

To secure communications with IPsec, we use the Windows Defender Firewall with Advanced Security. Let's search for Windows Defender Firewall. There it is. Let's expand this. You'll notice that no rules are defined in the connection security rules here, so we need to define a new rule.
To define a new rule, you right-click Connection Security Rules and create a New Rule. The wizard displays. First, we choose the type of rule to use for IPsec. We have several options. We could configure an Isolation rule, which restricts connections based on authentication criteria such as domain membership or health status. We have an Authentication exemption, which will prevent authenticated connections with specific computers, in other words, it exempts computers from connecting.
We have Server-to-server rules. These authenticate connections between specified computers. Tunnel rules authenticate connections between two computers; it creates a tunnel between the two. We also can create Custom rules.
We want to set up an Isolation rule. We'll select Isolation. Click Next. Now, we need to specify how to enforce authentication. You can either request to use IPsec or require the use of IPsec. If you request, the default option is the computer that attempts to use IPsec. If either computer in the communication channel can't use IPsec, it fails over to unsecured communications.
Notice that this rule is applied to both inbound and outbound connections. If this rule isn't secure enough, then you can increase security by requiring IPSec for inbound and outbound connections. We'll request authentication for inbound and outbound connections. Click Next, which is the default option. Now, we determine the type of authentication method we want to use.
The first option, the Default, is to use whatever authentication methods are specified in the default IPsec settings. Most of the time, you'll use computer-based Kerberos. To use Kerberos, both computers must be in the same Active Directory forest.
You also have the option to specify Computer and user Kerberos. Choosing this option also requires both computers to be in the same Active Directory forest. The systems must be re-authenticated using user authentication.
In this demo, we'll use Computer authentication. There's also an Advanced option. After you select Advanced, click Customize. Customize allows you to set up multiple authentication methods. If the first method we set up fails, the system defaults to the next available authentication type. On the left, we specify the first authentication method. If we click Add, the options are a computer using Kerberos, a computer using NTLM, or a certificate from a trusted certificate authority.
That last option is useful if both computers aren't in the same Active Directory forest. In this case, we can use certificates to authenticate both ends of the communication channel. We'll configure both computers to trust the issuing CA of the certificates used on the computers. We'll browse through to select the certificates that we want to use.
We also have the option of using a pre-shared key that would be used by both computers. It's noted here that this isn't recommended. A pre-shared key is the least secure option of these four. Let's go ahead and click Cancel.
On the left, we specify the first authentication method. If the authentication doesn't work, the system will use the second authentication method we configured here on the right. For this demo, both hosts are members of the same domain, so we'll use computer-based Kerberos authentication. Now we'll click Next.
Now, we can specify the network location profile to which this rule will be applied. Because we have a desktop workstation and a server that are members of the same domain and will always be attached to the same network, we can select domain. However, if you have a roaming computer such as a laptop, notebook, or something of that sort, this becomes a little more of an issue.

While at work, the notebook or laptop would use the domain profile. When the computer is used from home or another location, it would use a public or private profile on the system, depending on where we connect. For our purposes today, we'll use all three of these profiles. We could turn one or more of them off if we wanted to restrict that. Now, we need to name this rule. We'll enter Request IPsec policy. Click Finish. At this point, the rule has been configured, but we've configured only one-half of the communication channel.

We'll go to the workstation side and configure the same rule here. On the workstation side, we'll go to the Search box and type Windows Defender Firewall with Advanced Security. We'll go to Connection Security Rules and right-click. We'll configure this IPsec rule like we did on the server system. Click Isolation and then Next. Now, we'll click Request authentication for inbound and outbound connections. We'll go to Computer Kerberos and leave all three. We'll name it Request IPsec and click Finish.

From the workstation, let's initiate communications between these two computers. We'll go back to the Search box and open a command prompt. We'll ping the IP address of the server system. If we don't know the IP address of the server system, we can go over to the server system, open the Command Prompt, and run ipconfig.

You can see the server address here: 172.16.50.110. Back to our workstation, ping 172.16.50.110. We want this to be a continuous ping, so we'll cancel and restart it with the -t flag to continuously send pings.

You can see we're getting replies from that address. That's perfect. We've established that we can ping the server. The pinging process will continue, and we can monitor the connection between the two computers.

We can see the replies from the server, and it just keeps running. Now, let's switch back to the server and go back to Windows Defender Firewall with Advanced Security. We can see the connection rule. Let's go to the Monitoring tab so we can monitor the connection.

If we go to the Connection Security Rule, we can see that the Request IPsec rule is currently in progress. We'll go to Security Associations. Here, we can look inside the Main Mode or Quick Mode and see the connections between our Windows 11 machine and server.

We see information that the connection is working. There are two modes, the main mode and quick mode because IPsec tunnels are built in two different phases. Phase one is called main mode. Phase two is quick mode. Breaking the monitoring information into these two modes is useful. It allows you to troubleshoot each phase of the connection establishment process.

Here, in Main Mode, we see information about the connection. We have the two endpoints here. We can see that this address here is the Windows Server. This is the workstation address here and the remote address.

We can also see that we're using Kerberos authentication here. We're not requiring a second authentication at the moment. If we scroll over or look at this side, we can see the encryption in the data integrity mode.

Let's right-click and go to Properties. We can see a little more information about the connection. Let's click Cancel. We can do the same thing for Quick Mode and see the same information. Again, we can see both ends of the communication: a local address and a remote address. We can see that AH and ESP are components of quick mode.

Before we leave Windows Defender Firewall with Advanced Security, we want to show you the global settings.

Recall earlier when we set up our rule. We right-clicked Connection Security Rules. From there, we clicked New Rule, Request authentication, and then authentication method. The default is to use the authentication method specified in IPsec settings.

Now, we can configure IPsec settings in the Windows Firewall with Advanced Security. That way, we don't have to manually configure these settings each time we set up a rule. We can use the default option. Let's select Cancel. Now, we'll go to Windows Defender Firewall with Advanced Security, right-click, go to Properties, and then go to the IPsec tab.

Here, we configure the IPsec setting defaults. These are the settings applied unless you override them manually when you create the rules. Let's click Customize. We can configure how the key exchange works. Select Advanced, then select Customize, and specify the Security methods used. We can enter a specific algorithm to use or specify key lifetimes. These are settings for the main mode; data protection is for quick mode.

If we click Advanced on data protection from quick mode and click Customize on this screen, we can configure the AH and ESP algorithms for data integrity and encryption. Note that we have the algorithm listed first or the algorithm that's used first. Remember that integrity ensures that the data hasn't been tampered with in transit; that's hashing. Encryption encrypts the data so that it can't be sniffed and read. Let's click Cancel. We can configure the default authentication method. We can set that to Computer Kerberos if we want. We used that when we set up the rule. Let's click Cancel because we don't want to set these defaults right now. Click Cancel again.

The last thing we need to review is the tools you can use to manage IPsec communications from the command line. Let's go to the command prompt. We'll type netsh advfirewall and ?. It displays the commands we have available. We'll use the consec command. Let's press Up and run the consec command.

Here, you see the commands available within this context. We can add a new connection, delete all matching connection security rules, display the configuration script, display a list of commands, set new values for properties of an existing rule, and display a specified connection security rule.

That's it for this demonstration. In this demonstration, we used IPsec to secure communications between two network hosts. We used Windows Firewall with Advanced Security to set up connection security rules on both sides of the communication.
We also set up secured communications between a Windows server system and a Windows client system. We then used the ping command to establish communications between the two hosts. We monitored the connection to verify that IPsec was being used to secure communications between them. We then talked about configuring the IPsec defaults. We ended this demonstration by talking about how you can manage IPsec rules from the command line.

8.7.8 Modify Enterprise Capabilities to Enhance Security

8.7.9 Practice Questions (Section Quiz)

q_sec_prot_ftps_01_secp8

Which of the following is a secure alternative to FTP that uses SSL for encryption?

Answers:

***FTPS**

SFTP

SCP

RCP

Explanation:

FTP Secure (FTPS) adds SSL or TLS to FTP to secure login credentials and encrypt data transfers. FTPS requires a server certificate.

Secure Shell File Transfer Protocol (SFTP) is a file transfer protocol that uses Secure Shell version 2(SSHv2) to secure data transfers. SFTP is not FTP that uses SSH, but rather a secure transfer protocol that is different from FTP.

Secure Copy Protocol (SCP) uses Secure Shell version 1 (SSHv1) to secure file transfers and login credentials.

Remote Copy Protocol (RCP) is an unsecured protocol for file transfer.

q_sec_prot_ftps_02_secp8

As a network administrator, you are asked to recommend a secure method for transferring data between hosts on a network.

Which of the following protocols would you recommend? (Select two.)

Answers:

RCP

***SCP**

FTP

***SFTP**

TDP

Explanation:

The Secure File Transfer Protocol (SFTP) is a file transfer protocol that uses Secure Shell (SSH) to secure data transfers. SSH ensures that SFTP transmissions use encrypted commands and data, which prevents data from being transmitted over the network in cleartext. The Secure Copy (SCP) protocol is associated with Unix/Linux networks and is used to transfer files between systems. Like SFTP, SCP relies on SSH to ensure that data and passwords are not transmitted over the network in clear text.

The Remote Copy Protocol (RCP) and the File Transfer Protocol (FTP) are used to transfer files between computers. However, both are unsecured protocols and transmit data over the network in cleartext. Data and passwords sent over the network in clear text are in danger of being tampered with or read during transmission, making them inappropriate for many network applications.

The Tag Distribution Protocol (TDP) is a two-party protocol that runs over a connection-oriented transport layer with guaranteed sequential delivery. Tag-switching routers use this protocol to communicate tag-binding information to their peers. However, it is not a protocol used as a secure method for transferring data between hosts on a network.

q_sec_prot_https_01_secp8

Which of the following protocols uses port 443?

Answers:

***HTTPS**

S/MIME

SSH

S-HTTP

Explanation:

Hyper Text Transfer Protocol Secure (HTTPS) is a secure form of HTTP that uses SSL or TLS to encrypt sensitive data before it is transmitted. HTTPS uses port 443.

Secure Hypertext Transfer Protocol (S-HTTP) supports a wide variety of encryption methods, but it does not use port 443.

SSH uses port 22. S/MIME is a method for encrypting emails.

S/MIME does not communicate over a specific port number.

q_sec_prot_https_02_secp8

Which TCP/IP protocol is a secure form of HTTP that uses SSL as a sub-layer for security?

Answers:

***HTTPS**

SMTP

SSH

DNS

Explanation:

HTTPS is a secure form of HTTP that uses SSL as a sub-layer for security.

SMTP is used to route electronic mail through the internetwork.

SSH allows secure interactive control of remote systems.

DNS is a system that is distributed throughout the internetwork to provide address/name resolution.

q_sec_prot_https_03_secp8

Which protocol is used to browse a website securely?

Answers:

***HTTPS**

SSH

UDP

SIP

ARP

Explanation:

HTTPS is a secure form of HTTP that uses SSL to encrypt data before it is transmitted. HTTP is used by web browsers and web servers to exchange files (such as web pages) through the World Wide Web and intranet.

SSH is used for secure remote management.

UDP is a data transport control protocol that does not include error correction or detection mechanisms.

SIP is a protocol used by voice over IP (VoIP) to set up and terminate phone calls.

ARP is used by devices to find the IP address of a device with a known MAC address.

q_sec_prot_https_04_secp8

A defense contractor has tasked its local network administrator with securing communications between the organization's web server and clients to protect sensitive user information.

Which protocol should the network administrator choose to achieve this security objective?

Answers:

HTTP

Telnet

***HTTPS**

SSH

Explanation:

Hypertext Transfer Protocol Secure (HTTPS) is the secure alternative to HTTP. It uses encryption to protect transmitted data, making it the appropriate choice for securing sensitive user information, such as login credentials and data entered in form fields.

In contrast, HTTP, an insecure protocol, transmits data in clear text format, which makes it unsuitable for securing sensitive information.

Similarly, Telnet is another insecure protocol that the organization should avoid due to its lack of encryption, making it unsuitable for securing sensitive data and login information.

While Secure Shell (SSH) is a secure protocol for connecting to servers and equipment, it is not the appropriate choice for securing communication between a web server and clients.

q_sec_prot_https_05_secp8

A rapidly growing startup relies primarily on web servers for its operations, focusing almost exclusively on Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) traffic.

In the context of this focus and the need for enhanced security, which action should the company prioritize to ensure controlled outgoing network communication?

Answers:

***Allow only ports 80 and 443 for incoming traffic and restrict unnecessary outgoing protocols.**

Permit all incoming and outgoing traffic.

Restrict outgoing traffic to only port 25.

Block only incoming requests from private Internet Protocol addresses.

Explanation:

Allowing ports 80 and 443 for incoming and restricting unnecessary outgoing protocols aligns with the need for HTTP and HTTPS traffic and reduces potential security risks by restricting unnecessary outgoing protocols.

Permitting all incoming and outgoing traffic doesn't follow the principle of least privilege. It opens the network to potential threats by not regulating the type of traffic that enters or leaves, thus significantly increasing security risks.

Restricting all outgoing traffic to only port 25, used by Simple Mail Transfer Protocol for email transfer, is unnecessarily limiting. It doesn't consider the required HTTP and HTTPS traffic and could inadvertently block legitimate network communication.

Blocking only private incoming requests doesn't account for the specific incoming and outgoing traffic restrictions needed.

q_sec_prot_remote_01_secp8

Which of the following tools allow remote management of servers? (Select two.)

Answers:

***SSH**

***Telnet**

FTP

POP3

SSL

Explanation:

Both Telnet and SSH are tools for remote server management.

POP3 is for retrieving email from a remote server, and FTP is for transferring files.

Secure Socket Layer (SSL) secures messages being transmitted on the internet.

q_sec_prot_remote_02_secp8

You are a network administrator for a large corporation that has recently transitioned to a remote work model due to unforeseen circumstances. One of your tasks is to ensure secure remote access for all employees. You have decided to use a remote desktop protocol (RDP) for this purpose.

However, you are aware of the security risks associated with RDP and want to ensure that the connection is as secure as possible.

Which of the following actions would be the most effective in enhancing the security of your RDP connection?

Answers:

Disable Network Level Authentication (NLA).

Use a non-standard port for RDP.

Enable RDP on all company devices.

***Implement two-factor authentication.**

Explanation:

Implement two-factor authentication is the correct answer. Two-factor authentication adds an additional layer of security by requiring users to verify their identity using a second factor, typically a mobile device, in addition to their regular username and password. This makes it much more difficult for an attacker to gain access even if they have obtained a user's credentials.

Disabling Network Level Authentication (NLA) is an incorrect answer. NLA provides an extra layer of authentication before a session is established with the server, which helps to prevent unauthorized access.

Using a non-standard port for RDP is an incorrect answer. While this might obscure the RDP service from casual scanning, it does not provide any real security. Port scanning can still reveal the RDP service, and this method does nothing to protect against brute-force attacks or vulnerabilities in the RDP service itself.

Enabling RDP on all company devices is an incorrect answer. Enabling RDP on all devices increases the attack surface and could potentially allow an attacker to gain access to the network if a device is compromised. It's better to limit RDP access to only those devices that need it.

q_sec_prot_ssh_01_secp8

Which of the following protocols can be used to manage a network device from a remote connection securely?

Answers:

***SSH**

Telnet

SFTP

TLS

Explanation:

SSH allows for secure interactive control of remote systems. SSH is a secure and acceptable alternative to Telnet.

Telnet is a network protocol that allows a user on one computer to log into another computer that is part of the same network. However, it does not provide for secure management from a remote connection.

SFTP is a file transfer protocol that uses Secure Shell (SSH) to secure data transfers.

TLS ensures that messages transmitted on the internet are private and tamper-proof. TLS is often used to add security to other protocols.

q_sec_prot_ssh_02_secp8

SFTP uses which mechanism to provide security for authentication and data transfer?

Answers:

IPsec

Token devices

SSL

***SSH**

Explanation:

SSH File Transfer Protocol uses Secure Shell (SSH) to provide security for authentication and data transfer.

FTPS uses SSL to secure FTP traffic. You can also secure FTP traffic by establishing an IPsec tunnel between the client and the server, but IPsec is established independently of FTP in this case.

A token is a device that employs an encrypted key for which the encryption algorithm is the method of generating an encrypted password known to a network's authentication server. There are both software and hardware tokens. However, it does not provide security for data transfer.

Secure Sockets Layer (SSL) is an encryption security protocol for data. However, it does not provide for secure authentication.

q_sec_prot_ssh_03_secp8

Telnet is inherently insecure because its communications are in plaintext and easily intercepted.

Which of the following is an acceptable alternative to Telnet?

Answers:

SLIP

SHTTP

Remote Desktop

***SSH**

Explanation:

SSH (Secure Shell) is a secure and acceptable alternative to Telnet. SSH allows for secure interactive control of remote systems. SSH uses RSA public key cryptography for both connection and authentication. SSH uses the IDEA algorithm for encryption by default. But it is also able to use Blowfish and DES.

Serial Line Internet Protocol (SLIP) is the protocol TCP/IP uses when operating through a serial connection. It does not provide for remote connections.

Secure HTTP (SHTTP) encrypts data transfer but does not authentic to a client and is not a remote networking protocol.

Remote Desktop, while a remote control mechanism, is limited in use to a few versions of Windows and is not very secure.

q_sec_prot_ssh_04_secp8

What is the default encryption algorithm used by SSH (Secure Shell) to protect data traffic between a client and the controlled server?

Answers:

***IDEA**

DES

AES

Blowfish

Explanation:

SSH uses the IDEA algorithm for encryption by default. SSH (Secure Shell) is a secure and acceptable alternative to Telnet. SSH allows for secure interactive control of remote systems. SSH uses RSA public key cryptography for both connection and authentication.

SSH can use Blowfish or DES, but these are not the default methods.

SSH does not support AES (not SSH-2, at least).

q_sec_prot_ssl_01_secp8

You are purchasing a hard disk from an online retailer over the internet.

What does your browser MOST LIKELY use to ensure that others cannot see your credit card number on the internet?

Answers:

VPN

PPTP

***SSL**

IPsec

Explanation:

Your web browser uses SSL (Secure Sockets Layer) to ensure safe web transactions. URLs that begin with HTTPS:// trigger your web browser to use SSL.

A virtual private network (VPN) protects users by encrypting their data and masking their IP addresses. However, in this scenario, it would not normally be used to secure a credit card number during a transaction. SSL would be more likely to be used.

Point-to-Point Tunneling Protocol (PPTP) is a network protocol that enables the secure transfer of data from a remote client to a private enterprise server by creating a virtual private network (VPN) across TCP/IP-based data networks. Once again. the more common way of securing data during a transaction in a browser (such as a credit card number) is to use SSL.

IPSec is a set of communication rules or protocols for setting up secure connections over a network. However, in this scenario, the transaction is being made over the Internet through a web browser.

q_sec_prot_ssl_02_secp8

Which protocol does HTTPS use to offer greater security in web transactions?

Answers:

Kerberos

***SSL**

IPsec

Telnet

Explanation:

HTTPS uses Secure Sockets Layer (SSL) to offer greater security in web transactions.

Kerberos allows individuals communicating over a non-secure network to prove their identity to one another in a secure manner.

IPsec (IP security) is a suite of protocols for securing Internet Protocol (IP) communications by authenticating and encrypting each IP packet in a data stream.

Telnet is a tool for remote server management.

q_sec_prot_ssl_03_secp8

SSL (Secure Sockets Layer) operates at which layer of the OSI model?

Answers:

Application

Presentation

***Session**

Transport

Explanation:

SSL (Secure Sockets Layer) operates at the Session layer of the OSI model.

SSL operates over TCP port 443. SSL was developed by Netscape to secure internet-based client/server interactions. SSL authenticates the server to the client using public key cryptography and digital certificates, and this protocol encrypts the entire communication session between a server and a client. SSL can be used to protect web (HTTP) traffic as well as Telnet, FTP, and emails.

SSL does not operate at the Application layer, as this is where human interaction takes place, or the Presentation level, where the data is ensured to be in a usable format.

The Transport layer simply represents data being transmitted using various protocols, which is one layer below the Session layer.

q_sec_prot_ssl_04_secp8

When using SSL authentication, what does the client verify first when checking a server's identity?

Answers:

The certificate must be non-expiring and self-signed by the sysadmin.

***The current date and time must fall within the server's certificate-validity period.**

All DNS resolutions must point to the corporate intranet routers.

Master secrets are verifiable from asymmetric keys.

Explanation:

An SSL client first checks the server's certificate validity period. The authentication process stops if the current date and time fall outside of the validity period.

SSL clients verify a server's identity using the following steps:

The client checks the server's certificate validity period. The authentication process stops if the current date and time fall outside of the validity period.

The client verifies that the issuing certificate authority (CA) is on its list of trusted CAs.

The client uses the CA's public key to validate the CA's digital signature on the server certificate. If the digital signature can be verified, the client accepts the server certificate as a valid certificate issued by a trusted CA.

To protect against man-in-the-middle attacks, the client compares the actual DNS name of the server to the DNS name on the certificate.

q_sec_prot_ssl_05_secp8

You want to allow traveling users to connect to your private network through the internet. Users connect from various locations, including airports, hotels, and public access points like coffee shops and libraries. As such, you won't be able to configure the firewalls that might be controlling access to the internet in these locations.

Which of the following protocols would MOST likely be allowed through the widest number of firewalls?

Answers:

PPTP

L2TP

***SSL**

IPsec

PPPoE

Explanation:

Ports must be opened in firewalls to allow VPN protocols. For this reason, using SSL for the VPN often works through firewalls when other solutions do not because SSL uses port 443. Port 443 is often already open to allow HTTPS traffic. In addition, some NAT solutions do not work well with VPN connections.

PPTP uses port 1723, L2TP uses ports 1701 and 500, and IPsec uses UDP port 500 for the Internet Key Exchange (IKE) Protocol.

PPP over Ethernet (PPPoE) is used for connections with an always-on state, such as DSL or fiber-optic-running Ethernet. PPPoE is a modification of PPP that allows for the negotiation of additional parameters that aren't typically present on a regular Ethernet network. ISPs typically implement PPPoE to control and monitor internet access over broadband links.

q_sec_prot_ssl_cookies_secp8

A large e-commerce development team created a new web application to manage customer transactions. The application handles sensitive user data, including personal information and payment details.

The security team had concerns about potential security risks and took action to implement specific security measures to protect the application.

Which security measures should the team implement to safeguard the web application and user data? (Select two.)

Answers:

***Secure cookies**

***Secure socket layer (SSL) certificates**

Code signing

Input validation

Network monitor

Explanation:

Secure cookies play a crucial role in safeguarding sensitive user data during web transactions. When transmitted over encrypted connections, the "Secure" attribute of cookies reduces the risk of unauthorized access and data exposure, ensuring the protection of user privacy and maintaining the web application's integrity.

Secure Socket Layer (SSL) certificates are pivotal in securing web applications and user data through data encryption, integrity, and authentication.

Code signing is essential for software authentication but is not directly relevant to web applications and the security of user data during web transactions.

Input validation is also important for security, but it focuses on preventing data-related vulnerabilities and does not directly address the protection of user data during web transactions.

Network monitoring collects and reports on a variety of data from a computer network, including routers, switches, firewalls, load balancers, and even endpoints, like servers and workstations. However, it would not provide any security for the website or user data.

q_sec_prot_ssl_tls_secp8

Which of the following protocols are often added to other protocols to provide secure transmission of data? (Select two.)

Answers:

***TLS**

***SSL**

HTTPS

SMTP

SNMP

Explanation:

Both Secure Sockets Layer (SSL) and Transport Layer Security (TLS) are protocols that are used with other protocols to add security. In addition, Secure Shell (SSH) can be used to add security when using unsecured protocols.

HTTPS is the secure form of HTTP that uses SSL.

SMTP is used for sending email.

SNMP is a network management protocol.

q_sec_prot_tls_01_secp8

Which of the following protocols can TLS use for key exchange? (Select two.)

Answers:

***Diffie-Hellman**

***RSA**

IKE

KEA

ECC

Explanation:

TLS uses Diffie-Hellman or RSA to exchange session keys.

SSL uses RSA or Key Exchange Protocol (KEA) for key exchange.

IPsec uses IKE for key exchange.

ECC (elliptic curve cryptography) is a method that can be used in key exchange.

q_sec_prot_tls_02_secp8

Which of the following statements about applying common security techniques to computing resources is correct?

Answers:

SSL is primarily for securing FTP communications.

HTTPS operates over port 80 by default.

***TLS 1.3 prevents downgrade attacks and reduces the number of handshake messages.**

A cipher suite in TLS 1.3 includes RSA signatures for symmetric bulk encryption.

Explanation:

Transport Layer Security (TLS) removes the ability to perform downgrade attacks, making it more secure. It also introduces changes to the handshake protocol, reducing the number of messages and speeding up connections.

Netscape developed Secure Sockets Layer (SSL) in the 1990s to address the lack of security in HTTP, not File Transfer Protocol (FTP).

HTTPS operates over port 443 by default.

In TLS 1.3, cipher suites no longer include key exchange and RSA signature algorithms for bulk encryption.

q_ipsec_ah_esp_01_secp8

IPsec is implemented through two separate protocols.

What are these protocols called? (Select two.)

Answers:

***AH**

***ESP**

SSL

EPS

L2TP

Explanation:

IPsec is implemented through two separate protocols, which are IP Authentication Header and IPsec Encapsulating Security Payload. IPsec AH provides authentication and non-repudiation services to verify that the sender is genuine and data has not been modified in transit. IPsec ESP provides data encryption services for the data within the packet.

SSL, EPS, and L2TP are not protocols associated with IPsec.

q_ipsec_ah_esp_02_secp8

Which of the following network layer protocols provides authentication and encryption services for IP-based network traffic?

Answers:

TCP

***IPsec**

SSL

L2TP

Explanation:

IPsec is a security implementation that provides security for all other TCP/IP-based protocols that operate above the Network layer. IPsec provides authentication through a protocol called IPsec Authentication Header (AH) and encryption services through a protocol called IPsec Encapsulating Security Payloads (ESP).

The Transmission Control Protocol (TCP) is a Transport layer connection protocol that provides data transmission services. It is not a secure protocol and relies on other measures, such as IPsec, to provide security.

Secure Sockets Layer (SSL) is an Application and Session layer protocol that is designed to secure network traffic from certain other protocols, such as HyperText Transfer Protocol (HTTP) and Post Office Protocol version 3 (POP3). It does not provide security for protocols lower in the TCP/IP protocol stack, such as TCP and UDP.

Layer 2 Tunneling Protocol (L2TP) is a protocol used to encapsulate Point-to-Point Protocol (PPP) traffic.

q_ipsec_ah_esp_03_secp8

What is the primary function of the IKE Protocol used with IPsec?

Answers:

***Create a security association between communicating partners.**

Encrypt packet contents.

Provide authentication services.

Provide both authentication and encryption.

Ensure dynamic key rotation and select initialization vectors (IVs).

Explanation:

Internet Key Exchange (IKE) Protocol is used with IPsec to create a security association between communicating partners. It controls the negotiation of encryption methods, identifies how keys are exchanged, and sets up other parameters that control communications.

Encapsulating Security Payload (ESP) provides both authentication and encryption, while Authentication Header (AH) provides authentication only.

IKE, by itself, ensures dynamic key rotation and selects initialization vectors (IVs). But this functionality is not completely utilized by IPsec.

q_ipsec_ike_01_secp8

The IT department at a software development company is setting up a VPN for employees.

The tunneling protocol the department uses must encrypt network connections at the packet level. The connection needs to support mutual authentication as well as low packet overhead.

Which setup should the team choose?

Answers:

***An IPsec tunnel with Internet Key Exchange (IKE) for mutual authentication.**

A Transport Layer Security (TLS) tunnel with extensible authentication protocol (EAP) for mutual authentication.

An IPsec tunnel with Secure Sockets Layer (SSL) for mutual authentication.

A TLS tunnel with PPTP (Point-to-Point Tunneling Protocol) for mutual authentication.

Explanation:

IPsec operates at the network layer and protects secure VPN connections at the packet level. It can also perform mutual authentication using IKE, meeting all the team's requirements.

While TLS tunnels can use EAP to perform mutual authentication, they operate at the application level and do not operate on the network layer, so they can only secure a connection between two applications.

IPsec can utilize SSL through IKEv2, but IPsec establishes mutual authentication itself and does not typically use SSL for that purpose.

PPTP is an easily breachable legacy protocol from the 1990s. Though it can use EAP-TLS for mutual authentication, it is not secure and can expose the connection to offline cracking.

q_ipsec_ike_02_secp8

A software development company has implemented an IPsec tunnel with Internet Key Exchange (IKE) for mutual authentication as part of its Virtual Private Network (VPN) setup for employees.

The company chooses this solution for its ability to encrypt network connections at the packet level and support mutual authentication with low packet overhead.

What benefits do the IT department likely aim to achieve with this setup?

Answers:

***Protection at the packet level with mutual authentication**

Secure application-level connections

Mutual authentication using SSL

Reliability of an established legacy protocol

Explanation:

Internet Protocol Security (IPsec) operates at the network layer, protecting secure VPN connections at the packet level. It also uses Internet Key Exchange (IKE) to perform mutual authentication, which aligns with the team's requirements.

The chosen setup does not likely benefit from using Transportation Layer Security (TLS) tunnels to secure application-level connections between two applications.

IPsec can utilize Secure Sockets Layer (SSL) through IKEv2, but it typically establishes mutual authentication and does not use SSL for that purpose.

Point-to-Point Tunneling Protocol (PPTP) is known to be easily breached and does not align with the team's requirements, despite older protocols that might appear tried-and-tested.

q_ipsec_remote_access_secp8

A company is setting up a secure remote access solution for its employees.

\Which of the following provides the MOST secure method for remote access?

Answers:

***A virtual private network (VPN) with Internet Protocol Security (IPSec)**

A jump server

A Layer 4 firewall

A proxy server

Explanation:

A virtual private network (VPN) with Internet Protocol Security (IPSec) provides a secure, encrypted connection for remote access, the most secure option.

While a jump server provides a controlled means of access, it does not offer the same level of security as a VPN with IPSec.

A Layer 4 firewall operates at the transport layer and provides security measures but cannot provide secure remote access. It controls access based on port numbers and protocols but cannot inspect traffic at a deeper level.

A proxy server operates at the application layer and provides some security measures but cannot provide secure remote access. It does not provide end-to-end encryption or advanced security measures for secure remote access.

q_ipsec_tls_vpn_secp8

A software company has a team of developers working remotely from different locations. They need to connect to the company's server to access and update code repositories.

The company wants to ensure that the connection is secure and that both the server and the client can authenticate each other.

Which type of VPN setup would be MOST appropriate for this scenario?

Answers:

Site-to-site VPN

Host-to-host VPN

***Transport layer security (TLS) VPN**

Point-to-Point Tunneling Protocol (PPTP) VPN

Explanation:

Transport Layer Security (TLS) VPN is the correct answer. A TLS VPN allows the client to connect to the remote access server using digital certificates. This allows for mutual authentication, where both server and client prove their identity to one another. It's the best choice for a scenario where multiple clients need to connect to a server securely and mutual authentication is required.

Site-to-site VPN is used to connect two or more networks, such as two offices in different locations. It wouldn't be the best choice for this scenario as the developers are working remotely from different locations and need to connect individually to the company's server.

Host-to-host VPN is used to secure traffic between two specific computers. While it could be used for a connection between a developer's computer and the company server, it wouldn't be the most efficient solution for a team of developers working from different locations.

Point-to-Point Tunneling Protocol (PPTP) VPN is an older VPN protocol that has been largely deprecated due to security vulnerabilities. It wouldn't be the best choice for a scenario where security is a priority.

q_ipsec_transport_mode_secp8

You are a senior network engineer tasked with implementing IPsec in her organization to enhance network security.

The organization has a hybrid network infrastructure with on-premise and cloud-based resources. The organization also has remote employees who access the network via VPN. You are considering using the Authentication Header (AH) protocol and are unsure about the mode of operation to use.

Which mode should you choose and why?

Answers:

***Transport mode because it provides sufficient security while maintaining high network performance.**

Tunnel mode because it provides an extra layer of security by encrypting the entire packet.

Transport mode because it is more compatible with the VPN used by remote employees.

Tunnel mode because it is more suitable for a hybrid network infrastructure.

Explanation:

Transport mode is the correct choice in this scenario. While it only encrypts the payload of the packet and not the entire packet, it provides sufficient security for the data being transmitted. Furthermore, because it is less resource-intensive than tunnel mode, it helps maintain high network performance, which is crucial in a hybrid network environment with potentially varying network speeds and capacities.

Tunnel mode does provide an extra layer of security by encrypting the entire packet. However, it is more resource-intensive and could potentially impact network performance. In a hybrid network environment where network performance is crucial, this could be a disadvantage.

Transport mode is not necessarily more compatible with VPNs used by remote employees. The compatibility with VPNs depends on various factors, including the type of VPN used and the specific VPN configuration.

While tunnel mode might seem more suitable for a hybrid network infrastructure because it encrypts the entire packet, it is not the best choice in this scenario due to its potential impact on network performance. In a hybrid network environment, maintaining high network performance is often a priority, making transport mode a better choice.

q_ipsec_tunnel_mode_secp8

You are a network administrator tasked with implementing IPsec to secure data transmission over the company's unprotected TCP/IP network.

You decide to use the Encapsulating Security Payload (ESP) protocol for its confidentiality feature. However, you are unsure whether to use transport mode or tunnel mode. The company's network includes several routers and switches, and it also uses Network Address Translation (NAT).

Which mode should you choose and why?

Answers:

Transport mode because it only encrypts the payload, making it faster and more efficient.

Tunnel mode because it encrypts the entire packet, providing an extra layer of security.

Transport mode because it is more compatible with NAT.

***Tunnel mode because it is more compatible with NAT.**

Explanation:

Tunnel mode is the correct choice because it is more compatible with NAT. In tunnel mode, the entire original IP packet (including the header) is encrypted and encapsulated into a new packet. This allows the packet to traverse through NAT devices without the NAT modifications causing issues, as the modifications are made to the outer packet, not the encrypted original packet.

Transport mode only encrypts the payload, not the entire IP packet. While this might be faster and more efficient, it does not provide the level of security needed when traversing multiple network devices and dealing with NAT.

Tunnel mode does provide an extra layer of security by encrypting the entire IP packet. However, the reason to choose tunnel mode in this situation is not solely because of the extra security it provides.

Transport mode is not more compatible with NAT. NAT changes IP headers, which can cause communication errors with an IPsec VPN tunnel. Transport mode, which does not encrypt the IP header, can have issues when the IP header is modified by NAT.

q_ipsec_vpn_site-to-site_secp8

A multinational corporation with headquarters in New York and branches in London, Tokyo, and Sydney wants to securely connect all their offices to share resources and data.

The IT department has been tasked with setting up a secure network connection.

Which type of VPN setup would be the MOST appropriate for this scenario?

Answers:

Remote access VPN

Host-to-host VPN

***Site-to-site VPN**

Client-to-site VPN

Explanation:

Site-to-site VPN is the correct answer. A site-to-site VPN connects two or more networks, such as two offices in different locations. In this scenario, it would allow the corporation's offices in New York, London, Tokyo, and Sydney to share resources and data securely.

Remote access VPN is typically used by individual users or telecommuters to connect to a corporate network from a remote location. While it would allow employees to access the company's network from home or while traveling, it would not connect the company's offices to each other.

Host-to-host VPN is used to secure traffic between two specific computers, typically in a situation where the private network is not trusted. It would not be suitable for connecting multiple sites of a multinational corporation.

Client-to-site VPN is similar to a remote access VPN, where individual users or devices connect to a corporate network from a remote location. It would not be suitable for connecting multiple offices of a multinational corporation.

8.8 Web Application Security

As you study this section, answer the following questions:

What are the common forms of web application attacks?

How do you mitigate replay attacks?

What are some methods to prevent driver manipulation?

How does SSL stripping work?

In this section, you will learn to:

Clear the browser cache.

Prevent cross-site scripting.

Exploit SQL on a webpage.

Perform an SQL injection attack.

The key terms for this section include:

Term	Definition
Privilege escalation	The exploitation of a misconfiguration, a bug, or design flaw to gain unauthorized access to resources.
Pointer/object dereferencing	An attack that retrieves a value stored in memory that can be exploited through a NULL pointer dereference.
Buffer overflow	An attack that exploits an operating system or an application that does not properly enforce boundaries for inputting data such as the amount of data or the type of data.
Resource exhaustion	An attack that focuses on depleting the resources of a network to create a denial-of-service to legitimate users.
Memory leak	A leak that happens when dynamic memory is allocated in a program, but no pointers are connected to it causing it to never be returned when requested.
Race conditions	A sequence of events with dependencies that a system is programmed to run in a certain order which can lead to a time-of-check to time-of-use bug vulnerability.
Error handling	The procedures in a program that respond to irregular input or conditions.
Improper input handling	The lack of validation, sanitization, filtering, decoding, or encoding of input data.
Replay attack	An attack that happens when network traffic is intercepted by an unauthorized person who then delays or replays the communication to its original receiver, acting as the original sender. The original sender is unaware of this occurrence.
Pass the hash	An attack in which an attacker obtains a hashed password and uses it to gain unauthorized access.
API attacks	A malicious use of an API (application programming interface).
SSL stripping	An attack that focuses on stripping the security from HTTPS-enabled websites.
Driver manipulation	An attack that focuses on device drivers. The attack uses refactoring or shimming.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.3 Explain various types of vulnerabilities. Application Memory injection Buffer overflow Race conditions Time-of-check (TOC) Time-of-use (TOU) Malicious update Web-based Structured Query Language injection (SQLi) Cross-site scripting (XSS) Hardware Zero-day 2.4 Given a scenario, analyze indicators of malicious activity. Application attacks Injection Buffer overflow Replay Privilege escalation Directory traversal 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Patching 3.2 Given a scenario, apply security principles to secure enterprise infrastructure.

	Infrastructure considerations Intrusion prevention system (IPS)/intrusion detection system (IDS) 4.1 Given a scenario, apply common security techniques to computing resources. Application security Secure cookies 4.6 Given a scenario, implement and maintain identity and access management. Single sign-on (SSO) Lightweight Directory Access Protocol (LDAP)
TestOut Security Pro	3.2 Implement application defenses 3.2.3 Configure web application security 3.2.5 Configure browser settings

8.8.1 Web Application Attacks (Lesson Video)

Transcript:

Applications are used extensively in all devices, including computers, servers, mobile devices, and more. Oftentimes, these applications have access to critical components of the operating system. Attackers will target application vulnerabilities to gain elevated privileges, crash the system, access the network, steal sensitive data, and more. In this lesson, we'll look at some of the common vulnerabilities and attacks you need to be aware of and some steps you can take to mitigate them.

When an attacker gains access to a system, one of their first goals is to gain enough privileges to execute their own code on the target system, known as arbitrary code execution. There are two types of privilege escalation.
The first is horizontal escalation, which happens when the attacker accesses functionality or data that belongs to another user with the same privilege level they currently have, such as a co-worker. This type of escalation is usually only focused on gaining access to that particular account.
Vertical escalation is the more common escalation type. It occurs when the attacker gains access to an account with a higher-level access than they currently have, such as an administrator account. Vigilant monitoring and proper implementation of access control security measures, such as strong passwords and implementing the principle of least privilege, will go a long way in protecting against escalation attacks.
Now, let's look at memory injection attacks. These attacks occur when the attacker injects malicious code into a running application's process memory. One of the more common types is an overflow attack. An overflow occurs when a program is designed only to handle a certain amount of data, but the attacker sends more data, which can cause the system to crash or behave in unexpected ways. The most common of these is the buffer stack overflow, which targets the stack of a program. To better understand this, let's look at how programs are put together.
Overflow attacks are one of the most dangerous types of attacks. The main cause of these attacks is errors in programming. The best way to defend against these attacks is to use proper programming practices and avoid programming functions known to be vulnerable. Thankfully, many modern languages, such as Python and Java, have built-in controls to prevent overflow attacks.
A replay attack, also known as a session replay or session hijack, exploits the session cookies that are generated when you connect to a web application. These cookies allow the application to identify the user and prove that they've been

authenticated. The hacker can intercept the cookie using an on-path attack and then forge their own cookie file to establish a session with the web application. This allows the attacker to gain access to the victim's account without knowing their credentials.
To prevent this form of attack, use a strong digital signature with timestamps, session keys that are time-bound and process-bound, and sequence numbers. Authentication systems can be programmed to accept network packets with valid timestamps and sequence numbers.
The last attack we'll look at is the malicious update. This occurs when a software program update seems legitimate but contains malicious code. This can happen when the software's website is hacked, and the update file is replaced with the malicious one. This type of attack is particularly devastating because it not only harms the victims but can also destroy the reputation of the software developer. Malicious updates can be difficult to protect against, but secure software supply chain management, digital signature verification, and other software security practices help mitigate these risks.
That'll wrap up this lesson on web application attacks. In this lesson, we reviewed some common attacks you should be aware of, including escalation attacks, memory injection attacks, replay attacks, race conditions, and malicious updates. We also looked at some security measures we can take to help mitigate each of these attacks.

8.8.2 XSS and CSRF Attacks (Lesson Video)

Transcript:

FILE NOT FOUND

8.8.3 Injection Attacks (Lesson Video)

Transcript:

In this lesson, we're going to talk about injection attacks. We're going to focus on LDAP, XML, and command injection attacks and a variation called the directory traversal attack.

A lightweight directory access protocol, or LDAP, injection attack is used to exploit a web-based application. If the application fails to properly validate the input in the form fields, then it's possible for the wrong commands to be constructed. This could potentially provide an attacker with unauthorized access to the LDAP directory tree. They may be able to view more information than they should have access to, or even modify it.
Suppose we have an application that uses LDAP calls to communicate with the directory tree. Client workstations can access the web server, load the application's web page, and query the directory services tree.
Here, if the user supplies an invalid value, or a malicious value, unexpected behavior can occur. For example, suppose the user puts an asterisk (*) in this field and submits the form. Depending on the configuration, the directory server could respond to the LDAP query with a list of every user in the directory services tree. You do not want an attacker to be able to see all the users in your tree.
An attacker could even use this field to view the attributes of a user object, such as the password.
An XML injection attack manipulates the XML structure used by an XML-based application or service. It inserts malicious content into the structure, which can affect the application's output. An XML injection attack might cause your CDATA field to be ignored by your XML parser and input validation filters. It will slip by. In this example, the payload contains a malicious URL. If the user clicks on the link thinking it's for something else, it will actually go to that user's banking account and run a cross-site request forgery attack. This is just a simple example, and the result of the attack would depend on what the malicious URL contains.
Let's review command-injection attacks. The purpose of this attack is to inject and execute commands in a vulnerable application. The vulnerable application runs commands on behalf of the attacker with the privileges assigned to the application itself.
Let's suppose a Linux server is running the DNS service. If an attacker was able to exploit this service, they could then run commands on this Linux server. This was a very popular attack several years ago. Many system administrators ran this service as the root user account, which allowed them to run commands with full access. To combat this attack, you should never run a service as an administrative user. Instead, create a limited user account on the system that only has access to what the service requires and nothing more.

Let's look at one more variation of the injection attack called the directory traversal attack or path traversal attack. This attack's goal is to gain access to a specific file stored elsewhere in the file system. It usually exploits some type of vulnerability in the application itself, such as not properly validating user input. In this case, characters representing the path to the parent directory on the application server could be manipulated to allow access to secure files.
For example, let's say there is a file directory with two subdirectories. Inside subdirectory A, there is a file named 123. Inside subdirectory B, there is a file named 456. The user, in this case, only has access to file 456, and he can search the directory hierarchy for a vulnerability and access file 123.
Because of this vulnerability, web applications need to be coded such that they look for all characters that could be used for directory traversal, whether it's the actual characters ("..", "/", "\") or their percent encoded equivalents.
In this lesson, we looked at injection attacks. We have covered LDAP, XML, and command injection attacks. We ended by looking at directory traversal attacks.

8.8.4 Zero Day Application Attacks (Lesson Video)

Transcript:

Let's talk about the Zero-Day Attack.

A zero-day attack is a threat that exploits a vulnerability in a computer application that is still unknown, or that has never been exploited before. There are two primary vehicles used to conduct these types of attacks.
The first one is a web browser. Browsers are popular targets because almost every system has one.
The other type is sending zero-day exploits via email. A zero-day email contains a link that launches the attack if it's clicked.
A zero-day attack occurs during the window between the time when the attacker first exploits the vulnerability and when the software developer creates a fix for it. This window may vary from a couple of days to many years.
With this in mind, let's look at a process that many software developers use to prevent zero-day attacks. It is the Unknown Vulnerability Management Process
The unknown vulnerability management process is a quality assurance process that finds and fixes unknown zero-day vulnerabilities. It is composed of four phases: analyze, test, report, and mitigate.
During the Analyze phase, the developers are trying to find the application's vulnerabilities. They're looking for weaknesses and attack vectors, which are ways an attacker can get into the application. Here, the developers try to break the application themselves.
Next is the Test phase. During this phase, what's called fuzz testing conducted against the attack vectors identified during the analysis phase.
After testing comes the Report phase. During the report phase, personnel try to reproduce any issues found during the testing phase to make sure that the situation is replicable and represents a real vulnerability.
Next is the Mitigate phase. This is where a fix is developed for the vulnerability, based on the results of the testing and reporting phases.
What should Security Administrators do to defend against zero-day attacks? First is to configure automatic updates for the operating system and the application.
By configuring automatic updates to the operating system, you are patching holes in the operating system where the application is running. The zero-day attacker is going to be looking for an exploit unique to that application. However, you want to close as many attack vectors as you can. Keeping your operating system updated will make your system safer from attacks in general.
You should also have a network firewall and a host firewall. By using a host-based firewall, you're hardening the system where the application is running, making it more difficult for an exploit to take place.
Finally, you should use an IDS or an IPS. For zero-day attacks, you are looking for anomalies. Consequently, virus scanners or malware detection applications probably won't work because they're based on signatures. There won't be a signature for an unknown exploit, and the attack will slip by your malware detection software.
By using an intrusion detection system or an intrusion prevention system, you look for anomalies against the norm. The IDS system will alert you that there is something unusual going on with the system. You can then begin troubleshooting, and you may discover a potential zero-day attack occurring.
In this video, we covered the basics of zero-day attacks and what they are. Then we looked at the methodology and procedures that software developers use to find the unknown vulnerabilities. Finally, we looked at a few things that you can do on your end to defend against zero-day attacks.

8.8.5 Web Browser Security Facts

This lesson covers the following topics:

- Manage browser data
- Enhance browser privacy

Manage Browser Data

A *web browser* is an application for retrieving and displaying information on the internet. Web browsers present the possibility of security breaches in an organization's network. There are general actions and browser-specific actions you can take to help harden the network against attacks from the internet.

When using a browser, the following might indicate an unsecured connection or an attack.

- A web document with a URL that contains a new or different domain name than the site you intended to visit.
- A menu bar that includes new commands or is missing common commands.
- The status line of the browser displays an unlocked symbol when SSL should be in use.

Regardless of the browser you are using, clear your private data regularly. Private data can be cleared based on the data's age. You can clear data from the last few hours, the last few weeks, or all the time. The type of browser you are using, and the types of sites you have visited will determine the type of data that can be cleared. Most browsers let you clear the following data:

- Browsing history
- Download history
- Cookies and other site data
- Cached images and files
- Passwords
- Auto-fill form data
- Site permissions
- Hosted app data

The following table lists steps for each browser to clear data.

Browser	Steps
Google Chrome	Steps for the Google Chrome browser are:

	Select the ellipses (three dots) button on the menu bar. Go to History > History. Select **Clear browsing data** .
Microsoft Edge	Steps for the Microsoft Edge browser are: Select the ellipses (three dots) button on the menu bar. Go to History. Select **Clear Browsing Data.**
Internet Explorer	Steps for the Internet Explorer browser are Select the Tools (gear) icon from the menu bar. Select Internet Options. Go to Browsing history. Select **Delete** .

Enhance Browser Privacy

You can use the following browser settings and guidelines to enhance browsing privacy and security. These may be named and implemented differently in different browsers, but the general ideas are the same.

Settings	Description
Cookies	*Cookies* are text files that save information about preferences, browser settings, and web page preferences. They identify you (or your browser) to websites. Be aware of the following facts about cookies: Cookies aren't inherently malicious and are often necessary for e-commerce websites. The use of cookies can constitute a privacy violation because cookies can retain personal information. A hacker could gain access to this information. Cookies can be misused by malware to collect and report your web surfing activities. *First-party cookies* are cookies used by the site you are visiting.

	Third-party cookies are cookies placed by sites linked to the site you are visiting. For example, banner ads on a website might place cookies on the machine to identify ads already seen or ads opened. Secured environments should restrict the use of cookies on all web browsers and other internet service utilities. Cookies can usually be found in the user profile in the file system.
Cache	A *cache* is a storage location for information that will be used again, such as images, sounds, web pages, and even usernames and passwords used on websites. In addition to taking up space, data in the cache could be retrieved by someone with access to the computer. To provide some level of protection, you should clear the web browser cache whenever you use a public computer to access the internet, especially when you have accessed sites for retrieving personal data.
Security	Enable the following options to increase security: Warn me when sites try to install add-ons. Block reported attack sites. Block reported web forgeries. It is best practice always to enter passwords and not to have the browser remember them. Do not select the **Remember passwords for sites** option. Do not select the **Use a master password** option. When you select this option, all passwords saved on the system are encrypted. You create a master password that retrieves and unencrypts passwords for individual sites.
Add-ons	An *add-on* , also known as a *plug-in* or *browser extension* , is a program that adds functionality and features to a web browser, including extra toolbars and interactive web content. Over time, a browser collects add-ons, some of which could have malicious intent. Secure the browser by reviewing add-ons and uninstalling items that are not appropriate for the environment. *Disabling* an add-on disables it for the current user. This allows users to enable or disable add-ons based on their own needs. *Deleting* an add-on removes it from the system and prevents any user from using it.
General	General information for web browser security includes: Use the **Always ask me where to save files** option to avoid having files downloaded without your knowledge. By using this option, you will always know when a file is being downloaded to the system. Enable the **Block Pop-up windows** option. Turn off **Remember search and form history** . Data you enter into forms, such as your banking account number, will be stored if this option is on.

	Turn off **Accept third-party cookies** or accept cookies and specify **ask me every time** so you will know when third-party cookies are created.

8.8.6 Clear the Browser Cache (Simulation)

Scenario

You use Google Chrome as your web browser on the desktop computer in your dorm room. You are concerned about privacy and security while surfing the web. You are also concerned about exploits that harvest data from your Google Chrome browsing history.

In this lab, your task is to delete the following items from your Google Chrome browser history for all time:

- Browsing history
- Download history
- Cookies and other site data
- Cached images and files
- Hosted app data

Explanation

Complete this lab as follows:

1. Delete all items from your Google Chrome history.
   1. From the Windows taskbar, select **Google Chrome** .
   2. In the upper right, select the **ellipsis** (three dots) and then select **History** > **History** .
   3. Maximize the window for better viewing.
   4. Select **Clear browsing data** .
   5. Select **Advanced** .
   6. For the Time range field, use the drop-down menu to select **All time** .
   7. Make sure the following items are checked:
      - Browsing history
      - Download history
      - Cookies and other site data

Cached images and files

Hosted app data

Select **Clear data** .

8.8.7 Preventing Cross-Site Scripting (Demo Video)

Transcript:

In this demonstration, we'll explore the steps you can take to safeguard yourself against cross-site scripting attacks, commonly known as XSS attacks. Although XSS attacks can exploit various web technologies like HTML and Flash, JavaScript is one of their primary vehicles. Consequently, we'll focus on how to disable JavaScript in Microsoft Edge and Google Chrome.

Before we delve deeper into this demo, please be aware that you can indeed prevent cross-site scripting attacks by disabling JavaScript in web browsers such as Microsoft Edge and Google Chrome. However, it's crucial to understand that disabling JavaScript can significantly impact the functionality and user experience of many websites. Please consider this trade-off carefully before implementing such restrictions.
Let's begin with Microsoft Edge. I've already opened Edge, and now we'll navigate to the settings. Click on the three dots, also known as the ellipsis, and select Settings.
In the settings menu, go to Cookies and site permissions. You'll find a list of items on the right. Scroll down until you locate JavaScript. Here, you can toggle off the switch next to Allowed (recommended) to disable JavaScript. In some versions of Edge, you might receive a confirmation dialog; if so, click Turn off to confirm the action. JavaScript is now disabled in Microsoft Edge. To enable it again, simply follow the same steps and toggle the switch back on.
Let's switch to Google Chrome and see how to disable JavaScript there. Click on the three dots in the top right corner, then select Settings. Navigate to Privacy and security and click on Site settings. Scroll down until you find JavaScript, and click on it. Choose the radio button that says, Don't allow sites to use JavaScript to disable it. To enable JavaScript, simply select Sites can use JavaScript to turn it back on.
It's also essential to mention the potential risks associated with the browser's credential autofill feature. This feature is often enabled by default in most commonly used browsers. To disable the ability to save passwords, go to Autofill and passwords and click on it. If you use Google Password Manager, you can toggle off Google's offer to save passwords and the ability to sign in automatically. Remember that these settings can be adjusted as needed.
In summary, the most effective prevention of cross-site scripting is typically implemented in the design of web applications. However, as a user, you may not always know if the sites you visit have taken all necessary precautions to protect against XSS attacks. Therefore, being able to disable JavaScript in your browser can provide an additional layer of security when needed. Just remember to weigh the potential loss of website functionality against the security benefits when deciding to disable JavaScript.

8.8.8 SQL Injections (Lesson Video)

Transcript:

SQL injection attacks are powerful and complex. They're the tool behind many successful high-profile internet security breaches.

In 2011, Sony was targeted by an SQL injection attack that compromised over a million emails, usernames, and passwords. In 2013, the United Stated Department of Energy was targeted, and at least 100,000 employee records were compromised. These records included contact information, social security numbers, and even bank account numbers. Perhaps the most ironic attack occurred when mysql.com was attacked, releasing a large list of usernames and passwords to hackers. In each of these instances, the vulnerability wasn't in the SQL software, but in the way the websites and applications were implemented. Each of these attacks could have been prevented with careful front-end configuration and penetration testing.

Because the SQL injection attacks target web applications, let's review how they work. When a user connects to a web application, they make a request through the browser. This request travels over the internet and to the web server. The web server accepts the request and sends it to the corresponding web app.
The web application accesses the database, completes the requested task, and then responds to the web server. Once the transaction is complete, the web server sends the requested information to the user's browser.
Because attackers are seeking information stored in the database, we also need to review how those work. Databases store all sorts of information, including application data, configuration data, customer data, login information, and--well--the possibilities are endless, so you can imagine why databases are valuable targets.
A database is typically described by the way it stores data. A relational database can be organized in different ways, depending on need. For example, customer orders can be sorted by customer number, zip code, or product number. A distributed database is designed so it's easy to replicate to various locations across a network. An object-oriented database is designed around object classes and sub-classes.
Inside these databases are various methods used to organize, manage, and retrieve data. Records and rows are used to represent a collection of relative data, such as information about a product, a user, or a customer. Think about the times you've gone shopping online, and you've sorted your selection by color, cost, or rating. These filters are possible because of these databases. When you think about the number of times you've entered contact information, account information, or other personal information, you can start to understand how valuable these stores of data are.
SQL was specifically designed to request data from a database. These requests take the form of a query--a question--that asks the database to provide information specific to your request.
It's important to note that SQL injections are a result of flaws in web applications, not in the database or the web server. These attacks exploit non-validated input vulnerabilities and use them to send SQL commands through the web application and to the database. This is done by injecting a code into an existing line of code before sending it onto the database for execution. If the injection is successful, the malicious code runs on the backend database and returns the requested information.
So, how does an SQL injection work? Let's start with a very basic example.
Let's say you're logging into your account. Normally, the user will enter their username-bobsmith--and their password-secret--into the appropriate spaces. Once they click Submit, the web application will send a string to the web server that contains the credentials.
The command tells the database to check for the provided username and compare it to the stored password before granting access. Assuming that the user is found, they're directed to the requested page. As you can see, the data that the user entered is put into the same query as the commands. As a result, this code is susceptible to SQL injection attacks. If the login fields haven't been restricted, an attacker can add anything they want to them.
Let's say the attacker knows that Bob's username is bobsmith, but they don't know Bob's password. They may be able to enter 'bobsmith'--'in the username field. The single quote indicates that data has ended and a command is beginning. The double dashes indicate that code is ending and a comment is being entered. Comments are code that a program doesn't execute--they usually contain explanations or reminders for the programmer. Because of this, the application knows to ignore the comments.
Now, because the command treats everything after the dashes as comments, the instruction to verify the username with a given password is no longer visible, and the user is granted access to the user account.
Although it's fairly easy to detect the initial vulnerabilities for this attack, SQL injections are extremely complex. They require a lot of patience and a high level of database and coding expertise. So, why would attackers go to all this trouble? Well, with great effort comes great reward, and that's what these attackers are counting on. SQL injections can be used to implement several types of attacks.
When an attacker attempts an authentication bypass, they log into an application with administrative privileges without having to give a valid username or password. An information disclosure attack provides an attacker with sensitive information from the database. An attacker can use a compromised data integrity attack to deface a web page or alter a database's contents. Attackers can use an SQL injection attack to compromise data's availability; in other words, they can use it to delete information stored in the database. Attackers can also use this type of attack to remotely execute code and compromise the host operating system.
Well, that's all for this lesson. We talked about SQL injections and how they relate to web application and database technologies.

8.8.9 Exploit SQL on a Web Page (Demo Video)

Transcript:

The internet used to be pretty simple and straightforward. There was no JavaScript, Flash, CSS, backend databases, or, really, any complex web design technologies. That's all changed, and it's changing more rapidly than ever. These days, most websites are dynamic and database-driven. Site content is dependent on user input most of the time, and that data is written to a database, typically an SQL database. Like every other piece of computing technology that's invented to solve a problem, hackers have figured out how to attack these databases.

The term for attacking an SQL database is an SQL injection. It's a very common way to attack databases. The Open Web Application Security Project, OWASP, almost always includes weak SQL databases in their list of the top ten most widely exploited vulnerabilities.
In this demo, we're going to cover a few SQL injections on a vulnerable web page. This isn't a demo on SQL in general. We're just taking a quick look at some things to be aware of as a penetration tester or ethical hacker.
I'm on a Windows 10 system. I've already done a few things to it. First, I've downloaded and installed XAMPP, which is a package that contains Apache, Maria Data Base, PHP, and Perl. I've also downloaded and configured the Darn Vulnerable Web Application, DVWA, which is a vulnerable PHP and MySQL web application designed for security professionals to practice their penetration testing and ethical hacking skills.
First, we want to do a few simple injections. Let's start out by typing in a number, number 1. Click Submit. Now let's type in 2 and click Submit. All this does is give you the user ID, first name, and surname. That's not very useful, but it does show that it's not designed very well. We want to get more than that, so let's expand on our SQL injection.
We're going to enter code to pull up records for a specific user. By crafting our input, we can get more from the output than the code author intended. So, let's enter in the number 1, which is the user ID, with a single quote followed by a true statement. Our true statement can be anything that's true, such as 1 is equal to 1. It will look like this: â€˜1' and 1=1#'. Click Submit. We see the first name and the surname for that user.
Now let's go a little further. Let's say we want to find out our database name and username for the database. For that, I'll do a select statement by entering in â€˜1' and 1=1 union select database(), user()#'and press Enter. Now, down here, I get the name of my database, which is dvwa, and the username is root@localhost.
I want to see if I can get a list of tables from our database. For that, I'll do another select statement and enter in â€˜1' and 1= union select null, table_name from information_schema.tables#' and press Submit. Okay. I just got a long list of tables here. I'm looking for something that might have a list of usernames and passwords in it. Right here, I see a table called users, so I wonder if that might be the list of users along with their passwords? There's one way to find out: let's see if we can pull information from that table.
To pull the information out of the Users table, I'll enter in the following select statement: â€˜1' and 1= union select user password from users#' and click Submit. Here, you can see a nice list of the usernames along with the password hashes for each one. Now we can use a cracking program to attempt to crack any of these hashes.
And that's it for this demo. In this demo, we used a vulnerable website to practice some SQL injections. First, we found a list of users. Then we expanded to find the name of the database and the username. We ended by finding a list of tables, specifically the user table, and then retrieved the usernames and password hashes from that table.

8.8.10 Web Application Attack Facts

People today connect, learn, shop, provide services and information, and do business over the internet. All of this is made possible through web browsers and web applications. There are literally thousands of applications that are used in our everyday lives. With so many options, there are many ways that attackers have found to exploit them.

This lesson covers the following topics:

- Privilege escalation
- Pointer/object dereference
- Buffer overflows
- Resource exhaustion
- Memory leak

Race conditions

Error handling

Improper input handling

Replay attacks

Pass the hash

Application programming interface (API) attacks

Secure Sockets Layer (SSL) stripping

Driver manipulation

Privilege Escalation

Most attacks are some form of privilege escalation. There are two types:

Horizontal

This is when an attacker gains data that belongs to another user with the same privilege level as themselves (like a co-worker).

Vertical

This is when an attacker uses a system's vulnerabilities to escalate privileges to gain administrative access.

Pointer/Object Dereference

Dereferencing a pointer is retrieving the value stored in memory.

Some important facts:

A pointer stores a memory address.

All operating systems embed the kernel in the user's workspace.

The kernel is the operating system's core program that controls everything in the system.

Page protections protect the kernel from user access but can be exploited by a DoS attack through a NULL pointer dereference.

If a DMA driver module does not have enough security protections in place, it can release user pages that are pinned to a pointer with a NULL value. This happens when:

An app dereferences an object that comes back NULL instead of valid.

Null is exploited as a constant built in to evaluate to 0 in the C language.

An x86 system has a valid 0 address in the kernel address space.

Buffer Overflows

Buffer overflow important facts:

- A buffer is a temporary data storage area with limited space.
- Overflows occur when more data is attempting to be stored than the program was written for.
- Can allow hackers to cause data to flow to other memory areas that may not be protected.
  - Attackers may now access database files or system files and can replace executable code with malicious code. This is called arbitrary code execution.
- It can cause DoS attacks by crashing the program.
  - IT can occur in routers, IoT devices, and firewalls.

Resource Exhaustion

Resource exhaustion is a form of attack that focuses on depleting the resources of a network to create a denial of service to legitimate users.

This attack can be done through:

- Slow header attacks:
  - Send HTTP headers so slowly that it prevents other users from accessing the site.
  - Can be prevented with HTTP header timeouts.
- Slow post attacks:
  - Send HTTP POST body very slowly. This is done through forms, logins, and feedback input fields.
  - Can be prevented by setting a maximum body size for each form and setting the web server setting with a max total transfer time.

Resource exhaustion attacks can be focused on memory, file system storage, database connection pool entries, or the CPU. When an allocation of these resources is requested, but the size of the resource or number is not controlled, a denial of service results from a lack of resources.

Memory Leak

A memory leak happens when dynamic memory is allocated in a program, but no pointers are connected to it. This causes it never to be returned when requested.

- Programmers often create temporary memory allocations. This becomes a problem when they are not deleted after use.

Whether unintentionally leftover from a project or intentionally created by an attacker, memory leaks can result in:

- Resource exhaustion.
- DoS.
- Exploitation of other areas affected by low-memory conditions.

To mitigate these attacks:

- Delete unneeded memory allocations when finished with a project.
- Ensure that pointers are properly connected to memory values.

Race Conditions

Another web application vulnerability is a time-of-check to time-of-use bug, or (TOCTTOU) bug. This happens when a system is programmed to run with certain processes dependent on a sequence of events or race conditions.

It can happen when an attacker schedules an execution of operation between a time of check and a time of use and forces the user's process to pause or send an error. For example, in the moment between authenticating to a system and utilizing the system, the attacker can jump into the process and act as the authenticated user, leading to privilege escalation.

To mitigate:

- Ensure your operating system's file system state is not allowed to change between two system calls.
- Use file system calls that run on file handles instead of file names when possible.
- Lock single files before the check.

Error Handling

Improper error handling can create vulnerabilities in a system by revealing information that attackers can use to exploit the system. This display of too much information can result from coding practices that are not in alignment with security policies. Some examples are:

- An attacker may use a SQL injection attack that fails initially. However, the error message discloses the malformed query, which could show the query logic or other sensitive data, like passwords. The attacker can use the new information from the error message to gain access to the system.
- The disclosure of the full pathname in an error message generated from a path-traversal weakness exploit attempt.

To mitigate, be sure to program the error message with minimal information that's only useful to the intended audience.

Improper Input Handling

Improper input handling refers to a lack of validation, sanitization, filtering, decoding input data, or encoding input data.

Processing of untrustworthy input data can lead to:

- Buffer overflows.
- XSS.
- Directory traversal.
- NULL byte injections.
- SQL injection.
- Uncontrolled format string.
- DoS.
- OS commanding.

To mitigate:

- Set specific parameters for acceptable data forms and types.
- Accurately define data restrictions.
- Sanitizing, validating, and filtering properly.

Replay Attack

Replay attacks happen when network traffic is intercepted by an unauthorized person who then delays or replays the communication to its original receiver, acting as the original sender. The original sender is unaware of this occurrence.

- Also known as session replay attacks
- They are a type of man-in-the-middle attack

To mitigate, implement:

- Strong digital signatures with timestamps.
- Session keys that are time-bound and process-bound.
- Sequence numbers.
- Program authentication systems to accept network packets that have valid timestamps and sequence numbers.

Pass the Hash

Pass the hash is dangerous to an organization because once an attacker gains access, the whole organization can be compromised very quickly.

How it works:

An attacker gains access to an individual computer through malware or other techniques.

The attacker accesses the memory in the workstation to find stored hashes of other users that have used the workstation.

The attacker uses the stored hashes to gain access to other workstations in search of a station that grants privilege escalation.

To mitigate:

Use direct networking to prevent standard users and local admin users from having access to other user's workstations.

Use Group Policy Object (GPO) Editor to disable Remote Desktop Connections in an Active Directory network.

Limit domain admins' access to only workstations with the same level of privileges.

Create separate standard user-level accounts for admins when accessing lower-level privilege machines.

Application Programming Interface (API) Attacks

Application programming interfaces (APIs) are how businesses transfer information between systems within their organization or how a business communicates information to another organization. This is also a means of information transfer between companies and their customers, as APIs are the way most applications communicate with websites.

Many APIs are openly published to promote customer usage and make interactions easy. However, they do create an opportunity for a malicious user to exploit the interface to gain access to internal data and infrastructure. For example, an e-commerce site may use its API for product catalog pages on its website, in its mobile app, for a third-party reseller, and for search engine bots that bring customers to its website.

To mitigate potential API problems:

Implement rate limiting. This limits the number of calls from a client within a time limit.

Use security logs to detect and analyze unauthorized access attempts.

Look for SQL injections. These happen when a SQL statement is entered in a data field and gets executed in the database.

Make sure that program notifications are sent when there is an excess of error messages.

Secure Sockets Layer (SSL) Stripping

SSL stripping is an attack that focuses on stripping the security from HTTPS-enabled websites. This is how it works:

An attacker intercepts the initial request a user sends to a website.

The attacker establishes a secure connection with the intended server and an insecure HTTP connection with the user where all communication goes through them.

The attacker can intercept the initial request when it comes through a 302 redirect or through a non-SSL site that provides a link to a proxy that looks like the intended site.

To mitigate:

Encrypt all elements of your site with an SSL certificate.

Add your domain to the HSTS preload list. This lets browsers know that your site is secure.

Driver Manipulation

A device driver is a small piece of software that provides an interface between the operating system and a hardware device, such as a printer, keyboard, or network card. Attackers can manipulate a driver by adding malicious logic. Driver manipulation attacks often happen as a result of a web application attack, such as a drive-by download or through social engineering or phishing. The goal is to replace a good driver with one that is malevolent or to add software that comes between a good driver and the operating system.

Common driver manipulation attacks include:

Attack	Description
Refactoring	Software or code refactoring is usually considered a beneficial practice. The external behavior of refactored software code does not change. Internally, the code is modified to improve readability, reduce complexity, or improve efficiency. Attackers refactor device drivers so that their external behavior does not change. The printer, keyboard, network card, or hardware controlled by the driver still functions properly. This makes it hard to detect any problems. Internally, the refactored driver now has hidden functions that benefit the attacker.
Shimming	Like refactoring, shimming is usually beneficial. As operating systems and other software libraries are updated, their application programming interface (API) may change. The API specifies how other programs should interact with the software library or operating system. If the API is updated with new specifications, other programs using older API specifications may not work. To remedy this, a shim can be used. A shim is software placed between the newer API and software that conforms to the older API. The shim intercepts calls to the older API, translates them, and passes them to the newer API. In some cases, they can redirect the API calls elsewhere to complete the expected operation called for in the older API. Attackers can modify existing shims by injecting malicious code. They can also create a shim that intercepts valid API calls. However, the shim executes malicious code before it passes the valid calls through to the API.

To mitigate:

Use the latest browser version and patch level.

Verify that the operating system is at the latest patch level.

Install antivirus, anti-spyware, pop-up blocking, and firewall software.

Use input validation when programming services.

Client-side validation should first be used on the local system to identify input errors before the data is ever sent to the server.

For example, if the user enters an invalid value in an email address field, the error can be detected before the data is submitted.

Server-side validation should be used for error detection after the data is sent to the server. Experienced attackers can circumvent client-side validation techniques to send malicious information to the server.

For example, an attacker could send data to the server from outside the application's standard user interface, bypassing any input validation measures that may have been implemented on the client. It is unwise to rely solely on client-side input validation techniques.

Implement DNS Security Extensions, or DNSSEC. This is a security measure that only allows connection to your computer from servers that have previously been given a digital certificate.

Use HTTPS. This transfer protocol encrypts the HTTP over Transport Layer Security (TLS) or over Secure Socket Layer (SSL), protecting your browser against threats.

Use add-ons to increase the security of browsing activities:

NoScript blocks all active content except from sites you trust.

Adblock Plus blocks advertisements and ad banners (which could contain malicious code) on the internet.

Train users to log out of websites when finished. Users should never allow applications to remember their authentication information.

8.8.11 Perform an SQL Injection Attack (Simulation)

Scenario

Your name is Blake Jackson. You are the penetration tester for a small corporate network. After performing several SQL injection attract tests on the corporate network, you have decided to see how secure your own online bank's web page is.

In this lab, your task is to perform a simple SQL injection attack using the following information:

Your bank's URL: **MySecureOnlineBank.com**

Make an account query using your account number: **90342**

Answer Question 1.

Perform a simple SQL attack using: **0 OR 1=1**

Use the entire statement of " **0 OR 1=1** " but without quotes.

Answer Question 2.

Explanation

Complete this lab as follows:

Look up Blake Jackson's account balance.

From the taskbar, select **Google Chrome** .

Maximize the window for better viewing.

In the URL field, type **mysecureonlinebank.com** and then press **Enter** .

In the *Enter your Account Number* field, enter **90342** .

Select **Lookup** .

From the top right, select **Answer Questions** .

Answer Question 1.

Minimize the **Answer Questions** window.

Perform a simple SQL attack.

In the *Enter your Account Number* field, enter **0 OR 1=1** for the SQL injection.

Select **Lookup** .

From the top right, select **Answer Questions** .

Answer Question 2.

Select **Score Lab** .

8.8.12 Practice Questions (Section Quiz)

q_browser_sec_add-on_secp8

You are a cybersecurity consultant hired by a company that has recently experienced a data breach.

After an initial investigation, you discover that the breach originated from a compromised workstation where the user frequently used a web browser with multiple add-ons.

What is the most effective action to take to enhance browser privacy and prevent future breaches?

Answers:

Clear the web browser cache

Disable all browser add-ons

***Review and uninstall inappropriate add-ons**

Turn off Remember search and form history

Explanation:

Reviewing and uninstalling inappropriate add-ons is the correct answer. By reviewing and uninstalling inappropriate or potentially malicious add-ons, you can directly address the source of the problem and enhance the browser's security and privacy.

While clearing the web browser cache can help to remove stored information such as usernames, passwords, and web pages that have been visited, it does not address the issue of potentially malicious add-ons that could compromise the browser's security.

Disabling all browser add-ons can prevent potentially malicious add-ons from running, but it may also disable useful and safe add-ons. This approach is too broad and does not specifically target the source of the problem.

While turning off *Remember search and form history* can help to prevent the browser from storing data entered into forms, it does not address the issue of potentially malicious add-ons that could compromise the browser's security.

q_browser_sec_clear_data_secp8

As a cybersecurity expert, you are tasked with advising a company on best practices for managing browser data to maintain security and privacy.

Which of the following is the MOST crucial step to take?

Answers:

Regularly update the browser.

Use incognito mode for all browsing.

***Clear your private data regularly.**

Only visit HTTPS websites.

Explanation:

Clearing your private data regularly is the correct answer. Regularly clearing private data, such as browsing history, cookies, cached images, and files, can help prevent unauthorized access to this information and protect user privacy.

While keeping the browser updated is important to ensure that the latest security patches are applied, it does not directly manage the data the browser stores during use. Therefore, it is not the most crucial step.

Incognito mode prevents the browser from storing browsing history, cookies, and form data. However, it does not prevent third-party websites from tracking user activity during the session. Moreover, it does not manage data from non-incognito browsing sessions.

While visiting only HTTPS websites can help protect data during transmission by encrypting it, it does not manage the data the browser stores during use. Therefore, it is not the most crucial step.

q_browser_sec_clear_web_cache_secp8

You are the IT manager at a large corporation. One of your employees has been using a public computer to access the company's internal systems.

You notice that the employee has not been following best practices for enhancing browser privacy.

Which of the following actions would be the most effective in preventing unauthorized access to sensitive company data?

Answers:

Disabling all browser add-ons

Blocking all pop-up windows

***Clearing the web browser cache**

Turning off Remember search and form history

Explanation:

Clearing the web browser cache is the correct answer. The web browser cache can store information such as usernames, passwords, and web pages that have been visited. If this data is not cleared, someone with access to the computer could potentially retrieve this information and gain unauthorized access to sensitive company data.

While disabling all browser add-ons can help to enhance browser security by preventing potentially malicious add-ons from running, it does not directly prevent unauthorized access to sensitive company data that may have been stored in the browser cache.

Blocking all pop-up windows can help to prevent unwanted or potentially harmful pop-ups from appearing, but it does not directly prevent unauthorized access to sensitive company data that may have been stored in the browser cache.

While turning off *Remember search and form history* can help to prevent the browser from storing data entered into forms (such as banking account numbers), it does not directly prevent unauthorized access to sensitive company data that may have been stored in the browser cache.

q_browser_sec_files_download_secp8

As a cybersecurity expert, you are advising a company on best practices for general web browser security.

\Which of the following measures is MOST crucial to prevent unauthorized file downloads?

Answers:

Enable the Block Pop-up windows option.

Turn off Remember search and form history.

***Use the Always ask me where to save files option.**

Turn off Accept third-party cookies.

Explanation:

While blocking pop-up windows can help prevent unwanted or potentially harmful pop-ups from appearing, it does not directly prevent unauthorized file downloads.

While turning off *Remember search and form history* can help to prevent the browser from storing data entered into forms, it does not directly prevent unauthorized file downloads.

Using the *Always ask me where to save files* option is the correct answer. By using this option, users will always be aware when a file is being downloaded to the system, which can help prevent unauthorized or unexpected file downloads.

While turning off *Accept third-party cookies* can help to prevent third-party websites from tracking user activity, it does not directly prevent unauthorized file downloads.

q_browser_sec_web_cookies_secp8

You are a cybersecurity analyst at a large corporation. One of your responsibilities is to ensure that employees are following best practices for enhancing browser privacy.

You notice that one department is experiencing a higher than usual number of security incidents related to their web browsing habits.

What is the MOST effective action to take to enhance browser privacy and reduce these incidents?

Answers:

Enforce the use of incognito mode.

***Restrict the use of cookies.**

Clear the web browser cache regularly.

Disable all browser add-ons.

Explanation:

Restricting the use of cookies is the correct answer. Cookies are text files that save information about preferences, browser settings, and web page preferences. They can be used by websites to track user activity and can potentially be misused by hackers to collect and report your web surfing activities. Restricting the use of cookies can significantly enhance browser privacy and reduce security incidents.

While using incognito mode can help to prevent the browser from storing browsing history, cookies, and form data, it does not prevent third-party websites from tracking user activity during the session. Moreover, it does not manage data from non-incognito browsing sessions.

While clearing the web browser cache can help to remove stored information such as usernames, passwords, and web pages that have been visited, it does not address the issue of cookies, which can track user activity and potentially be misused by hackers.

Disabling all browser add-ons can prevent potentially malicious add-ons from running, but it may also disable useful and safe add-ons. This approach does not specifically target the issue of cookies, which can track user activity and potentially be misused by hackers.

q_webattk_app_attack_secp8

You are a security analyst at a tech company. You notice a significant increase in the number of failed login attempts on the company's web application. You suspect that the application might be under an application attack.

Which of the following actions should you take next?

Answers:

Ignore the failed login attempts as they are likely due to users forgetting their passwords.

***Implement a CAPTCHA system to prevent automated login attempts.**

Advise users to change their passwords immediately.

Shut down the web application until the issue is resolved.

Explanation:

Implementing a CAPTCHA system can help prevent automated login attempts, which are common in application attacks, and is the correct answer. This can help protect the application from being compromised.

Ignoring the failed login attempts could potentially allow an attacker to compromise the security of the website or web application. It's important to investigate unusual activity to ensure the security of the application.

While advising users to change their passwords can be a good security measure, it may not prevent an application attack. If the attack is automated, changing passwords will not stop the attack.

While shutting down the web application could stop the attack, it is not a practical solution. It would disrupt service for all users and may not address the underlying security issue.

q_webattk_buffer_01_secp8

Which of the following attacks is a form of software exploitation that transmits or submits a longer stream of data than the input variable is designed to handle?

Answers:

Time-of-check to time-of-use attack

Data diddling

Smurf attack

***Buffer overflow attack**

Explanation:

A buffer overflow occurs when software code receives more input than it was designed to handle. This normally occurs because the programmer of that code failed to include input validation checks. When a buffer overflow occurs, the extra data is pushed into the execution stack and processed with the security context of the system itself. In other words, a buffer overflow attack often allows the attacker to perform any operation on a system.

A time-of-check to time-of-use (TOCTOU) attack occurs when the results of an attack are realized or initiated after the attack itself is perpetrated.

Data diddling is the purposeful altering of data.

A smurf attack is a form of distributed-reflective denial of service.

q_webattk_buffer_02_secp8

A programmer that fails to check the length of input before processing leaves his code vulnerable to which form of common attack?

Answers:

Backdoor

Session hijacking

***Buffer overflow attack**

Privilege escalation

Explanation:

Buffer overflow attacks are made possible by the oversight of programmers. A simple check on the length (and sometimes format) of input data before processing eliminates buffer overflow attacks.

A backdoor is a developer-planted or cracker-planted entry device that bypasses security to gain access to a system or software. A developer-planted backdoor is often a debugging tool mistakenly left in place when the software went to market. A cracker-planted device is often a remote access server that listens for inbound connections on a specific port. Either method can be used by an intruder to gain entry into a secured environment.

Session hijacking is the concept of being able to take over a communication session between a client and server. This usually involves taking over the identity of the client and fooling the server into communicating with the pseudo-client.

Privilege escalation is the act of a user stealing or obtaining higher-level privileges in a computer system.

q_webattk_buffer_03_secp8

Having poor software development practices and failing to program input validation checks during development of custom software can result in a system vulnerable to which type of attack?

Answers:

***Buffer overflow attack**

Denial-of-service attack

Dictionary attack

Superzapping

Explanation:

Poor software development practices and failing to program input validation checks can leave a system vulnerable to buffer overflow attacks. A buffer overflow occurs when software code receives more input than it was designed to handle because the programmer of that code failed to include input validation checks. When a buffer overflow occurs, the extra data is pushed into the execution stack and processed with the security context of the system itself. In other words, a buffer overflow attack often allows the attacker to perform any operation on a system.

Denial-of-service attacks exploit vulnerabilities in implementation and coding errors.

Dictionary attacks are waged against logon prompts or stolen copies of a security account's database.

Superzapping attacks are specific attacks that use a specialized utility named superzap to bypass the security of IBM mainframes to perform system alterations.

q_webattk_buffer_04_secp8

Which type of attack is the act of exploiting a software program's free acceptance of input in order to execute arbitrary code on a target?

Answers:

Data diddling

***Buffer overflow attack**

TOCTOU

Covert channel exploitation

Explanation:

The act of exploiting a software program's free acceptance of input in order to execute arbitrary code on a target is called a buffer overflow.

Data diddling is the change or corruption of data.

TOC/TOU is a logon session replay attack.

Covert channel exploitation is the use of timing or storage mechanisms to bypass security controls in order to leak information out of a secured environment.

q_webattk_buffer_05_secp8

A software development company pushes a critical update for its operating system, addressing security vulnerabilities.

The chief information security officer (CISO) schedules a meeting with the security team to discuss the specifics of one of these vulnerabilities exploited in recent cyberattacks.

Based on common operating system vulnerabilities, which of the following has insufficient or missing data validation mechanisms that lead to the system interpreting unintended command execution?

Answers:

***Buffer overflow**

Privilege escalation

Side-channel attack

Fingerprinting

Explanation:

Buffer overflow vulnerabilities occur when an application receives more data than it can handle, resulting in the potential for unintended command execution.

Privilege escalation refers to an attacker gaining unauthorized privileges on a system, usually through exploiting system misconfigurations or vulnerabilities that allow them to elevate their permissions.

Side-channel attacks are techniques that gather information indirectly from the physical implementation of a computer system rather than from software vulnerabilities or direct intrusion attempts.

Fingerprinting is the method used to determine the operating system running on a remote host, which does not involve exploiting a specific vulnerability within the operating system.

q_webattk_buffer_06_secp8

An organization experienced disruptions in its business operations due to repeated crashes of a critical application.

The IT department suspects a security issue and initiates a thorough investigation. The findings suggest the application failed due to excessive data processing beyond its expected limits.

What does the IT department confirm is the cybersecurity threat occurring in its business operations?

Answers:

***Buffer overflow attack**

Distributed denial-of-service (DDoS) attack

On-path attack

Social engineering attack

Explanation:

Buffer overflow attacks occur when an application receives more data than it can process, which can cause the application to crash or allow an attacker to execute arbitrary code. This is consistent with the symptoms described in the scenario.

A DDoS attack overwhelms a system's resources with traffic but does not involve overflowing an application's buffer with excessive data.

An on-path attack involves an attacker intercepting and possibly altering the communication between two parties and does not align with the application crashes described.

Social engineering attacks manipulate people into divulging confidential information. They do not involve direct attacks on an application's memory or cause application crashes.

q_webattk_buffer_07_secp8

An attacker passes data that deliberately floods a temporary memory space on one of the corporate machines.

What type of application vulnerability does this action describe?

Answers:

***Buffer overflow**

Race conditions

Malicious update

Memory injection

Explanation:

To exploit a buffer overflow vulnerability, the attacker passes data that deliberately floods a temporary memory space.

Application race condition vulnerabilities refer to software flaws associated with the timing or order of events within a software program, which can cause undesirable or unpredictable outcomes through manipulation.

A malicious update is an update that appears legitimate but contains harmful code, often used by cybercriminals to distribute malware or execute a cyber attack.

Memory injection vulnerabilities refer to a security flaw where an attacker can introduce or inject malicious code into a running application's process memory.

q_webattk_canonicalization_attack_secp8

You are a security analyst at a large e-commerce company. During a routine security audit, you discover that the company's web application is vulnerable to a canonicalization attack. The application uses file paths provided by users to access and display files.

Which of the following actions should you recommend to mitigate this vulnerability?

Answers:

Implement SSL/TLS encryption for all data in transit.

***Implement a whitelist of approved file paths and reject any requests that do not match.**

Switch to a different programming language that is less susceptible to canonicalization attacks.

Disable all client-side scripting.

Explanation:

Implementing a whitelist of approved file paths and rejecting any requests that do not match is a key defense against canonicalization attacks and is the correct answer. This ensures that only approved paths can be accessed, preventing an attacker from accessing unauthorized files.

While SSL/TLS encryption is important for protecting data in transit, it does not prevent canonicalization attacks. Canonicalization attacks manipulate the interpretation of file paths or URLs, which can occur regardless of whether the data is encrypted.

Simply switching to a different programming language does not inherently make the application more secure. If the application does not properly handle file paths or URLs, it could still be vulnerable to canonicalization attacks regardless of the programming language used.

Disabling all client-side scripting would not prevent canonicalization attacks. Canonicalization attacks target the server-side processing of file paths or URLs, not client-side scripts.

q_webattk_cross_secp8

Which of the following is an attack that injects malicious scripts into web pages to redirect users to fake websites to gather personal information?

Answers:

***XSS**

SQL injection

DLL injection

Drive-by download

Explanation:

Cross-site scripting (XSS) is an attack that injects scripts into web pages. When a user views the web page, the malicious scripts run, allowing the attacker to capture information or perform other actions.

XSS often relies on social engineering or phishing to entice users to click on links to web pages that contain malicious scripts.

Some scripts redirect users to legitimate websites but run in the background to capture information sent to the legitimate site.

Scripts can be written to read (steal) cookies that contain identity information (such as session information).

Scripts can also be designed to run under the security context of the current user. For example, scripts might execute with full privileges on the local system, or the scripts might run using the credentials used on a financial website.

A drive-by download is an attack where software or malware is downloaded and installed without explicit consent from the user.

An SQL injection attack occurs when an attacker includes database commands within user data input fields on a form, and those commands subsequently execute on the server.

A DLL injection attack occurs when a program is forced to load a dynamic-link library (DLL). This DLL then executes under the security context of the running application and executes malicious code included with the injected DLL.

q_webattk_csrf_secp8

You are a security analyst for a large e-commerce company. You notice that a significant number of users are complaining about unauthorized transactions on their accounts.

After investigating, you suspect that the site might be a victim of a Cross-Site Request Forgery (CSRF) attack.

Which of the following actions should you take next?

Answers:

Ignore the complaints as false positives since the transactions are coming from the users' IP addresses.

Implement CAPTCHA on all transaction pages to prevent automated attacks.

***Implement a CSRF token in your web application's forms.**

Advise users to change their passwords immediately.

Explanation:

Implementing a CSRF token in your web application's forms is a common and effective defense against CSRF attacks and is the correct answer. The token is a random value associated with the user's session and is included in every form submission. If the token in the form doesn't match the token on the server, the request is rejected.

Ignoring the complaints is not advisable as CSRF attacks can be performed from the users' browsers, making it appear as if the transactions are coming from their IP addresses.

While CAPTCHA can help prevent automated attacks, it is ineffective against CSRF attacks. CSRF attacks involve tricking the user into submitting a request, so a CAPTCHA would not prevent this.

While advising users to change their passwords is generally a good security measure, it would

q_webattk_injection_secp8

A cybersecurity analyst is trying to discover why a web application's interpreter executes unintended commands. The analyst notices that the attack involves sending untrusted data to an interpreter as part of a command or query.

What does the analyst suspect is happening?

Answers:

***Injection attack**

Replay attack

On-path attack

DDoS attack

Explanation:

Injection attacks involve sending untrusted data to an interpreter as part of a command or query. This data tricks the interpreter into executing unintended commands, potentially allowing unauthorized access or data retrieval.

Replay attacks involve the malicious repetition or delayed transmission of valid data. This type of attack does not relate to manipulating interpreters with untrusted data.

An on-path attack occurs when an attacker intercepts and possibly modifies packets in transit. It does not involve sending untrusted data to an interpreter as part of a command or query.

Distributed denial-of-service (DDoS) attacks overwhelm systems with traffic, aiming to make them unavailable. These attacks do not involve sending untrusted data to an interpreter.

q_webattk_input_secp8

Which of the following is specifically meant to ensure that a program operates on clean, correct, and useful data?

Answers:

***Input validation**

Application hardening

Process spawning

Error and exception handling

Explanation:

Input validation is the process of ensuring that a program operates on clean, correct, and useful data. Input validation uses routines (also called validation rules or check routines) that check for correctness, meaningfulness, and secureness in data input to the system.

Application hardening is the process of preventing vulnerability exploitation in software applications.

Error and exception handling is a programming language construct designed to handle the occurrence of exceptions (which are special conditions that change the normal flow of program execution).

Process spawning is the creation of a new process (also called a child process) by an existing process (also called a parent process).

q_webattk_ldap_injection_secp8

You are a security engineer at a large corporation. During a routine security audit, you discover that the company's internal application is vulnerable to Lightweight Directory Access Protocol (LDAP) Injection attacks.

The application uses LDAP for user authentication and does not sanitize input when adding filter parameters.

Which of the following actions should you recommend to mitigate this vulnerability?

Answers:

Implement SSL/TLS encryption for all data in transit.

Switch to a different authentication protocol like OAuth.

***Implement proper input validation and sanitization.**

Disable all client-side scripting.

Explanation:

Implementing proper input validation and sanitization is a key defense against LDAP Injection attacks and is the correct answer. This includes validating and sanitizing all user inputs and also using techniques like parameterized queries or prepared statements to ensure that user input is not interpreted as code.

While SSL/TLS encryption is important for protecting data in transit, it does not prevent LDAP Injection attacks. LDAP Injection attacks manipulate the structure of LDAP queries, which can occur regardless of whether the data is encrypted.

Simply switching to a different authentication protocol like OAuth does not inherently make the application more secure. If the application does not properly sanitize input, it could still be vulnerable to other types of injection attacks.

Disabling all client-side scripting would not prevent LDAP Injection attacks. LDAP Injection attacks target the server-side processing of LDAP queries, not client-side scripts.

q_webattk_memory_injection_secp8

You are a software engineer developing a new application for a healthcare provider.

During a code review, you notice that the application is using unmanaged code and directly accessing memory addresses, which could potentially lead to memory injection attacks.

Which of the following actions should you take next?

Answers:

Continue with the current design, but implement strong input validation.

***Switch to a managed code language that handles memory management automatically.**

Implement a custom memory management system to prevent unauthorized access.

Use encryption for all data stored in memory.

Explanation:

Switching to a managed code language that handles memory management automatically can significantly reduce the risk of memory injection attacks and is the correct answer. Managed code languages like Java or C# provide built-in protections against direct memory access.

While strong input validation is a good security practice, it alone may not prevent memory injection attacks. Attackers can often craft malicious payloads that bypass common input validation techniques.

Implementing a custom memory management system can be complex and error-prone. It's generally better to rely on the memory management provided by modern programming languages, which have been extensively tested and refined.

While encryption can protect data at rest and in transit, it does not prevent memory injection attacks, which exploit the way an application accesses and manipulates memory.

q_webattk_privilege_escalation_secp8

You are a security engineer at a large corporation. During a routine security audit, you discover that the company's internal application allows users to view the profiles of other users by manipulating the URL. This could potentially lead to a privilege escalation attack.

Which type of privilege escalation is this, and what should you do to mitigate this vulnerability?

Answers:

This is a vertical privilege escalation. Implement role-based access control to prevent users from accessing higher-level privileges.

***This is a horizontal privilege escalation. Implement proper input validation and sanitization.**

This is a vertical privilege escalation. Implement proper input validation and sanitization.

This is a horizontal privilege escalation. Implement role-based access control to prevent users from accessing other users' profiles.

Explanation:

This is a horizontal privilege escalation, and implementing the proper input validation and sanitization is the correct answer. Horizontal privilege escalation involves accessing other users' profiles or data. Implementing proper input validation and sanitization can help prevent users from manipulating the URL to access other users' profiles.

Vertical privilege escalation involves elevating a user's privileges to a higher level, not accessing other users' profiles. Implementing role-based access control is a good security measure, but it may not prevent horizontal privilege escalation.

Vertical privilege escalation involves elevating a user's privileges to a higher level, not accessing other users' profiles. Implementing proper input validation and sanitization is a good security measure, but it does not address the type of privilege escalation in question.

While implementing role-based access control is a good security measure, it may not prevent horizontal privilege escalation if users can still manipulate the URL to access other users' profiles. Proper input validation and sanitization is needed to address this vulnerability.

q_webattk_race_conditions_secp8

Which type of application vulnerability can refer to software flaws associated with the timing or order of events within a software program, which can cause undesirable or unpredictable outcomes through manipulation?

Answers:

***Race conditions**

Memory injection

Buffer overflow

Malicious update

Explanation:

Application race condition vulnerabilities refer to software flaws associated with the timing or order of events within a software program, which can cause undesirable or unpredictable outcomes through manipulation.

Memory injection vulnerabilities refer to a type of security flaw where an attacker can introduce (inject) malicious code into a running application's process memory.

To exploit a buffer overflow vulnerability, the attacker passes data that deliberately floods a space of temporary memory.

A malicious update refers to an update that appears legitimate but contains harmful code, often used by cybercriminals to distribute malware or execute a cyberattack.

q_webattk_replay_attack_secp8

You are a network security engineer at a large corporation. During a routine security audit, you discover that the company's internal network is vulnerable to replay attacks. The network uses a simple challenge-response authentication protocol.

Which of the following actions should you recommend to mitigate this vulnerability?

Answers:

Implement SSL/TLS encryption for all data in transit.

***Implement a time-based one-time password (TOTP) system.**

Switch to a different authentication protocol like OAuth.

Disable all client-side scripting.

Explanation:

Implementing a time-based one-time password (TOTP) system can help prevent replay attacks and is the correct answer. In a TOTP system, the authentication token changes every few seconds, making captured authentication messages useless after a very short period of time.

While SSL/TLS encryption is important for protecting data in transit, it does not prevent replay attacks. Replay attacks involve capturing and retransmitting authentication messages, which can occur regardless of whether the data is encrypted.

Simply switching to a different authentication protocol like OAuth does not inherently make the network more secure. If the new protocol does not include protections against replay attacks, the network could still be vulnerable.

Disabling all client-side scripting would not prevent replay attacks. Replay attacks target the authentication protocol, not client-side scripts.

q_webattk_sql_01_secp8

Which of the following is subject to SQL injection attacks?

Answers:

***Database servers**

Web servers serving static content

Browsers that allow client-side scripts

ActiveX controls

Explanation:

A SQL injection attack occurs when an attacker includes database commands within user data input fields on a form, which subsequently execute on the server. The injection attack succeeds if the server does not properly validate the input to restrict the entry of characters that could end and begin a database command.

The following do not directly rely on database servers and are not subject to SQL injection attacks:

Web servers serving static content

Browsers that allow client-side scripts

ActiveX controls

q_webattk_sql_02_secp8

You have a website that accepts input from users for creating customer accounts. Input on the form is passed to a database server where the user account information is stored.

An attacker is able to insert database commands in the input fields and have those commands execute on the server.

Which type of attack has occurred?

Answers:

***SQL injection**

Buffer overflow

DLL injection

Cross-site scripting

Explanation:

A SQL injection attack occurs when an attacker includes database commands within user data input fields on a form, which subsequently execute on the server. The injection attack succeeds if the server does not properly validate the input to restrict the entry of characters that could end and begin a database command. SQL injection attacks are prevented by proper programming methods that prevent commands from occurring within form data or that filter data to prevent such attacks.

A buffer overflow occurs when an operating system or application does not properly enforce boundaries for how much and which type of data can be inputted. Hackers submit data beyond the size reserved for the data in the memory buffer, and the extra data overwrites adjacent memory locations. The extra data sent by the attacker could include executable code that might then be able to execute in privileged mode.

Cross-site scripting (XSS) is an attack that injects scripts into web pages. When the user views the web page, the malicious scripts run, allowing the attacker to capture information or perform other actions.

A DLL injection attack occurs when a program is forced to load a dynamic-link library (DLL). This DLL then executes under the security context of the running application and executes malicious code included with the injected DLL.

q_webattk_sql_03_secp8

An attacker inserts SQL database commands into a data input field of an order form used by a web-based application. When submitted, these commands are executed on the remote database server, causing customer contact information from the database to be sent to the malicious user's web browser.

Which practice would have prevented this exploit?

Answers:

***Implementing client-side validation**

Using the latest browser version and patch level

Installing antivirus, anti-spyware, pop-up blockers, and firewall software

Implementing a script blocker

Explanation:

Client-side validation should have been used on the local system to identify input errors in the order form before the data was sent to the server. In this example, if the user entered SQL commands in an order form field, the error would have been immediately detected and blocked before the data was submitted to the server.

Using the latest browser version and patch level, installing anti-malware software, and using a script blocker are valuable security measures. But these would not have prevented the exploit in this scenario.

q_webattk_sql_04_secp8

In 2011, Sony was targeted by an SQL injection attack that compromised over one million emails, usernames, and passwords.

Which of the following could have prevented the attack?

Answers:

***Careful configuration and penetration testing on the front end**

Scanning the operating system and application regularly for bugs and errors

Using VPN technology to protect client data when connecting from a remote system

Blocking, or at least monitoring, activity on ports 161 and 162

Explanation:

SQL attacks such as with Sony, United States Department of Energy, and MySQL could have been prevented with careful configuration and penetration testing on the front end.

One of the steps for preventing privilege escalation is to scan the operating system and application regularly for bugs and errors.

To defend against WPA/WPA2 cracking, use VPN technology to protect client data when connecting from a remote system.

The easiest way to prevent SNMP exploitation is to block, or at least monitor, activity on ports 161, 162, and any other port you've configured for SNMP traffic.

q_webattk_sql_05_secp8

SQL injections are a result of which of the following flaws?

Answers:

Web applications

***The database**

The web server

The file system

Explanation:

SQL injections happen when a SQL statement is entered in a data field and gets executed in the database.

Web applications, web servers, and the file system are not databases and are not directly impacted by SQL injections.

q_webattk_sql_06_secp8

Which of the following functions does a single quote (') perform in an SQL injection?

Answers:

***Indicates that data has ended and a command is beginning.**

Indicates that code is ending and a comment is being entered.

Indicates that everything after the single quote is a comment.

Indicates that the comment has ended and data is being entered.

Explanation:

A single quote (') indicates that data has ended and a command is beginning.

The double dashes (--) indicate that code is ending and a comment is being entered.

Comments are code that a program does not execute and are usually used for explanations or reminders for the coder. Applications know to ignore the comments.

q_webattk_ssrf_secp8

You are a security engineer at a large financial institution. You notice some unusual network traffic patterns indicating that internal resources are being accessed from the public-facing web server.

You suspect a Server-Side Request Forgery (SSRF) attack.

Which of the following actions should you take next?

Answers:

Implement rate limiting on the public-facing web server.

Implement input validation and sanitization on all user inputs.

Block all incoming traffic to the public-facing web server.

***Restrict the public-facing web server from making unnecessary outbound requests.**

Explanation:

One of the most effective ways to mitigate SSRF attacks is to restrict the public-facing web server from making unnecessary outbound requests. This can be achieved by implementing network-level controls to block outbound traffic from the server to internal resources or by configuring the server or application to deny all outbound requests unless they are absolutely necessary.

While rate limiting can help mitigate some types of attacks (like DDoS), it would not be effective against an SSRF attack. SSRF attacks do not rely on a high volume of requests but rather on exploiting the trust relationship between the server and other internal systems.

While input validation and sanitization are good security practices, they alone may not prevent SSRF attacks. Attackers can often craft malicious payloads that bypass common input validation techniques.

Blocking all incoming traffic to the public-facing web server would effectively take your website offline, which is not a practical solution.

q_webattk_web_secp8

While using a web-based order form, an attacker enters an unusually large value in the Quantity field.

The value they entered is so large that it exceeds the maximum value supported by the variable type used to store the quantity in the web application. This causes the value of the quantity variable to wrap around to the minimum possible value, which is a negative number.

As a result, the web application processes the order as a return instead of a purchase, and the attacker's account is credited with a large sum of money.

Which practices would have prevented this exploit? (Select two.)

Answers:

***Implementing client-side validation**

Using the latest browser version and patch level

Installing antivirus, anti-spyware, pop-up blockers, and firewall software

Installing the latest operating system updates

***Implementing server-side validation**

Explanation:

Client-side validation and server-side validation should have been used to identify input errors in the order form. In this example, if the user entered an invalid quantity in an order form field, client-side validation would have detected and blocked the error before the data was submitted to the server. Server-side validation should have also been used after the data was sent to the server to detect errors. Experienced attackers can circumvent client-side validation techniques by sending data to the server from outside the application's standard user interface, bypassing any input validation measures that may have been implemented on the client.

Using the latest browser version and patch level, installing the latest operating system updates, and using a script blocker are valuable security measures, but they would not have prevented the exploit in this scenario.

q_webattk_xml_injection_secp8

You are a security analyst at a software company. During a security audit, you discover that the company's web application is vulnerable to Extensible Markup Language (XML) Injection attacks.

The application uses XML to transport data between the client and the server.

Which of the following actions should you recommend to mitigate this vulnerability?

Answers:

Implement SSL/TLS encryption for all data in transit.

Use a less complex data format like JSON instead of XML.

***Implement proper input validation and sanitization.**

Disable all client-side scripting.

Explanation:

Implementing proper input validation and sanitization is a key defense against XML Injection attacks and is the correct answer. This includes validating and sanitizing all user inputs and also using techniques like parameterized queries or prepared statements to ensure that user input is not interpreted as code.

While SSL/TLS encryption is important for protecting data in transit, it does not prevent XML Injection attacks. XML Injection attacks manipulate the structure of XML data, which can occur regardless of whether the data is encrypted.

Simply switching to a less complex data format like JSON does not inherently make the application more secure. JSON is also susceptible to injection attacks (JSON Injection) if proper security measures are not in place.

Disabling all client-side scripting would not prevent XML Injection attacks. XML Injection attacks target the server-side processing of XML data, not client-side scripts.

sql_attack_question1

What is Blake Jackson's account balance?

Answers:

$582.29

582.29

sql_attack_question2

What is the account number of Nisha Dickson?

Answers:

90003

8.9 Application Development and Security

As you study this section, answer the following questions:

- What are two common standardized software development models?
- How should security be implemented in the different stages of development?
- What are the responsibilities of developers after a product is released?
- What are some important application hardening techniques?

In this section, you will learn to:

- Harden applications on Linux.
- Implement application whitelisting with AppLocker.
- Implement Data Execution Preventions (DEP).

The key terms for this section include:

Term	Definition

Normalization	Data reorganized in a relational database to eliminate redundancy by having all data stored in one place and storing all related items together.
Stored procedures	One or more database statements stored as a group in a database's data dictionary, which when called, executes all the statements in the collection.
Code obfuscation	The deliberate act of creating source or machine code that is difficult for humans to understand. In other words, the code is camouflaged.
Code reuse	Using the same code multiple times.
Dead code	Code that is non-executable at run-time, or source code in a program that is executed but is not used in any other computation.
Memory management	A resource management process applied to computer memory. It allows your computer system to assign portions of memory, called blocks, to various running programs to optimize overall system performance.
Third-party libraries	A library where the code is not maintained in-house.
Software Development Kits (SDKs)	A set of software development tools that can be installed as one unit.
Data exposure	Unintended exposure of personal and confidential data.
Fuzz testing	A software testing technique that exposes security problems by providing invalid, unexpected, or random data to the inputs of an application.
Code signing	The process of digitally signing (encrypting) executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.3 Explain the importance of change management processes and the impact to security. Version control

2.2 Explain common threat vectors and attack surfaces.

- Unsupported systems and applications

2.5 Explain the purpose of mitigation techniques used to secure the enterprise.

- Application allow list
- Patching
- Monitoring
- Hardening techniques
  - Installation of endpoint protection
  - Host-based firewall
  - Removal of unnecessary software

3.3 Compare and contrast concepts and strategies to protect data.

- Methods to secure data
  - Obfuscation

4.1 Given a scenario, apply common security techniques to computing resources.

- Secure baselines
  - Establish
- Application security
  - Input validation
  - Secure cookies
  - Static code analysis
  - Code signing
- Sandboxing

4.3 Explain various activities associated with vulnerability management.

- Identification methods
  - Application security

Static analysis

Dynamic analysis

4.5 Given a scenario, modify enterprise capabilities to enhance security.

Operating system security

SELinux

4.6 Given a scenario, implement and maintain identity and access management.

Provisioning/de-provisioning user accounts

Access controls

Least privilege

4.7 Explain the importance of automation and orchestration related to secure operations.

Use cases of automation and scripting

User provisioning

Resource provisioning

Security groups

Ticket creation

Enabling/disabling services and access

Integrations and Application programming interfaces (APIs)

Benefits

Efficiency/time saving

Enforcing baselines

Staff retention

Other considerations

Complexity

Cost

	Single point of failure Technical debt Ongoing supportability 5.1 Summarize elements of effective security governance. Policies Software development lifecycle (SDLC) 5.2 Explain elements of the risk management process. Risk analysis Exposure factor
TestOut Security Pro	3.2 Implement application defenses 3.2.1 Implement an application allow list

8.9.1 Development Life Cycle (Lesson Video)

Transcript:

In this lesson, we'll look at how to apply security concepts to software development. Even though you may not be a software developer yourself, most security professionals work with software engineers in some capacity. Just like other company resources, the applications they develop need to be properly secured.

Today, we'll look at the two most common development lifecycles to understand how you can secure each step throughout the development process.
The most widely used development model is the Waterfall model. It's called this because each step is completed before the next step is begun. Each step flows to the next like a waterfall.
The first step in a Waterfall model is Requirements. All requirements for the application need to be gathered from the client, user, or stakeholder. The next step is Design. This is when the software is documented, diagrammed, and designed. After that, we have Implementation. This is the actual coding and building of the application.
We then have the Testing phase. During this phase, a quality assurance team makes sure that the team met the requirements, that the code works properly across devices, and that security flaws and vulnerabilities were phased out.
After Testing comes the Deployment. This is when the application is released to a client or to the public. The final step is Maintenance. The application is in use in this phase, but it's monitored for bugs or problems that are quickly patched. This is an ongoing stage that continues throughout the app's life.
Understand that the application will likely go through some of these steps multiple times before moving on. For example, the application might go through the Design step five times before it's ready to move on to the Implementation step. Then the application may move from the Implementation stage back to the Design stage if a new feature needs to be added.
This entire development cycle is a slow process and may take months or years to complete. The Waterfall method lacks flexibility since the requirements determined in the beginning carry through to the end product.
A more agile approach was introduced in 2001 which approaches software development as a continuous, changing process with never-ending versions, bug fixes, and enhancements. This approach is aptly named Agile. One reason the Agile methodology is pragmatic is because security vulnerabilities are constantly addressed with new updates and fixes.

Unlike Waterfall, Agile doesn't work on the entire application at once. Instead, it breaks development into smaller time frames called Sprints. Each Sprint has a specific duration, usually two to three weeks. Within this time frame, developers work on a specific application feature.
These features typically go through the same stages that all applications go through, such as Requirements, Design, Development, Testing, and Deployment. At the end of the Sprint, the developers move on to the next feature.
With Agile, you perform testing throughout the development cycle to help catch security vulnerabilities early. Waterfall, on the other hand, leaves testing until the end of the cycle. This can cause testing time to be cut short to meet deadlines.
Coding errors and design flaws are the main causes of software vulnerabilities. We can categorize these errors into two types: compile errors and runtime errors.
A compile error refers to an error that occurs during the building or compilation stage. The error compromises the software implementation, which prevents it from running at all.
A runtime refers to an error that occurs while the software is running. The software begins execution, but it fails when it cannot resolve a problem it encounters.
During the coding and design phases, you can increase application security by integrating security testing into each step of the process. Let's look at three testing methods: static, dynamic, and interactive application security testing.
Static application security testing, or SAST, is also known as white box testing. SAST focuses on analyzing source code, binaries, and byte code early in the development process. SAST tools are good at identifying things like SQL-injection vulnerabilities and buffer overflows. They can identify the exact cause of a coding problem, but only in code not yet deployed. They're language specific, but you can run them continually and apply them widely. Please note that they do have a high percent of false positives and are limited in the types of vulnerabilities they can detect.
Dynamic application security testing, or DAST, is also known as black box testing. DAST scans a deployed application once it enters runtime. The results are based on how the application responds to a series of tests from the outside. These tests aren't language specific and have a lower rate of false positives. The downsides to DASTs are that they're hard to automate, can't pinpoint the exact cause of a flaw, and can take up to a week to complete.
Finally, we have interactive application security testing, or IAST, which can be broken down into two types: passive and active. In passive IAST, we build interactivity into static application security testing. IAST tools are source code scanners that work during runtime.
In active IAST, the testing tools can access interpreters and compliers, allowing precise identification of a problematic line of code during runtime. This speeds up the testing and remediation process. The combination of passive and active IAST can help us in the development stage by catching vulnerabilities early, in the QA stage by adding automated security checkpoints, and in the production stage through continuous monitoring.
That's it for this lesson. In this lesson, we reviewed two common software development lifecycles: Waterfall and Agile. Then we looked at two different kinds of coding errors: compile errors and runtime errors. We finished up by looking at static, dynamic, and interactive application security testing and how these tools can help us secure applications throughout the development lifecycle.

8.9.2 Automation and Scripting (Lesson Video)

Transcript:

Automation is a powerful tool for managing security operations. Automation allows us to perform repetitive, rule-based tasks to improve efficiency and reduce user errors. Combining automation systems with orchestration and scripting can make a huge difference in the efficiency of security operations. In this lesson, we'll go over these systems and then look at the benefits and considerations of automation, orchestration, and scripting.

Automation uses software to perform repetitive, rule-based tasks, such as monitoring for threats, applying patches, maintaining baselines, or responding to incidents, to improve efficiency and reduce the likelihood of human error.
We can develop scripts to automate many of the common repetitive tasks. Scripts tell the system what steps to take to automate the task. Orchestration enhances automation by coordinating and streamlining the interactions between automated processes and systems. Orchestration supports seamless and integrated workflows, especially in large, complex environments with many different security tools and systems.
Scripting uses a specific language, such as Python, JavaScript, or PowerShell, to perform tasks on a computer or network system. A script is typically a text file with commands written that tell the system what to do step by step.
Typical programs must be compiled before running, which means the code's text must be converted into binary code. Scripts, on the other hand, are read and executed line by line. Scripting languages are usually something a human can

look at and interpret, whereas binary code is much more difficult to read. When combined, scripting and automation are critical tools in modern IT operations.

For all of these different platforms and tools to communicate with each other, we need to implement the appropriate Application Programming Interface, or API. An API simply serves as an interpreter between multiple systems so they can all speak the same language. Automation and orchestration systems will need an appropriate API so they can be integrated into the network systems.

Automation can help an organization to streamline processes, enhance security, and improve efficiency. For example, we can develop scripts to apply security policies on network devices and use automation software to help enforce the security policies. Another example is using scripts to apply patches and updates across the organization and automation tools to track the changes and notify us if anything goes wrong.

Using automation not only enhances the efficiency of security operations but also reduces the burden on the security team and reduces the likelihood of human error. Security analysts must monitor numerous systems for potential threats, manage high volumes of alerts, including many false positives, and respond to confirmed threats as quickly as possible. These working conditions often lead to long hours, anxiety, and elevated stress levels, resulting in operator fatigue. This fatigue is a significant concern in cybersecurity because it can lead to decreased alertness and cognitive function and impair the ability of security personnel to identify and respond to threats effectively. Fatigue results in missed critical alerts, slower response times, and a greater likelihood of errors, any of which can compromise security.

Having to perform common repetitive tasks, such as user and resource provisioning, assigning security groups, creating tickets, and other common tasks, can be minimized by creating scripts and monitoring with automation tools. This will greatly help reduce operator fatigue, leading to fewer errors and better security operations.

While implementing automation can make the job easier and more efficient, there are some challenges we need to be aware of. Appropriate automation and orchestration solutions can be extremely complex and require a deep knowledge and understanding of the organization's systems, processes, and interdependencies. A poorly planned or executed strategy will make systems more difficult to manage and maintain.

When implementing automation solutions, the initial cost can be quite high. Even though the organization will save money in the long term, the high initial cost can make it difficult to implement. If a critical automated system or process fails, this can impact multiple areas of the organization. Having this single point of failure is something that should be considered, and proper mitigation steps should be implemented.

If automation and orchestration systems are poorly designed and implemented, this can lead to system instability, complexity, and increased cost. This is known as technical debt. Lastly, automation systems require ongoing support and updates to stay effective and secure. Without proper support, these systems will be quickly outdated.

That'll wrap up this lesson on automation and scripting. In this lesson, we first went over what automation, orchestration, and scripting are. We then looked at the benefits of using these technologies, including reducing operator fatigue and increasing the efficiency of our security operations. We wrapped up by going over some concerns that should be considered when implementing automation orchestration solutions.

8.9.3 SDLC and Development Facts

Even though you may not be a software developer, most security professionals at some point work with software engineers who develop applications. And just like any other enterprise component, these applications need to be properly secured.

This lesson covers the following topics:

- Waterfall development life cycle model
- Agile development life cycle model
- Coding errors
- Error handling
- Static code analysis
- Software sandboxing

Waterfall Development Life Cycle Model

The most widely used development model is the Waterfall model. It is called this because each step is completed before the next step is begun so that each step flows to the next.

The Waterfall development life cycle model steps are:

Step	Description
Requirements	All requirements for the application being developed are gathered from the client, user, or stakeholder.
Design	The software is documented, diagramed, and designed.
Implementation	The code is written.
Testing	A quality assurance team makes sure requirements are met, the code works properly across devices, and security issues are noted.
Deployment	The application is released to a client or the public.
Maintenance	The application is monitored for bugs or problems that are patched or fixed while in use. This is an ongoing stage that continues throughout the life of the app.

Understand that an application will likely go through some of these steps multiple times before moving to the next step. For example, the application might go through the Design step five times before it's ready to move to the Implementation step. Or the application may move back from the Implementation stage to the Design stage if a new feature needs to be added.

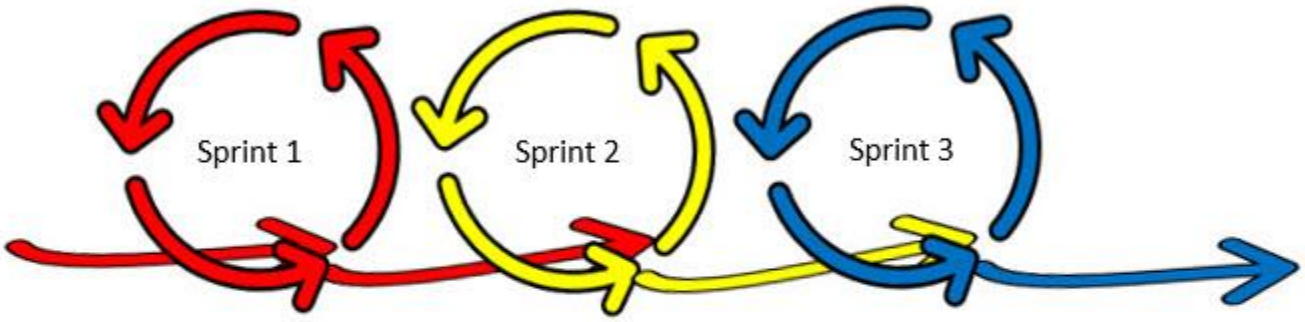
This entire development life cycle is a slow process and may take months or years to complete. The Waterfall method also lacks flexibility since the requirements determined in the beginning are carried through to the end product.

Agile Development Life Cycle Model

A more agile approach was introduced in 2001 that approaches software development as a continuous, changing process with never-ending versions, bug fixes, and enhancements. This approach is aptly named Agile.

The Agile model works in this manner:

- It breaks development into smaller time frames called Sprints.
  - Each Sprint has a specific duration (usually two to three weeks).
  - Developers work on one feature during a Sprint.
- At the end of each Sprint, developers move on to the next feature.
- Testing is performed throughout the development cycle.



1. Requirements	1. Requirements	1. Requirements
2. Design	2. Design	2. Design
3. Development	3. Development	3. Development
4. Testing	4. Testing	4. Testing
5. Deployment	5. Deployment	5. Deployment

Coding Errors

Coding errors and design flaws are the main causes of software vulnerabilities. We can categorize these errors into two types:

Coding Error Type	Description
Compile	An error that occurs during the building or compilation stage Error compromises the software implementation Prevents the app from running
Runtime	An error that occurs while software is running Sometimes called bugs

Error Handling

A well-written application must be able to handle errors and exceptions gracefully. This means that the application performs in a controlled way when something unpredictable happens. An error or exception could be caused by invalid user input, a loss of network connectivity, another server or process failing, etc. Ideally, the programmer will have written a structured exception handler (SEH) to dictate what the application should do. Each procedure can have multiple exception handlers.

Some handlers will deal with anticipated errors and exceptions; there should also be a catchall handler that will deal with the unexpected. The main goal must be for the application not to fail in a way that allows the attacker to execute code or perform some sort of injection attack. One infamous example of a poorly written exception handler is the Apple GoTo bug (nakedsecurity.sophos.com/2014/02/24/anatomy-of-a-goto-fail-apples-ssl-bug-explained-plus-an-unofficial-patch).

Another issue is that an application's interpreter may default to a standard handler and display default error messages when something goes wrong. These may reveal platform information and the inner workings of code to an attacker. It is better for an application to use custom error handlers so that the developer can choose the amount of information shown when an error is caused.

Technically, an error is a condition that the process cannot recover from, such as the system running out of memory. An exception is a type of error that can be handled by a block of code without the process crashing. Note that exceptions are still described as generating error codes/messages, however.

Static Code Analysis

Static code analysis is a crucial software development practice. It involves scrutinizing source code to identify potential vulnerabilities, errors, and non-compliant coding practices before the program is finalized. By examining code in a 'static' state, developers can catch and rectify issues early in the development lifecycle. This makes it a proactive approach to building secure, reliable, high-quality software.

Application security approaches focus on software development and deployment lifecycles, with a heavy emphasis on secure coding practices that encourage developers to write code that prevents common vulnerabilities like SQL injection and cross-site scripting. Application security practices also mandate static and dynamic application security testing (SAST). Coding practices designed to support regular patching and updates are crucial to support the prompt resolution of newly discovered vulnerabilities.

Static code analysis supports secure coding and is performed using specialized tools, often integrated into software development suites. These tools automate code checks against pre-determined rules and flag potential issues so developers can review and address them. Some commonly used static analysis tools include SonarQube (https://www.sonarsource.com/products/sonarqube/), Coverity (https://www.synopsys.com/software-integrity/security-testing/static-analysis-sast.html), and Fortify (https://www.microfocus.com/en-us/cyberres/application-security), but there are many others.

Static code analysis in software development is critical because it enables early detection of bugs and security vulnerabilities and helps prevent potentially catastrophic failures in the final product. It also improves code quality and maintainability by enforcing coding standards and best practices. Additionally, static code analysis helps educate developers about common coding errors and security risks, which helps promote security-conscious development practices.

During the coding and design phases of development, you can increase development and application security by implementing a few key practices. Integrate security testing into each step in the development process.

Secure Testing Method	Description
Static application security testing	Known as white box testing Focuses on analyzing source code, binaries, and byte code early in the development process Good at identifying things like SQL injections and buffer overflows Can identify the exact cause of a coding problem: Only in code that's written but not deployed

	Is language specific Can run continually and be widely applied Has a high percentage of false positives Limited in the types of vulnerabilities it can detect
Dynamic application security testing	Known as black box testing Scans applications after deployment Tests from the outside Uses a series of tests to determine vulnerabilities and flaws Not language specific Has fewer false positives Hard to automate Cannot pinpoint the cause of a flaw Can take up to a week to complete the testing process
Interactive application security testing	Has two types: Passive: Interactive functionality is built into static application security testing. Uses source code scanners during runtime. Active: Testing tools can access interpreters and compilers, allowing precise identification of a problematic line of code in runtime. Speeds up testing and remediation. Can help in the Development stage by catching vulnerabilities early. Can help in the QA stage by adding automated security checkpoints.

	Can help in the Production stage through continuous monitoring.

Software Sandboxing

Sandboxing is a security mechanism used in software development and operation to isolate running processes from each other or prevent them from accessing the system they are running on. A sandbox is a protection feature designed to control a program so it runs with highly restrictive access. This containment strategy reduces the potential impact of malicious or malfunctioning software, making it effective for improving system security and stability and mitigating risks associated with software.

A practical example of sandboxing is implemented in modern web browsers, like Google Chrome, which separates each tab and extension into distinct processes. If a website or browser extension in one browser tab attempts to run malicious code, it is confined within that tab's sandbox. This action prevents malicious code from impacting the entire browser or underlying operating system. Similarly, if a tab crashes, it doesn't cause the whole browser to fail, improving reliability.

Operating systems also utilize sandboxing to isolate applications. For example, iOS and Android use sandboxing to limit each application's actions. An app in a sandbox can access its own data and resources but cannot access other app data or any nonessential system resources without explicit permission. This approach limits the damage caused by poorly written or malicious apps.

Virtual machines (VMs) and containers like Docker offer another example of sandboxing at a larger scale. Each VM or container can run in isolation, separated from the host and each other. The others remain unaffected if one VM or container experiences a security breach or system failure.

8.9.4 Version Control Management (Lesson Video)

Transcript:

When you develop an application, the most valuable possession is the source code. Having it protected is critical. In this lesson, we'll discuss version control management as well as provisioning and deprovisioning, which aid in protecting the source code. In application development, there's usually a complex process of writing, revising, and updating the code since multiple developers work together on the same project. There are different ways to approach this reality as this creates a challenge when keeping track of changes in the code. In general, most organizations use a version control system, or VCS, to track these changes.

Let's look at how it works. A version control system uses a repository, which is a storage location that holds all the source files used during development. This centralized file system can be accessed by all authorized users. It allows developers to simultaneously work on the same file, revert to older files, and even restore files that were deleted. These repositories are often stored in the cloud or on a third-party website.
There are many benefits to using a VCS. For one, it has the flexibility to allow for branching and merging. This allows a developer to work on one specific feature in a branch that he or she created, and then merge it back into the source code when ready. It also keeps a history of code changes. This history includes the details of who, what, when, and why. Together with annotations that developers can add, a team can understand why the code was designed the way it was. This also helps prevent incompatibility issues without preventing the developers from continuing their work.
Now let's talk about provisioning. Provisioning is the process of giving access to users through privileges and permissions. It's important that developers and others working on a project have access to all the resources they need to do their work. This includes the permissions that you give in the VCS as well as in other areas of your system. It's important to only give permissions for specifically what a user needs and only until he or she no longer needs that access. If he or she moves on to another project, changes roles, leaves the organization, or if the project is complete, be sure to deprovision them. This means that you remove their privileges and permissions. This is the basic idea behind the principle of least privilege, which is important in application development just as it is throughout your organization.

That's it for this lesson. In this lesson, we discussed important secure coding techniques that include using a version control system to provide continuity, traceability, and protection throughout the development process. We then went over provisioning and deprovisioning as they apply to protecting the source code.

8.9.5 Application Development Security Facts

In our world today, information is exchanged constantly. This means that attackers are working relentlessly to access our data. It is essential that we begin security efforts at the coding level.

This lesson covers the following topics:

- Secure coding techniques
- Code signing
- Secure cookies

Secure Coding Techniques

The security considerations for new programming technologies should be understood and tested before deployment. One of the challenges of application development is that the pressure to release a solution often trumps any requirement to ensure that the application is secure. A legacy software design process might be heavily focused on highly visible elements, such as functionality, performance, and cost. Modern development practices use a security development lifecycle running in parallel or integrated with the focus on software functionality and usability. Examples include Microsoft's SDL (microsoft.com/en-us/securityengineering/sdl) and the OWASP Software Assurance Maturity Model (owasp.org/www-project-samm). OWASP also collates descriptions of specific vulnerabilities, exploits, and mitigation techniques, such as the OWASP Top 10 (owasp.org/www-project-top-ten).

Secure coding concepts include the following:

Concept	Description
Normalization	Normalization is data reorganized in a relational database with the intent to eliminate redundancy by having all related data stored in one place. Normalization: Increases performance by reducing disk space. Provides quick and efficient access to manipulate the data. Lowers the risk of exploitation.
Stored procedures	Stored procedures are one or more database statements stored as a group in a database's data dictionary. When called, these procedures execute all the statements in the collection. Stored procedures: Centralize the code and eliminate the need to reproduce it. Keep calling program rules consistent across programs.

	Protect the code from users by allowing the user to call a stored procedure without seeing the actual code. Limit injection attacks.
Code obfuscation/code camouflage	Obfuscation is the deliberate act of creating source or machine code that is difficult for humans to understand. In other words, the code is camouflaged. Programmers use roundabout expressions to compose statements that deliberately obfuscate code to conceal its purpose or logic. They use implicit values embedded in it to prevent tampering, deter reverse engineering, or as a puzzle or recreational challenge for someone reading the source code. This is usually done with an automated tool but can also be done manually. There are several methods, but most can be reverse-engineered.
Code reuse	Code reuse is simply using the same code multiple times. Reusing code is a good idea if the programmer writes the same code at least three times. Code reuse: Can create a shared library for others that use the same code. Can be a security problem if: The code is not secure before it is shared and used multiple times. It has changes made to fit a new use, but the changes are not secure. Be sure to comprehensively test code before allowing reuse.
Dead code	Sometimes dead code refers to code that is non-executable at runtime. Sometimes, it means source code in a program that is executed but is not used in any other computation, making it obsolete. Remove any dead code from your application for security. If it does not exist, it cannot be exploited.
Memory management	Memory management is a resource-management process applied to computer memory. It allows your computer system to assign portions of memory called blocks to various running programs that optimize overall system performance. Many arbitrary code attacks depend on the target application having faulty memory management procedures. This allows the attacker to execute their own code in the space marked out by the target application. There are known unsecured practices for memory management that should be avoided, and checks for processing untrusted input, such as strings, to ensure that it cannot overwrite areas of memory.

	Memory management resides in the hardware, the operating system, programs, and applications. In the hardware, memory management involves components that physically store data, such as RAM chips, memory caches, and SSDs. In the OS, memory management involves the allocation of specific memory blocks to individual programs as user demands change. At the Application level, memory management ensures the availability of adequate memory for the objects and data structures of each running program at all times. When the program requests a block of memory, the allocator in the memory manager assigns that block to the program. When a program no longer needs the data in the previously allocated memory blocks, those blocks become available for reassignment. This task can be done automatically by the memory manager or manually by the programmer. The most common memory vulnerabilities include: Size of input in buffer copy not checked Buffer size was calculated incorrectly Format string not controlled To prevent vulnerabilities: Limit the amount of characters read into the buffer. Define constants for the size argument. Do not allow user input in format strings.
Third-party libraries and software development kits (SDKs)	A third-party library is a library where the code is not maintained in-house. A software development kit (SDK) is a set of software development tools that can be installed as one unit. Both can provide code frameworks or code snippets to help development go faster. Though they can be very helpful, there are risks involved. For example: Anytime code comes from an outside source, there is a risk that it may contain flaws and vulnerabilities Sometimes code comes in bundles, giving developers more code than they need Extra code can create extra opportunities for exploitation SDKs are often open-source and, as such, there may be no urgency to fix bugs Be sure to test code from third-party libraries and SDKs for functionality and security issues.
Sensitive data exposure	Sensitive data exposure involves unintended exposure of personal and confidential data. This can come from:

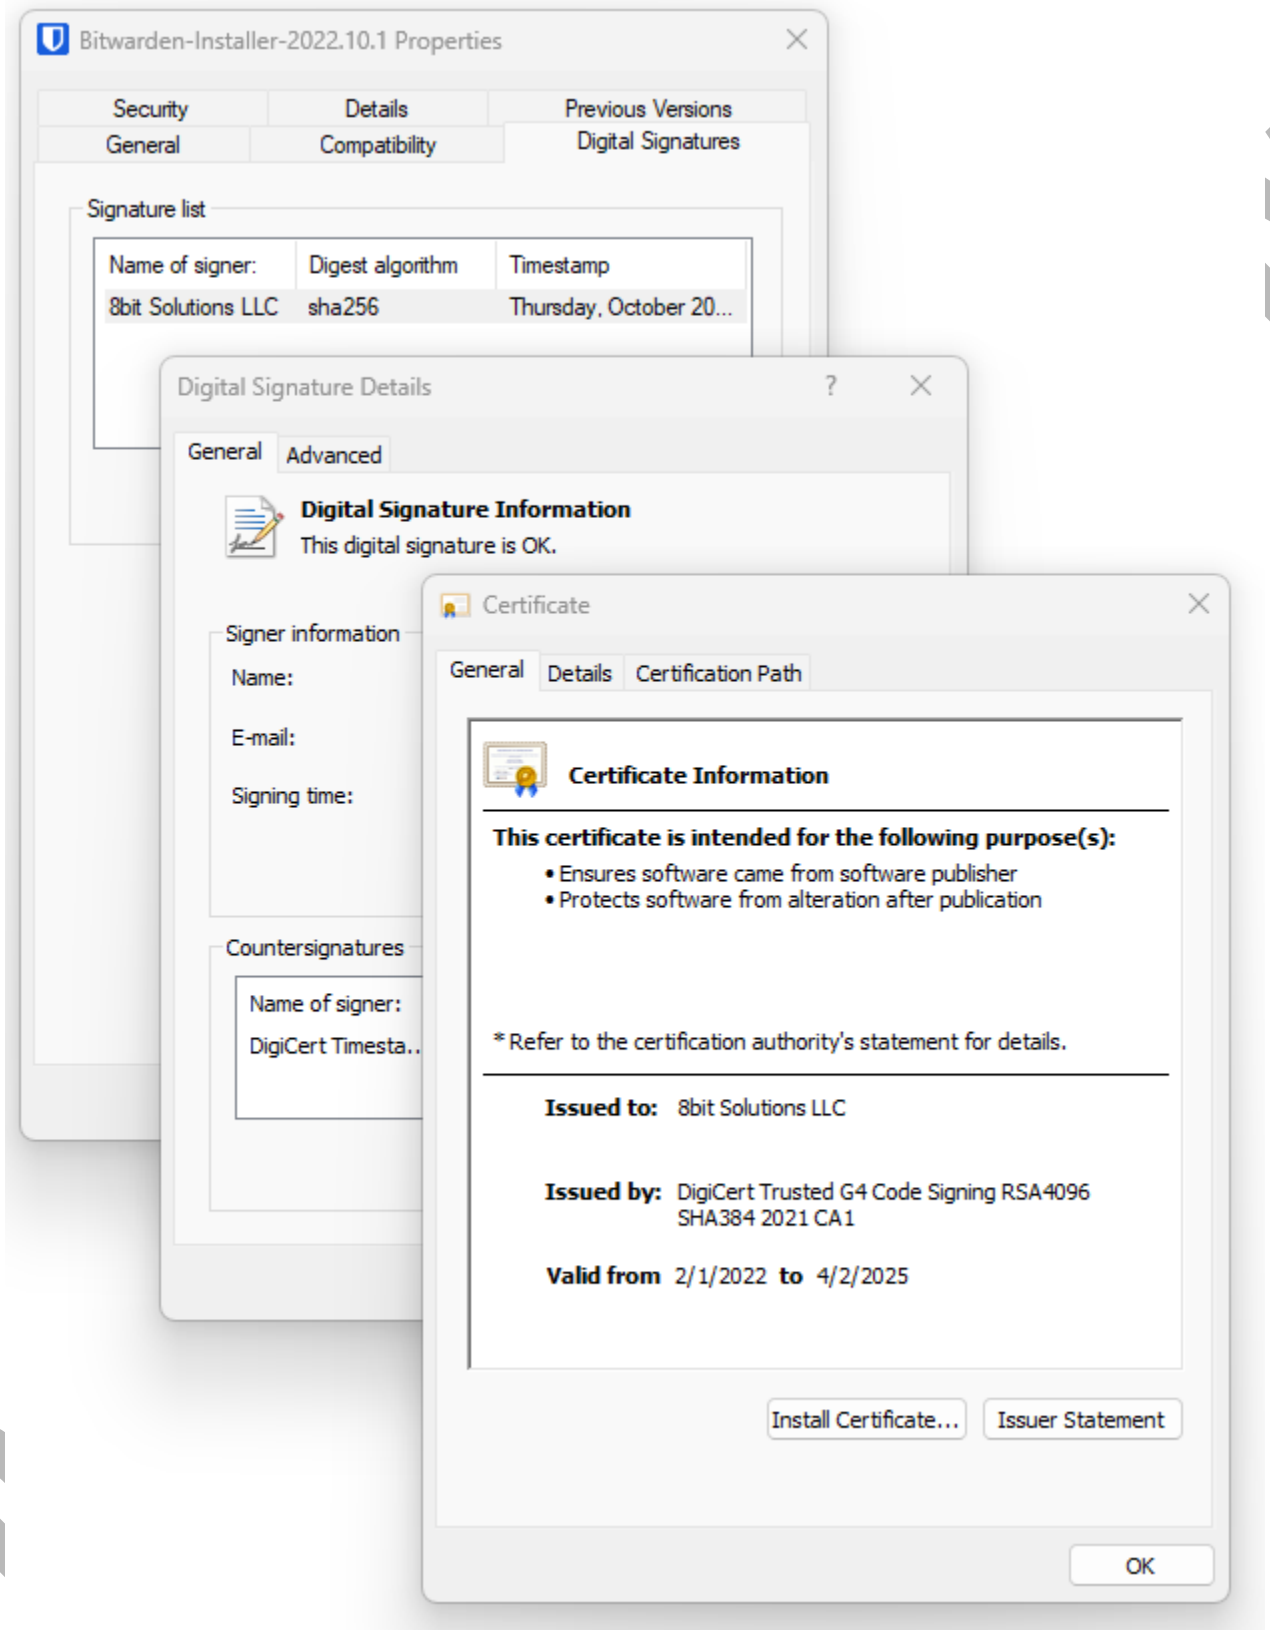
	Weak or missing encryption Coding flaws Misapplied data uploads in a database To mitigate sensitive data exposure: Encrypt data in transit and at rest using cryptographic algorithms and keys. Disable caching on forms that collect data. Implement hashed and salted passwords.
Fuzz testing	Fuzz testing (also known as fuzzing) is a software testing technique that exposes security problems by providing invalid, unexpected, or random data to the inputs of an application. Fuzzing program types are: Mutation-based Mutate existing data samples to create data Generation-based Define new test data based on models of the input

Code Signing

Code signing practices use digital signatures to verify the integrity and authenticity of software code. Code signing serves a dual purpose: ensuring that software has not been tampered with since signing and confirming the software publisher's identity.

When software is digitally signed, the signer uses a private key to encrypt a hash or digest of the code—this encrypted hash and the signer's identity form the digital signature. Code signing requires using a certificate issued by a trusted certificate authority (CA). The certificate contains information about the signer's identity and is critical for verifying the digital signature. If the certificate is valid and issued by a trusted CA, the software publisher's identity can be confidently verified. Code signing helps analysts and administrators block untrusted software and also helps protect software publishers by providing a mechanism to validate the authenticity of their code. Overall, code signing helps build trust in the software distribution process.

While code signing provides assurance about the origin of code and verifies code integrity, it does not inherently assure the safety or security of the code itself. Code signing certifies the source and integrity of the code, but it doesn't evaluate the quality or security of the code. The signed code could still contain bugs, vulnerabilities, or malicious code inserted by the original author. Signing ensures software is from the expected developer and in the state the developer intended. While code signing adds trust and authenticity to software distribution, it should not be relied upon to guarantee secure or bug-free code.



Reviewing the digital s ignature contained within the B itwarden Password Management app installer.

Data exposure is a fault that allows privileged information (such as a token, password, or personal data) to be read without being subject to the appropriate access controls. Applications must only transmit such data between authenticated hosts, using cryptography to protect the session. When incorporating encryption in code, it is important to use industry-standard encryption libraries that are proven to be strong, rather than i nternally developed ones.

Secure Cookies

Cookies are small pieces of data stored on a computer by a web browser while accessing a website. They maintain session states, remember user preferences, and track user behavior and other settings. Cookies can be exploited if not properly secured, leading to attacks such as session hijacking or cross-site scripting.

To implement secure cookies, developers must follow certain well-documented principles, such as using the 'Secure' attribute for all cookies to ensure they are only sent over HTTPS connections and protected from interception via eavesdropping, using the 'HttpOnly' attribute to prevent client-side scripts from accessing cookies and protect against cross-site scripting attacks, and using the 'SameSite' attribute to limit when cookies are sent to mitigate cross-site request forgery attacks. Additionally, cookies should have expiration time limits to restrict their usable life.

Secure cookie techniques are critical in mitigating several web-based application attacks, particularly those focused on unauthorized access or manipulation of session cookies. Developers can defend against attacks that target them by employing specific attributes within cookies.

8.9.6 Hardening Applications on Linux (Demo Video)

Transcript:

In this demonstration, we're going to look at how to harden applications or services on a Linux system. There are several different services you can use to harden applications or services. One of them is called SELinux. It's a cool access control security feature.

Essentially, the idea behind SELinux is that you use the operating system kernel to limit what a particular application is allowed to do, and it goes beyond the limitations that you set with permissions or privileges based on the user account. Think of it as a roadblock to help prevent hackers from doing more damage.
SELinux can be set to determine access between users, files, directories, memory, ports, and sockets. First, we're going to type â€˜sestatus'. this will tell us if SELinux is enforcing the system. Next, we'll take a look at the SELinux config file located in â€˜/etc/selinux/config'. This config file sets the permanent state of SELinux. It's recommended to set your system to permissive first, install all your needed applications, and then view the logs to make the necessary changes to SELinux. The permissive setting logs all the permission denied errors while allowing an application to run. Any changes to the SELinux config file located in /etc/selinux/config requires a reboot.
Two places we can look for SELinux permission denied errors are in the audit log and journalctl. Let's take a look at the audit log, â€˜less /var/log/audit/audit.log'. We're going to use a question mark and search for â€˜AVC', which is a type of SELinux error. As you can see, there's some denied messages from other applications that we should probably look at. Let's exit out of here and look at â€˜journalctl'. SELinux errors may be in red if there's a problem to address. We don't have much time to search through the logs right now, but this should give you a good idea of where to look.
If a service is unable to start, it might cause SELinux to deny permission to certain aspects that allow the application to run. When you need to determine the cause of a problem, logs are your friend. Let's type â€˜clear' to clear our screen. By default, SELinux has hundreds of Booleans that are essentially off and on switches for certain tasks. To view the whole list of Booleans, type â€˜getsebool -a'. Let's say I only want to see Booleans related to samba. Let's type â€˜getsebool -a | grep samba'. To enable a Boolean, we can use the setsebool command. There's one in particular that we want to enable called samba_share_nfs. This one grants samba rights to export NFS volumes. To set this, type â€˜setsebool samba_share_nfs 1 -P'. Now, if we go back and type â€˜getsebool -a | grep samba', you'll see that samba_share_nfs is set to On.
When SELinux is enforced, it uses a categorization system called context types. These are labels with addition information related to its purpose, user, role, and such. Today, we're just going to cover the basics. One useful command you can use to view the context type is the -Z flag. Let take a look at the context types for the samba configuration folder.

Type â€˜ls -lZ /etc/samba'. As you can see, there's additional information listed here that gives a label to samba so SELinux knows these are samba configuration files. If a configuration file was made in a /home directory and then copied to an /etc config directory, it may not have the right context type when copied. This could prevent applications from working correctly and show a denied message from SELinux in the logs.
And that's it for this demonstration. In this demo, we looked at hardening Linux applications using SELinux. We talked about how SELinux can protect your system using access control security. Then we saw some of the commands for managing SELinux and how to troubleshoot permission denied errors from SELinux.

8.9.7 Implementing Application Whitelisting with AppLocker (Demo Video)

Transcript:

In this demonstration, we'll practice implementing application deny and allow lists using AppLocker. AppLocker is a very useful feature of Windows. It allows you to control what applications are allowed or not allowed to run on machines in your domain.

As a real-world example of why you might do this, I had a junior administrator once that ran some registry cleaning software on a production SQL server, and it damaged SQL. The database would still run, but I was not able to upgrade it to a newer version of SQL. After I set up a new SQL server and got the database moved over and functioning, I took the time to set up some AppLocker rules. I downloaded every registry cleaning software I could find and made Deny rules in AppLocker, so no one would ever be able to run a registry cleaner on a production server again.
You can use it to accomplish such things as preventing malware from being installed, preventing unsupported applications from being installed.
The process of implementing application block and allow lists is fairly complex.
First, you must implement the rules for executable files. Then, you test those rules to verify that they are working as you expect without negatively affecting users.
After you analyze events created by AppLocker, you can then modify the rules and enforce them.
Let's begin with the first step of defining the executable rules. In this scenario, we'll enforce the AppLocker policy settings using Group Policy.
By doing this, anytime a user logs into the domain, the AppLocker settings are automatically enforced. Let's open the Group Policy Manager.
The default domain policy would be a bad choice of Group Policy objects (GPOs) to use. Improperly configured Applocker rules can render your system completely inoperable. If you put your rules in the Default Domain Policy and they don't work as expected, you're going to cause widespread problems across your whole domain. So, let's create a new GPO called Applocker. Let's right-click it and select Edit. We're going to resize this screen so we can see what's going on a little better.
Under Computer Configuration, we'll expand Policies > Windows Settings > Security Settings > Application Control Policies.
When we expand AppLocker, we can see these sets of application rules we can use. Let's select AppLocker and click Configure rule enforcement.
For our purposes today, we'll focus on Executable rules. We'll select the Configured checkbox here. After that we need to define whether we want to enforce those rules or just audit them.
We'll choose to audit only for now. You could immediately enforce the rules if you wanted, however, in a production environment you want to make sure that the rules you define work properly for the end users in the organization.
When we select Audit, the events are generated by AppLocker and we can access those in Event Viewer. We can analyze Event Viewer events to decide whether the rules are working correctly or whether we need to modify them.
Let's go to Executable Rules. Notice that there are no rules here. We're enforcing them, but there are no rules to enforce. So, let's right-click here and select Create New Rule.
In the Before You Begin screen, it tells you how the rule works and some preparatory steps you need to follow.
For example, you need to make sure that the applications you want to create the rule for are installed on this system. We've already done that. There are other steps, but we don't need to worry about them. Let's click Next.
Now we have to specify the action to be used in the AppLocker rule. As noted up here, an allow action permits the affected files to run.
A deny action, on the other hand, prevents the files from running. We want to use an Allow rule. Another thing we do on this page is specify who this rule applies to.

The application we are allowing is called SalesBuilder. It's used by the Sales department. As such, we want this rule to apply only to the Sales group.
So, let's specify that this rule applies to the Sales group by clicking Select. We'll type in Sales and click Check Names. Windows has found the group, so we'll click OK. Click Next.
At this point, we need to specify the primary condition that will be used in the rule. We have three options. We'll use the Path option.
We would use the Publisher option if the application we want to create the rule for is signed by a known software publisher, but since ours is an in-house application that isn't signed, we can't' use that option. Let's click Next.
Now we need to specify the path to the application. We'll click Browse Folders and let's browse to the folder where the executable resides. It's SalesBuilder; select it. Notice that we have two options for specifying a path.
We can specify a file or specify a folder. Because we want the rule to apply to all files in the SalesBuilder folder, we specified a folder instead of a file. Click Next. We don't want to create any exceptions. The default rule name isn't very friendly, so I'm going to give this rule a more descriptive name.
Notice that we're presented with this dialogue here. It tells us that we've created a custom rule, but there are default rules that should be created so that important system files will still be able to be run.
If you don't create these default rules, you may not be able to run most of the applications that you need. Let's create the default rules along with the rule we just defined by clicking Yes.
And there you go. Notice that the default rules allow basically full access to anyone in the administrator's group.
The Everyone group is allowed access to all files located in the Windows folder and it is also allowed access to files that are installed in the Program Files folder.
We had to create this custom rule because SalesBuilder is not installed in the Program Files folder. It's installed in the root directory of the C: drive. We created a special rule that allows the Sales group to run the application.
It's important to know that the rules we just configured won't be applied to any users who are currently logged in while we defined these rules.
The rules won't take effect until those users log out and log back in, or until you run GPUpdate on the workstation.
Now, it's important to note that AppLocker uses the Application Identity service on individual workstations to verify the attributes of the executable files we specified in our executable rules. Therefore, we need to make sure that the Application Identity service is always started by default. We can do this using Group Policy.
By doing this when the user logs into the domain, we enforce the AppLocker rules and we make sure that the Application Identity service automatically runs as well.
So, let's edit our AppLocker policy again. We'll go to Computer Configuration > Policies > Windows settings > Security Settings.
Under Security Settings let's select System Services. Over here in the right pane, we'll right-click Application Identity. And then we'll define this to start automatically. Click OK.
With the rules configured and the Application Identity service starting automatically, we can test our AppLocker policy. We can have end users log in to the domain, run the application as they normally would, and then we analyze the AppLocker events.
Based on what we see in Event Viewer, we would decide whether the rules we set up are functioning correctly. If they are, we can enforce the policy. If not, we would go in and modify the policy to work the way it should.
That's it for this demonstration. In this demo, we implemented application block and allow lists with AppLocker.

8.9.8 Implement Application Whitelisting with AppLocker (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You are increasing network security by implementing application whitelisting.

Your first step is to prevent applications not located in the operating system directory or the program files directory from running on your computers. In addition, the call center application used by the support team runs from C:\CallCenter\CallStart.exe and must be allowed to run. You also want any future versions of the call center application to run without changing any settings.

In this lab, your task is to configure AppLocker in the default domain policy as follows:

- Create the default rules.

Allow all files located in the Program Files folder.

Allow all files located in the Windows folder.

Configure a publisher rule that will allow future updates from the same vendor.

Allow the **Support** group to run the call center software found in **C:\CallCenter\CallStart.exe** .

Explanation

Complete this lab as follows:

Access the CorpNet.local domain under Group Policy Management.

From the Server Manager's menu bar, select **Tools** > **Group Policy Management** .

Maximize the window for better viewing.

Expand **Forest: CorpNet.local** > **Domains** > **CorpNet.local** .

Access the AppLocker policy.

Right-click **Default Domain Policy** and select **Edit** .

Maximize the window for better viewing.

Under *Computer Configuration* , expand and select:
Policies > **Windows Settings** > **Security Settings** > **Application Control Policies** > **AppLocker** .

Configure rule enforcement.

From the right pane, select **Configure rule enforcement** .

Under Executable rules, select **Configured** .

Make sure **Enforce rules** is selected in the drop-down list.

Select **OK** .

Configure a Publisher rule and allow the **Support** group to run the call center software.

From the left pane, expand **AppLocker** .

Right-click **Executable Rules** and then select **Create New Rule** .

Select **Next** .

Make sure **Allow** is selected.

For *User or group* , click **Select** .

In the *Enter the object names to select* box, type **Support** , and then select **OK.**

Select **Next** .

Make sure **Publisher** is selected, and then select **Next** .

For the Reference file, select **Browse** .

Browse to and select the **C:\CallCenter\CallStart.exe** file.

Select **Open** .

Slide the pointer from *File version* to **Publisher** and then select **Next** .

Select **Next** .

Accept the ***default name*** and select **Create** .

Select **Yes** to create the default rules.
Notice that the Publisher rule was created.

8.9.9 Implementing Data Execution Preventions (Demo Video)

Transcript:

In this demonstration, we're going to practice working with Data Execution Prevention, or DEP.

DEP is a set of hardware and software technologies designed to prevent malicious code from running on a Windows system.
DEP looks for and blocks a malicious program or any other type of attack that has injected a process with malicious code and is trying to run that code. Let's look at how this works.
Let's start with a Windows system. If I right-click Start, select System, come over to Advanced system settings, go to Performance Settings on the Advanced tab, and then go to the Data Execution Prevention tab. In Windows Server 2022, DEP is enabled by default for all programs, except those the user selects.
It's possible that DEP will trigger a false positive. This means that DEP thinks a legitimate process that's running on the system is malicious and shuts it down.
This is particularly relevant in situations where you have in-house programmers who create custom applications for your organization.
In-house developed applications sometimes aren't as rigorously tested, so they might kick off an exception where DEP detects them and thinks that they're malicious code.
But notice you do have the option to turn off DEP for specific applications. We have a case where we can do that on this system.
I'm going to come down here to File Explorer. If I go to my C: drive, then into Program Files, and then to the SalesBuilder folder, there's an application called SalesBuilder.
This is an in-house written application. It wasn't extensively tested and will kick off an exception when we try to run it if DEP is monitoring all system processes.
Let's hit Add and go to Program Files > SalesBuilder > SalesBuilder.exe. Now DEP is turned on for everything except SalesBuilder. We hit Apply.
Verify that DEP is Enforced
DEP is now enforced. DEP is now on for all services except SalesBuilder.
This means that whenever a process is run on this system, whether it's a service or application, DEP will watch it and look for any instance where it's trying to run code from places that it shouldn't. Except, of course, for the one application that I specified earlier, SalesBuilder, which DEP was told not to worry about because I know that I trust it.

That's it for this demonstration. In this demo, we configured Data Execution Prevention, or DEP.

8.9.10 Implement Data Execution Preventions (Simulation)

Scenario

You work as the IT security administrator for a small corporate network. You are configuring the computer in Office 1 to use Data Execution Prevention (DEP) for all programs and services. You have noticed that the accounting program used on some computers does not function well when DEP is enabled.

In this lab, your task is to configure DEP as follows:

Enable DEP for all files.

Disable DEP for **C:\Program Files (x86)\AccountWizard\AccountWizard.exe** .

Restart the computer to activate DEP.

Explanation

Complete this lab as follows:

Access the Advanced system settings (System Properties).

Right-click **Start** and then select **System** .

Maximize the window for better viewing.

From the right pane, under *Related settings* , select **System protection** .

Select the **Advanced** tab.

Configure Data Execution Prevention.

Under Performance, select **Settings** .

Select the **Data Execution Prevention** tab.

Select **Turn on DEP for all programs and services except those I select** .

Select **Add** .

Open the **C:\Program Files (x86)\AccountWizard** folder.

Select **AccountWizard.exe** .

Select **Open** .

Make sure **AccountWizard.exe** is selected, and then click **OK** .

Select **OK** to confirm that a system restart is needed.

Select **OK** to close System Properties.

Select **Restart Now** to restart the computer and activate DEP.

Wait for the computer to restart.

8.9.11 Hardening Applications Facts

Application hardening is the process of preventing the exploitation of vulnerabilities in software applications. Applications pose the most difficult security challenges for a security administrator because they are complex, usually developed by a third party, and designed to accept input from users.

This lesson covers the following topics:

Application hardening guidelines

Application hardening techniques

Input validation

Monitoring capabilities

Application Hardening Guidelines

Basic hardening guidelines for applications are as follows:

Assume all installed applications are flawed.

Remove all unused applications from the system.

Limit administrative privileges.

Install security software, such as antivirus, anti-spyware, and anti-rootkit software.

Use firewalls, content filters, and operating system user-authentication features.

Restrict access to the application and provide access only to those who need it.

Update all applications with the latest patches when security bulletins are released.

Identify baselines.

Application Hardening Techniques

Additional application hardening includes the following techniques:

Technique	Description

Block process spawning	Process spawning is the creation of a new process (also called a child process) by an existing process (also called a parent process). If you take the process-spawning ability from the application, threat agents cannot perform process-spawning attacks.
Control access to executable files	Executable files should be protected from modification by removing the Write permissions given to applications.
Protect OS components	Sensitive file system areas (such as Windows Registry keys) should be protected by removing Write permissions given to specific applications. In most cases, applications do not need to modify sensitive areas of the system for them to function properly.
Use exception rules	Exception rules allow an administrator to bypass a specific hardening rule when an application has a legitimate need. Administrators should exercise caution and set parameters regarding the exceptions that ensure the security of the system.
Use Data Execution Prevention	Data Execution Prevention (DEP) is a security feature that can help prevent damage to your computer from viruses and other security threats. DEP ensures that applications use computer memory safely. DEP closes an application and notifies the administrator if a program initiates run instructions from the portion of memory used for data.
Implement third-party application hardening tools	Third-party application hardening systems are developed for specific applications. The rules used by the application hardening system can be applied to the application being hardened, including libraries and SDKs. An example of these tools is AppArmor for Linux systems.

Input Validation

Input validation is an essential protection technique used in software and web development that addresses the issue of untrusted input. Untrusted input describes how an attacker can provide specially crafted data to an application to manipulate its behavior. Injection attacks exploit the input mechanisms applications rely on to execute malicious commands and scripts to access sensitive data, control the operation of the application, gain access to otherwise protected back-end systems, and disrupt operations.

OWASP provides an excellent overview of input validation at https://cheatsheetseries.owasp.org/cheatsheets/Input_Validation_Cheat_Sheet.html .

Without effective input validation, applications are vulnerable to many different classes of injection attacks, such as SQL injection, code injection, cross-site scripting (XSS), and many others.

Monitoring Capabilities

Secure coding practices focus primarily on preventing software vulnerabilities and stress enhancements to logging and monitoring capabilities. These features support security analysts tasked with detecting potential threats and malicious activity in software. Writing code with enhanced monitoring capabilities improves the granularity and effectiveness of logging and alerting systems, which are crucial system monitoring tools.

Implementing comprehensive and meaningful logging requires developers to ensure their applications generate logs that capture important events and activities to support security audits, incident response, and system troubleshooting. Secure coding practices encourage robust error handling to hide or mask sensitive debugging information, and this practice minimizes the risk of attackers

exploiting information displayed in error messages. Integrating real-time alerting capabilities within the application code can significantly improve threat detection. For example, code that triggers alerts when specific events occur, such as repeated failed login attempts or unusual data transfers, helps security analysts monitor applications more effectively. These alerts often indicate a potential security breach and provide crucial information for incident response teams.

8.9.12 Practice Questions (Section Quiz)

q_sdlc_agile_secp8

Which application development model approaches software development as a continuous, changing process with never-ending versions, bug fixes, and enhancements?

Answers:

***Agile**

Waterfall

Fuzz testing

Code signing

Explanation:

The Agile development model approaches software development as a continuous, changing process with never-ending versions, bug fixes, and enhancements.

The Waterfall development model is the most widely used model. It is called this because each step is completed before the next step is begun. This way, each step flows to the next.

Fuzz testing is a software testing technique that exposes security problems by providing invalid, unexpected, or random data to the inputs of an application.

Code signing is the process of digitally signing (encrypting) executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed.

q_sdlc_catchall_handler_secp8

You are a software developer working on a complex application. During the testing phase, you notice that the application crashes unexpectedly when certain unpredictable events occur.

You have implemented a try-catch block to handle anticipated errors, but the application still crashes on unanticipated errors.

What should you do to ensure the application handles these errors gracefully and does not reveal any sensitive information about the system or the code?

Answers:

***Implement a catchall handler.**

Ignore the unanticipated errors, as they are rare.

Use default error handlers provided by the application's interpreter.

Remove the try-catch block, as it is not effective.

Explanation:

Implementing a catchall handler is the correct solution. A catchall handler is designed to handle all types of errors, including those that are unanticipated. This ensures that the application does not crash and does not reveal sensitive information when an unexpected error occurs.

Ignoring the unanticipated errors is not a good solution. Even though these errors might be rare, they can still cause the application to crash or behave unpredictably. Ignoring them does not solve the problem and can lead to serious security issues.

Using default error handlers provided by the application's interpreter is not the best solution. These handlers often display default error messages that can reveal platform information and the inner workings of the code to an attacker.

Removing the try-catch block is not a good solution. The try-catch block is designed to handle anticipated errors. Removing it would leave these errors unhandled, which could lead to crashes or unpredictable behavior.

q_sdlc_dast_secp8

A software development team is working on an application that will handle sensitive user data. The team has already implemented static application security testing (SAST) in the early stages of development.

As the application nears deployment, what additional secure testing method should the team consider implementing and why?

Answers:

***Dynamic application security testing (DAST) because it can test the application after deployment and from the outside.**

Additional static application security testing (SAST) because it can identify the exact cause of a coding problem.

Interactive application security testing (IAST) because it can access interpreters and compilers, allowing precise identification of a problematic line of code in runtime.

No additional testing is needed because SAST is sufficient for ensuring the security of the application.

Explanation:

Dynamic application security testing (DAST) because it can test the application after deployment and from the outside is the correct answer. Dynamic application security testing (DAST) is a good complement to SAST because it tests the application in its running state from the outside, mimicking an attacker's perspective. This can help identify vulnerabilities that SAST might miss, such as runtime errors and server configuration issues.

While additional SAST can be beneficial, it is not the best choice in this scenario. SAST is most effective in the early stages of development and primarily focuses on analyzing source code, binaries, and byte code. It may not identify vulnerabilities that only become apparent when the application is running.

Interactive application security testing (IAST) can be a good choice, but it is not the best in this scenario. While IAST can identify problematic lines of code in runtime, it requires a higher level of integration with the application and may not be as effective as DAST in identifying vulnerabilities from an external perspective.

While SAST is an important part of secure testing, it should not be the only method used. SAST focuses on the internal structure of the application and may not identify vulnerabilities that only become apparent when the application is running or when it is attacked from the outside.

q_sdlc_dynamic_secp8

You are performing a security test from the outside on a new application that has been deployed.

Which secure testing method are you MOST likely using?

Answers:

Static

Interactive

***Dynamic**

Runtime

Explanation:

Dynamic application security testing scans applications after they have been deployed. These tests are performed from the outside.

Static application security testing focuses on analyzing source code, binaries, and byte code early in the development process.

Interactive application security testing is built into static testing and uses source code scanners.

Runtime is a type of coding error that occurs while software is running.

q_sdlc_require_secp8

Which of the following is the first step in the Waterfall application development model?

Answers:

Design

Implementation

***Requirements**

Maintenance

Explanation:

The Waterfall development life cycle model steps are:

Requirements

Design

Implementation

Testing

Development

Maintenance

q_sdlc_seh_secp8

You are a software developer working on a new application. During the testing phase, you notice that the application crashes unexpectedly when certain unpredictable events occur, such as loss of network connectivity or invalid user input.

You need to ensure that the application handles these errors gracefully and does not reveal any sensitive information about the system or the code.

Which of the following would be the MOST effective solution to this problem?

Answers:

***Implement a structured exception handler (SEH).**

Use default error handlers provided by the application's interpreter.

Ignore the errors as they are unpredictable and cannot be prevented.

Use a try-catch block without a catchall handler.

Explanation:

Implementing a structured exception handler (SEH) is the correct solution. SEH is a mechanism that allows a program to intercept and respond to exceptional conditions such as errors. It allows the application to handle errors gracefully and prevents the application from crashing or revealing sensitive information.

Using default error handlers provided by the application's interpreter is not the best solution. These handlers often display default error messages that can reveal platform information and the inner workings of the code to an attacker.

Ignoring the errors is not a good solution. Even though these errors are unpredictable, they can still cause the application to crash or behave unpredictably. Ignoring them does not solve the problem and can lead to serious security issues.

Using a try-catch block without a catchall handler is not the best solution. While this approach can handle some anticipated errors, it does not provide a solution for unexpected errors. Without a catchall handler, unexpected errors can cause the application to crash or behave unpredictably.

q_sdlc_software_sandboxing_secp8

You are a security analyst at a software development company. Your company is developing a new application that will handle sensitive user data.

To ensure the security of the application, you are considering various security measures. One of your colleagues suggests using software sandboxing.

How would implementing software sandboxing contribute to the security of the application?

Answers:

It would encrypt the user data to prevent unauthorized access.

***It would isolate the application from the rest of the system, limiting the potential damage from security vulnerabilities.**

It would detect and remove malware from the application.

It would detect and remove malware from the application.

Explanation:

Isolating the application from the rest of the system is the correct answer. Software sandboxing is a security mechanism that isolates an application in a separate environment to prevent it from interacting with the rest of the system. This limits the potential damage that can be caused if the application has security vulnerabilities.

Software sandboxing does not directly involve encryption. While encryption is a valuable security measure for protecting data, it is not the primary function of a sandbox.

While sandboxing can help to contain malware if it is present within the sandboxed application, it does not actively detect or remove malware. Other security measures, such as antivirus software, are needed for this purpose.

Software sandboxing does not prevent users from inputting invalid data. Input validation is a separate security measure that needs to be implemented in the application's code.

q_sdlc_software_secp8

Which of the following are the two main causes of software vulnerabilities? (Select two.)

Answers:

***Coding errors**

Fuzzing

Normalization

***Design flaws**

Obfuscation

Explanation:

Coding errors and design flaws are the main causes of software vulnerabilities.

Fuzz testing (also known as fuzzing) is a software-testing technique that exposes security problems by providing invalid, unexpected, or random data to the inputs of an application.

Normalization is data reorganized in a relational database with the intent to eliminate redundancy. This is done by having all related data stored in one place. This is not one of the main causes of software vulnerabilities.

Obfuscation is the deliberate act of creating source or machine code that is difficult for humans to understand. This is not one of the main causes of software vulnerabilities.

q_sdlc_sprint_secp8

A software development team is using the Agile development life cycle model for a new project.

During a sprint, they realize that a feature they are working on is more complex than initially thought and cannot be completed within the current sprint.

What should the team do?

Answers:

Continue working on the feature past the end of the sprint until it is completed.

Drop the feature from the project.

***Break the feature down into smaller tasks and distribute them over the next few sprints.**

Move on to the next feature and return to the complex feature in a future sprint.

Explanation:

Breaking the feature down into smaller tasks and distributing them over the next few sprints is the correct answer. In Agile, if a task or feature is too large to be completed within a sprint, it should be broken down into smaller, manageable tasks. These tasks can then be distributed over the next few sprints. This approach maintains the time-boxing principle of Agile and allows for complex features to be developed in a manageable way.

One of the principles of Agile is time-boxing, where work is confined to a regular, repeatable work cycle. Extending the sprint to accommodate a complex feature goes against this principle and can disrupt the project timeline.

Dropping the feature from the project is not a good solution unless the feature is deemed unnecessary or unfeasible. Agile promotes adaptive planning and evolutionary development, but it doesn't mean dropping a feature just because it's complex.

Moving on to the next feature and returning to the complex feature in a future sprint is not the best choice. While it's important to keep the project moving, simply postponing the complex feature may lead to a backlog of unfinished tasks. It's better to break down the feature into smaller tasks and tackle them over the next few sprints.

q_sdlc_waterfall_secp8

Which of the following is considered a drawback of the Waterfall application development life cycle?

Answers:

Development is broken into Sprints.

Testing is performed throughout development.

***Requirements are determined at the beginning and are carried through to the end product.**

Each step in the life cycle only needs to be completed once before moving on to the next one.

Explanation:

The Waterfall development life cycle is a slow process and may take months or years to complete. It also lacks flexibility since the requirements determined in the beginning are carried through to the end product.

Development is broken into Sprints when using the Agile development model.

The Agile development model performs testing throughout development.

When using the Waterfall development model, an application likely goes through some of these steps multiple times before moving on to the next step.

q_app_devsec_code_obfuscation_secp8

John, a software developer, is working on a project that involves creating a proprietary algorithm for his company.

He wants to ensure that even if someone gets access to the source code, they would have a hard time understanding the logic and purpose of the code.

Which secure coding concept should John use?

Answers:

Code reuse

***Code obfuscation**

Stored procedures

Normalization

Explanation:

Code obfuscation is the correct answer. Code obfuscation involves making the source or machine code difficult for humans to understand. It can be used to conceal the purpose or logic of the code, making it a good choice for John's situation.

Code reuse involves using the same code multiple times. While it can increase efficiency, it does not inherently protect the code from being understood if accessed.

Stored procedures are a group of one or more database statements stored in a database's data dictionary. While they can centralize code and limit injection attacks, they do not make the code difficult to understand.

Normalization is a process in database design to minimize redundancy and dependency by organizing fields and tables of a database. It does not make the code difficult to understand.

q_app_devsec_code_secp8

You have just finished developing a new application. Before putting it on the website for users to download, you want to provide a checksum to verify that the object has not been modified.

Which of the following would you implement?

Answers:

Memory management

Code obfuscation

***Code signing**

Normalization

Explanation:

Code signing is the process of digitally signing (encrypting) executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed. The process employs the use of a cryptographic hash to validate authenticity and integrity.

Code signing:

Provides security when deployed.

Helps prevent namespace conflicts in some programming languages.

Provides a digital signature mechanism to verify the identity of the author or build system.

Provides a checksum to verify that the object has not been modified.

Provides versioning information about an object as well as storing other metadata about the object.

Memory management is a resource-management process applied to computer memory.

Code obfuscation is the deliberate act of creating source or machine code that is difficult for humans to understand.

Normalization is data reorganized in a relational database with the intent to eliminate redundancy by having all related data stored in one place.

q_app_devsec_fuzz_secp8

Which fuzz testing program type defines new test data based on models of the input?

Answers:

***Generation-based**

Code signing

Memory management

Mutation-based

Explanation:

Fuzz testing (also known as fuzzing) is a software-testing technique that exposes security problems by providing invalid, unexpected, or random data to the inputs of an application. Fuzzing program types are:

Mutation-based programs

Mutate existing data samples to create data

Generation-based programs

Define new test data based on models of the input

Code signing is the process of digitally signing (encrypting) executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed.

Memory management is a resource-management process applied to computer memory.

q_app_devsec_memory_management_secp8

You are a software engineer working on a large-scale application.

During a code review, you notice that a fellow developer has written a function that allocates a large block of memory but does not deallocate it before the function ends.

What potential issue could this lead to?

Answers:

Code obfuscation

***Memory leak**

Code reuse

Fuzz testing

Explanation:

Memory leak is the correct answer. A memory leak occurs when a program allocates memory but fails to deallocate it, leading to a gradual loss of available memory. This can eventually cause the program or even the entire system to crash due to lack of memory.

Code obfuscation involves making the source or machine code difficult for humans to understand. It does not directly relate to memory management or the allocation and deallocation of memory.

Code reuse involves using the same code multiple times. While it can increase efficiency, it does not directly relate to memory management or the allocation and deallocation of memory.

Fuzz testing is a software testing technique that involves providing invalid, unexpected, or random data to the inputs of an application. While it can help identify security vulnerabilities, it does not directly address the issue of memory management.

q_app_devsec_sdk_secp8

What is a set of software development tools called that can be installed as one unit and provides code frameworks or code snippets to help development go faster?

Answers:

Repository

***SDK**

Code signing

Memory management

Explanation:

A software development kit (SDK) is a set of software development tools that can be installed as one unit. These tools can provide code frameworks or code snippets to help development go faster.

A version control system uses a repository, which is a storage location that holds all the source files used during development.

Code signing is the process of digitally signing (encrypting) executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted since it was signed.

Memory management is a resource-management process applied to computer memory.

q_app_devsec_secure_cookies_secp8

You are a security analyst at a tech company developing a new web application. The development team has implemented cookies to maintain user sessions. You are tasked with ensuring the security of these cookies.

Which of the following approaches would you recommend to the team?

Answers:

Implement secure cookies but allow them to be transmitted over HTTP connections.

***Implement secure cookies and ensure they are only transmitted over HTTPS connections.**

Avoid using cookies altogether and use URL parameters to maintain user sessions.

Implement secure cookies and store user credentials in them for easy access.

Explanation:

Implementing secure cookies and ensuring they are only transmitted over HTTPS connections is the most secure approach. HTTPS encrypts the data between the client and the server, which helps protect the cookies from being intercepted and read by unauthorized parties. Therefore, this is the correct answer.

Implementing secure cookies but allowing them to be transmitted over HTTP connections is not a secure approach. Even though the cookies are secure, transmitting them over HTTP can expose them to man-in-the-middle attacks. Therefore, this is not the best answer.

Avoiding the use of cookies altogether and using URL parameters to maintain user sessions is not a secure approach. URL parameters are visible in the browser's address bar and can be stored in browser history, bookmarks, and web server logs. This could potentially expose sensitive session information. Therefore, this is not a good answer.

Implementing secure cookies and storing user credentials in them for easy access is a very insecure approach. If an attacker manages to steal the cookie, they would have direct access to the user's credentials. Therefore, this is not a good answer.

q_app_devsec_sensitive_data_secp8

As a lead software developer, you are reviewing the code of a new application developed by your team. The application collects personal information from users, including their names, addresses, and credit card details.

You notice that the data is stored in plain text in the database and transmitted over the network without any encryption.

What security issue is MOST directly associated with this situation?

Answers:

Code obfuscation

Code reuse

***Sensitive data exposure**

Fuzz testing

Explanation:

Sensitive data exposure is the correct answer. Sensitive data exposure involves unintended exposure of personal and confidential data. Storing and transmitting sensitive data in plain text without any encryption is a direct example of sensitive data exposure.

Code obfuscation involves making the source or machine code difficult for humans to understand. While it can be used to protect the logic and purpose of the code, it does not directly address the issue of protecting sensitive data.

Code reuse involves using the same code multiple times. While it can increase efficiency, it does not inherently protect sensitive data.

Fuzz testing is a software testing technique that involves providing invalid, unexpected, or random data to the inputs of an application. While it can help identify security vulnerabilities, it does not directly address the issue of protecting sensitive data.

q_app_hard_exception_rules_secp8

As a security administrator, you have been tasked with hardening a critical application in your organization's IT infrastructure.

The application is complex and developed by a third party. It is also designed to accept input from users. The application has unique functionalities necessary for business operations but may pose security risks.

Which of the following application hardening techniques would be the BEST solution for you to use?

Answers:

Block process spawning.

Control access to executable files.

***Use exception rules.**

Implement third-party application hardening tools.

Explanation:

Exception rules allow an administrator to bypass a specific hardening rule when an application has a legitimate need. This technique is important for maintaining the functionality of the application while also ensuring its security. Given the unique functionalities of the application that are necessary for business operations, using exception rules would be the BEST solution for you to use.

Block process spawning involves preventing the creation of a new process (also called a child process) by an existing process (also called a parent process). Blocking process spawning can help prevent process spawning attacks. However, this might not be the highest priority if the application does not have functionality that involves process spawning or if the unique functionalities of the application require process spawning.

Control access to executable files involves protecting executable files from modification by removing the Write permissions given to applications. This is a critical step in application hardening as it prevents unauthorized changes to the application's executable files. However, this might not be the highest priority if the application's executable files are already well-protected and the unique functionalities of the application require certain permissions.

Third-party application hardening tools are developed for specific applications and can be applied to the application being hardened, including libraries and SDKs. While this could be a comprehensive approach to hardening the application, it might not be the highest priority if the unique functionalities of the application require specific exception rules that may not be covered by third-party tools.

q_app_hard_execution_prevention_secp8

You are a security administrator for a large corporation.

You've noticed that one of your applications is being exploited by a threat agent who initiates run instructions from the portion of memory used for data, causing system instability.

Which application hardening technique would be the MOST effective in this situation?

Answers:

Use exception rules

Monitor logs

***Use Data Execution Prevention**

Block process spawning

Explanation:

Use Data Execution Prevention is the correct answer. Data Execution Prevention (DEP) is a security feature that can help prevent damage from viruses and other security threats. DEP ensures that applications use computer memory safely. DEP closes an application and notifies the administrator if a program initiates run instructions from the portion of memory used for data, directly addressing the issue at hand.

Exception rules allow an administrator to bypass a specific hardening rule when an application has a legitimate need. However, in this case, the issue is not about exceptions to hardening rules but about preventing a threat agent from exploiting the application's memory usage.

Monitoring logs is an important part of maintaining system security, as it allows administrators to identify potentially vulnerable applications and detect if an application is being exploited. However, while this technique can help identify the problem, it does not directly prevent the threat agent from exploiting the application's memory usage.

Blocking process spawning is a technique used to prevent the creation of new processes by existing ones. This is not the most effective solution in this case, as the issue is not related to process spawning but to the application's memory usage.

q_app_hard_guideline_secp8

Which of the following is a basic hardening guideline for applications?

Answers:

Grant administrative privileges to all users.

Assume all installed applications are flawless.

***Update all applications with the latest patches when security bulletins are released.**

Allow unrestricted access to the application.

Explanation:

Updating all applications with the latest patches when security bulletins are released is a correct guideline. Regularly updating applications with the latest patches is crucial for maintaining security, as patches often fix known vulnerabilities.

Granting administrative privileges to all users is a security risk. It's better to limit administrative privileges to only those who absolutely need them.

It's a good security practice to assume that all installed applications might have vulnerabilities, as this encourages proactive security measures.

Restricting access to applications helps to minimize the potential attack surface and limit the potential damage if a breach does occur.

q_app_hard_input_validation_secp8

You are a software developer at a tech company and are currently working on a new web application. You are tasked with implementing input validation to prevent potential security threats.

Which of the following approaches would be the MOST effective way to ensure input validation?

Answers:

Implement client-side validation only.

Implement server-side validation only.

***Implement both client-side and server-side validation.**

There is no need for input validation as the application uses secure coding practices.

Explanation:

Implement both client-side and server-side validation is the correct answer. This is the most secure and user-friendly approach. Client-side validation provides immediate feedback to the user, while server-side validation ensures that even if the client-side validation is bypassed, invalid data will not be processed.

While client-side validation can provide immediate feedback to the user and help reduce server load, it can be easily bypassed by a malicious user. Therefore, relying solely on client-side validation is not a secure approach.

Server-side validation is crucial as it cannot be bypassed by the user. However, relying solely on server-side validation may not provide the best user experience as it requires a round trip to the server before the user gets feedback.

Even with secure coding practices, input validation is still necessary. Secure coding practices can help prevent vulnerabilities, but they cannot guarantee that all input will be safe. Input validation is a crucial part of secure coding practices.

q_app_hard_monitoring_secp8

You are a security analyst at a tech company reviewing the monitoring capabilities of a recently developed web application. You notice that the application logs are not capturing some important events and activities.

Which of the following actions would be the MOST effective way to enhance the monitoring capabilities of the application?

Answers:

Increase the frequency of log reviews.

Implement real-time alerting for specific events.

Remove unnecessary log entries to reduce noise.

***Implement a third-party monitoring tool.**

Explanation:

Implementing a third-party monitoring tool is the correct answer. A third-party monitoring tool can provide additional monitoring capabilities that the application may not currently have. This can help ensure that all important events and activities are captured in the logs. However, it's also important to work with the development team to enhance the application's built-in logging capabilities.

While increasing the frequency of log reviews can help identify issues more quickly, it does not address the problem of the application not capturing important events and activities.

Real-time alerting can help detect potential security threats more quickly. However, if the application is not logging important events and activities, real-time alerting may not be fully effective.

While reducing noise in the logs can make it easier to identify important events, it does not address the problem of the application not capturing these events in the first place.

q_app_hard_os_components_secp8

As a security administrator for your company, you have noticed that certain applications have been modifying sensitive areas of the system, leading to potential security vulnerabilities.

Which application hardening technique would be the MOST effective in this situation?

Answers:

Use Data Execution Prevention

***Protect OS components**

Use exception rule

Monitor logs

Explanation:

Protect OS components is the correct answer. Protecting OS components involves removing Write permissions given to specific applications for sensitive file system areas (such as Windows Registry keys). This directly addresses the issue of applications modifying sensitive areas of the system.

While Data Execution Prevention (DEP) is a valuable security feature that can help prevent damage from viruses and other security threats, it is not the most effective solution in this case. DEP ensures that applications use computer memory safely, but it does not directly prevent applications from modifying sensitive system areas.

Exception rules allow an administrator to bypass a specific hardening rule when an application has a legitimate need. However, in this case, the issue is not about exceptions to hardening rules but about preventing applications from modifying sensitive system areas.

Monitoring logs is an important part of maintaining system security, as it allows administrators to identify potentially vulnerable applications and detect if an application is being exploited. However, while this technique can help identify the problem, it does not directly prevent applications from modifying sensitive system areas.

q_app_hard_process_spawning_secp8

You are a security administrator for a large corporation. One of your applications has been experiencing frequent attacks where threat agents are creating new processes from existing ones, leading to system instability and potential data breaches.

Which application hardening technique would be the MOST effective in this situation?

Answers:

Use exception rules.

Monitor logs.

***Block process spawning.**

Implement third-party application hardening tools.

Explanation:

Block process spawning is the correct answer. Blocking process spawning is the creation of a new process (also called a child process) by an existing process (also called a parent process). By taking the process spawning ability from the application, threat agents are not able to perform process spawning attacks, directly addressing the issue at hand.

While exception rules can be useful in certain situations, they are not the most effective solution in this case. Exception rules allow an administrator to bypass a specific hardening rule when an application has a legitimate need, but they do not directly address the issue of process spawning.

Monitoring logs is a crucial part of maintaining system security, as it allows administrators to identify potentially vulnerable applications and detect if an application is being exploited. However, while this technique can help identify the problem, it does not directly prevent process spawning.

While third-party application hardening tools can be useful, they may not specifically address the issue of process spawning. These tools are typically designed to apply a set of predefined rules to an application, and while they may include rules related to process spawning, this is not guaranteed.

9.0 Incident Response

9.1 Incident Response and Mitigation

As you study this section, answer the following questions:

Why is the chain of custody so important in a forensic investigation?

How do you ensure the integrity of collected digital evidence?

When conducting a forensic investigation, what methods can you use to save the contents of memory?

What would a computer forensic investigator analyze when conducting a live analysis compared to a dead analysis?

What actions should you take when an incident occurs?

Key terms for this section include the following:

Term	Definition
Security incident	An event, or series of events, resulting from a security policy violation. A security incident has adverse effects on a company's ability to proceed with normal business.
Incident response	The action taken to deal with an incident, both during and after the incident.
First responder	The first person on the scene after a security incident has occurred.
Damage assessment	A preliminary onsite evaluation of damage or loss caused by a security incident.
Live analysis	An incident investigation that examines an active (running) computer system to analyze the live network connection, memory contents, and running programs.
Dead analysis	An incident investigation that examines data at rest, such as analyzing hard drive contents.
Big data analysis	An incident investigation that examines all types of data used in the organization, including text, audio, video, and log files. The investigation identifies anomalies that led up to the security incident.
Corroborative evidence	Evidence or information that supports another fact or detail.
Hearsay evidence	Evidence that is obtained from a source who doesn't have personal, firsthand knowledge.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Segmentation Isolation 4.8 Explain appropriate incident response activities. Process Preparation Detection Analysis Containment Eradication Recovery Lessons learned 5.1 Summarize elements of effective security governance. Procedures Playbooks
TestOut Security Pro	5.2 Assessment techniques 5.2.4 Analyze network attacks 5.2.5 Analyze password attacks

9.1.1 Incident Response Process (Lesson Video)

Transcript:

Incident response is a systematic approach to handling and managing the aftermath of a security breach or cyberattack, also known as an IT incident, computer incident, or security incident. The goal is to handle the situation in a way that limits damage and reduces recovery time and costs.

The incident response lifecycle provides a structured approach to addressing and managing the aftermath of a security breach or cyberattack to limit damage and reduce recovery time and costs. The incident response lifecycle includes seven steps: preparation, detection, analysis, containment, eradication, recovery, and lessons learned.
Part of the preparation step is to ensure that systems are resilient to attack. This includes hardening systems, writing policies and procedures, and setting up confidential lines of communication.

The preparation step also includes creating incident response resources and procedures. An Incident Response Plan is like a fire drill for cyber threats. Just as a fire drill outlines steps to evacuate a building safely, an Incident Response Plan contains instructions on how to react when a cyber-attack occurs.
The detection step discovers indicators of threat actor activity. Indicators that an incident may have occurred could be generated from an automated intrusion system or other monitoring and alerting systems. Incidents can also be detected using threat hunting methods or by reports made by employees or customers.
The containment phase is where immediate action is taken to prevent further damage or compromise of the system. This could involve disconnecting affected systems or devices from the network to prevent the spread of the breach. It's the equivalent of stopping the bleeding in a medical emergency, a quick and temporary fix to halt the immediate threat. Containment strategies can vary based on the severity and nature of the incident. After containment, an in-depth investigation leads to the next phase—eradication.
Next is the recovery phase. During this phase, systems and networks are returned to their normal function. All systems affected by the cyberattack are cleaned, restored, and put back into operation. Recovery may involve reinstalling system components, changing passwords, and patching software. System administrators should carefully monitor systems during recovery for any signs of abnormal activity, as this could indicate that not all threat elements have been successfully eradicated. Regular operations can resume once the systems are deemed secure and functioning normally. The recovery phase isn't considered complete until all systems are back operational and all data has been recovered.
The last phase in the incident response lifecycle is the "lessons learned" stage. During this phase, the incident response team conducts a post-incident review. This review aims to identify what went well during the response, what could've been done better, and what improvements can be made to the incident response process. It provides an opportunity to learn from the incident and improve future response efforts. The lessons learned may include changes to policies, procedures, or infrastructure. They may lead to further security and awareness training for employees.
That's it for this lesson. In this lesson, we've discussed incident response. We looked at the seven steps of the incident response lifecycle: preparation, detection, analysis, containment, eradication, recovery, and lessons learned.

9.1.2 Incident Response Process Facts

This lesson covers the following topics:

Security incident

Incident response process

Security Incident

A security incident is an event or series of events resulting from a security policy violation. The incident may or may not adversely affect an organization's ability to conduct business. It is crucial to organizations that security incidents are recognized and dealt with appropriately. The following table describes types of security incidents.

Type	Description
Employee errors	Unintentional actions by an employee that cause damage or leave network systems vulnerable to attack.
Unauthorized act by an employee	Intentional actions by an employee to cause harm to a company's network or data. This is also known as an insider threat.
External intrusion attempts	Intentional actions by a threat actor not employed by or associated with an organization to exploit attack vectors. The threat actor's intent is to harm an organization or profit from access to an organization's resources.

Type	Description
Virus and harmful code attacks	Tools used by threat actors to disrupt company business, compromise data, or hurt the company's reputation
Unethical gathering of competitive information	This is also known as corporate espionage. The goal is to obtain proprietary information to obtain a competitive advantage or steal clients.

Incident Response Process

A cybersecurity incident refers to either a successful or attempted violation of the security properties of an asset, compromising its confidentiality, integrity, or availability. Incident response (IR) policy sets the resources, processes, and guidelines for dealing with cybersecurity incidents. Management of each incident should follow a process lifecycle. CompTIA's incident response lifecycle is a seven-step process:

Preparation — makes the system resilient to attack in the first place. This includes hardening systems, writing policies and procedures, and setting up confidential lines of communication. It also implies creating incident response resources and procedures.

Detection — discovers indicators of threat actor activity. Indicators that an incident may have occurred might be generated from an automated intrusion system. Alternatively, incidents might be manually detected through threat hunting operations or be reported by employees, customers, or law enforcement.

Analysis — determines whether an incident has occurred and performs triage to assess how severe it might be from the data reported as indicators.

Containment — limit the scope and magnitude of the incident. Incident response aims to secure data while limiting the immediate impact on customers and business partners. It is also necessary to notify stakeholders and identify other reporting requirements.

Eradication — removes the cause and restores the affected system to a secure state by applying secure configuration settings and installing patches once the incident is contained.

Recovery — reintegrates the system into the business process it supports with the cause of the incident eradicated. This recovery phase may involve restoring data from backup and security testing. Systems must be monitored closely to detect and prevent any reoccurrence of the attack. The response process may have to iterate through multiple phases of identification, containment, eradication, and recovery to affect a complete resolution.

Lessons learned — analyzes the incident and responses to identify whether procedures or systems could be improved. It is imperative to document the incident. Outputs from this phase feed back into a new preparation phase in the cycle.

Incident response likely requires coordinated action and authorization from several departments or managers, which adds further complexity. The IR process is focused on cybersecurity incidents. There are also significant incidents that pose an existential threat to company-wide operations. These major incidents are handled by disaster recovery processes. However, a cybersecurity incident might lead to a major incident being declared.

9.1.3 Isolate and Contain (Lesson Video)

Transcript:

Today, we'll be discussing isolation, containment, and segmentation within network security. Let's get started.

Isolation is limiting the ability of a compromised asset or application from doing more harm to the network or its assets. This can be accomplished in a few different ways. One way is to practice process isolation. This ensures that if a process is compromised, only the resources used by that process are at risk. This practice applies to operating systems as well as RAM. In other words, it prevents any process that is limited by access bounds from accessing the resources of another process. This is a trait of a stable operating system. Isolation is considered a preventative security measure since it's implemented before an event is detected.
Containment is the first step after an event has been detected and identified. This action can take a few forms. An IT admin may disconnect a machine from the network by simply unplugging the Ethernet cable or disabling the NIC. If this network is connected to other networks, this connection may be terminated. The decision to disconnect must be weighed against the amount of data being compromised and the potential loss of forensic evidence. No matter what, the goal of containment is to limit the damage potential of malicious activity.
Containment requires action. Once an IT security analyst detects and identifies a malicious event, they must act. In this scenario, the analyst is monitoring a physical server that must be manually disconnected from network. This means the on-site IT Admin must jump into action as quickly as possible. Time is of the essence since this event threatens the physical server and also the servers in the branch office. This is because the two networks are connected via a VPN. Containment requires that the damage be limitedâ€”even if it means taking a server down.
Segmentation is a strategic network design. The concept is simple: keep sections of a network separated so that malicious actors can't pivot within a network. Segmentation can be accomplished through VLANs, software-defined networks, switches, subnetting, or even physical segmentation.
But simply being on a different subnet is not enough. Rules must be implemented to control what kind of communications can occur between assets on the network. Many times, a network admin will create a DMZ. This a virtual area where assets are kept separate from internal network assets. A network with a DMZ may have a single firewall or two firewalls depending on how secure this segment needs to be. No matter the topography, access between the DMZ and the internal network is secure and controlled.
That's it for this lesson. We discussed isolation and how it's used to protect a network. Next, we talked about containment, which is the first action taken once an event has been detected. We ended by discussing network segmentation and how it can prevent unauthorized access.

9.1.4 Isolate and Contain Facts

This lesson covers the following topics:

- Isolation, containment, and segmentation
- Security Orchestration, Automation, and Response (SOAR)
- Incident plans

Isolation, Containment, and Segmentation

Data, whether good or malicious, must be handled correctly. You can use isolation and containment for malicious or suspect data. You can use segmentation as a strategic network architecture tool to prevent outside data from accessing internal network appliances.

Strategy	Description
Isolation	Isolation limits the ability of a compromised process or application to do more harm to the network or its assets. One way to protect the network is process isolation. This ensures that if a process is compromised, only the resources used by that process are at risk.

Strategy	Description
Containment	Containment is the first step after an event has been detected and identified. This action can take a few forms. You can disconnect a machine from the network by unplugging the Ethernet cable or disabling the NIC. If a network is connected to other networks, you can terminate those connections.
Segmentation	Segmentation is a strategic network design. The concept is simple: separate the network sections so malicious actors cannot pivot within a network. You can segment using VLANs, software-defined networks, switches, subnetting, or physical segmentation. Being on a different subnet is not enough. You must implement rules to control the kind of communications that occur between assets on the network. You can also create a demilitarized zone (DMZ). It is a virtual area where you separate assets from internal network assets. Depending on how secure the segment needs to be, a network with a DMZ may have a single firewall or two firewalls. No matter the topography, access between the DMZ and the internal network is access-controlled.

Security Orchestration, Automation, and Response (SOAR)

SOAR is a platform to compile security data generated by different security endpoints. This collected information is then sent to a security analyst for further action. SOAR frees an analyst from constantly receiving security alerts as they are generated. Analysts can use parameters to automate solutions for security incidents that meet specific criteria. SOAR:

- Gathers alert data and places it in a specified location.
- Facilitates application data integration.
- Facilitates focused analysis.
- Creates a single security case.
- Allows for multiple playbooks and playbook step automation.

Incident Plans

As part of the incident response process, you can use playbooks and runbooks together to achieve a more effective response that can be automated and include tasks automatically assigned to analysts to complete. These two plans can also help to meet and comply with regulatory frameworks like GDPR or NIST if necessary.

Plan Type	Description
Runbooks	Runbooks are a condition-based series of protocols you can use to establish automated processes for security incident response. Assessment, investigation, and mitigation are accelerated using a runbook. Even though processes are automated, human analysis is still used in some cases.
Playbooks	A playbook is a checklist-style document specifying how to respond to a threat or incident. The steps are listed in the order to be performed. A playbook ensures a consistent approach to security issues.

9.1.5 Summarize Incident Response Procedures

9.1.6 Practice Questions (Section Quiz)

q_incident_resp_analyze_01_secp8

A large organization's cybersecurity incident response team receives an alert indicating potential threat actor activity on one of its network servers.

What should be the team's immediate action based on the incident response life cycle?

Answers:

Wait for more alerts to confirm the incident before taking any action.

Immediately disconnect the affected server from the network to isolate it.

***Analyze the alert and its context to determine whether a genuine incident has occurred.**

Notify the executive decision-maker to authorize actions before proceeding.

Explanation:

When receiving an alert, the first responder's immediate action is to determine whether a genuine incident has occurred. This action involves investigating the data reported and assessing the severity of the situation before taking further action.

Waiting for more alerts to confirm the incident is not advisable. Immediate analysis is necessary to assess the severity of the situation and determine whether it is a genuine incident.

Immediately disconnecting the affected server from the network might disrupt business operations and hinder the investigation. The organization should analyze the incident before taking such drastic action.

Notifying the executive decision-maker to authorize actions before proceeding would delay acting on the threat and potentially cause serious damage to the network server.

q_incident_resp_analyze_02_secp8

The computer incident response team (CIRT) has informed the executives of a large financial institution of unusual network activity, indicating a potential breach.

Which phase of the incident response lifecycle involves investigating the reported unusual network activity to determine whether a genuine security incident has occurred and assessing the severity of the situation?

Answers:

***Analysis**

Preparation

Containment

Eradication

Explanation:

During the incident response life cycle, the analysis phase is where the CIRT must investigate the reported unusual network activity to determine whether a genuine security incident has occurred and to assess the severity of the situation.

The preparation phase focuses on setting up security measures, policies, and communication lines to prevent incidents.

The containment phase occurs after the analysis phase and involves limiting the scope and magnitude of the incident to prevent further damage. It focuses on securing data and minimizing the immediate impact on customers and business partners.

The eradication phase follows containment and involves removing the intrusion tools and unauthorized changes from the systems after the CIRT has contained the incident.

q_incident_resp_containment_01_secp8

A cybersecurity analyst in a multinational corporation is responsible for sensitive customer data and proprietary information and is now dealing with a security breach.

The team is managing the incident response process using the CompTIA incident response life cycle. The team has just completed the third step in the process.

What must the team do next?

Answers:

Preparation

Detection

Analysis

***Containment**

Explanation:

Containment is the fourth step in the CompTIA incident response lifecycle, as it involves limiting the scope and magnitude of the incident, securing data, and notifying stakeholders.

The first step in the CompTIA incident response life cycle is preparation, which focuses on making the system resilient to attacks and setting up incident response resources and procedures.

The second step in the CompTIA incident response life cycle is detection, which discovers indicators of threat actor activity. Indicators that an incident may have occurred might be generated from an automated intrusion system. Alternatively, incidents might be manually detected through threat hunting operations or be reported by employees, customers, or law enforcement.

The third step in the CompTIA incident response life cycle is analysis, which determines whether an incident has occurred and performs triage to assess how severe it might be from the data reported as indicators.

q_incident_resp_containment_02_secp8

A multinational manufacturing company's Chief Information Officer (CIO) heavily depends on its digital infrastructure for managing supply chains and production.

Recently, the IT team detected some unusual activity on the company's network that might indicate a potential malware infection.

The incident response team is now following the CompTIA incident response life cycle to tackle the issue. As the CIO guides them through the different phases, they need to highlight the primary objective of the containment phase.

Which of the following options will they be highlighting?

Answers:

Restoring the affected system to a secure state.

Identifying indicators of threat actor activity.

***Securing data and limiting the immediate impact.**

Analyzing the incident and improving procedures or systems.

Explanation:

The primary aim of the containment phase is to secure data while limiting the immediate impact on customers and business partners. This phase involves preventing the incident from spreading further and notifying stakeholders.

Restoring the affected system to a secure state is the goal of the eradication phase, which comes after containment and involves removing the incident's root cause.

Identifying indicators of threat actor activity is the goal of the detection phase, where the incident response team discovers signs of a cybersecurity incident through automated systems, manual detection methods, or reports.

Analyzing the incident and improving procedures is the goal of the "lessons learned" phase, where organizations learn from the incident and make necessary changes to prevent future incidents.

q_incident_resp_containment_03_secp8

What is the primary goal of the containment phase of cybersecurity incident management during an incident response lifecycle? (Select two.)

Answers:

Remove all traces of the incident from affected systems.

Analyze the incident and responses to identify whether procedures or systems could be improved.

***Limit the immediate impact of the incident while securing data and notifying stakeholders.**

***Notify stakeholders and identify other reporting requirements.**

Reintegrate the system into the business process it supports with the cause of the incident eradicated.

Explanation:

Containment focuses on:

Limiting immediate impact of the incident from spreading further and minimizing its impact on both data and business operations.

The necessity of notifying stakeholders and identifying other reporting requirements.

The eradication phase involves removing the cause of the incident and restoring affected systems to a secure state.

The lessons learned phase involves analyzing the incident and responding to identify whether procedures or systems could be improved.

The recovery phase involves reintegrating the system into the business process it supports with the cause of the incident eradicated.

q_incident_resp_corporate_espionage_secp8

You are a cybersecurity analyst at a tech startup. Recently, you've noticed an unusual pattern of data access requests from a competitor's IP address. The requests are specifically targeting your company's proprietary algorithms and customer databases.

Based on this information, which type of security incident is MOST likely occurring?

Answers:

Employee errors

Unauthorized act by an employee

External intrusion attempts

Virus and harmful code

Corporate espionage

Explanation:

Unethical gathering of competitive information (or corporate espionage) is the correct answer. The scenario describes a deliberate attempt from a competitor to access proprietary information, which is characteristic of corporate espionage.

Employee errors is incorrect because the scenario describes a deliberate attempt to access proprietary information, not an unintentional action by an employee that causes damage or leaves network systems vulnerable to attack.

Unauthorized act by an employee is incorrect because the source of the data access requests is from a competitor's IP address, which suggests that the threat is external, not internal.

External intrusion attempts is incorrect because while the data access requests are coming from an external source, the specific targeting of proprietary algorithms and customer databases suggests a motive beyond a general intrusion attempt.

Virus and harmful code attacks is incorrect because the scenario does not mention any signs of malicious code or software, such as system crashes, slow performance, or unexpected pop-ups, which are typically associated with virus and harmful code attacks.

q_incident_resp_external_intrusion_attempts_secp8

You are a cybersecurity analyst at a large corporation. You receive an alert from your intrusion detection system (IDS) indicating a sudden spike in network traffic and multiple failed login attempts on a server containing sensitive data.

The source IP addresses are from various foreign locations.

Based on this information, which type of security incident is MOST likely occurring?

Answers:

Employee errors

Unauthorized act by an employee

***External intrusion attempts**

Virus and harmful code attacks

Unethical gathering of competitive information

Explanation:

External intrusion attempts is the correct answer. The scenario describes a deliberate attempt from various foreign locations to gain unauthorized access to a server, which is characteristic of an external intrusion attempt.

Employee errors is incorrect because the scenario describes a deliberate attempt to gain unauthorized access to a server, not an unintentional action by an employee that causes damage or leaves network systems vulnerable to attack.

Unauthorized act by an employee is incorrect because the source IP addresses are from various foreign locations, which suggests that the threat is external, not internal.

Virus and harmful code attacks is incorrect because the scenario does not mention any signs of malicious code or software, such as system crashes, slow performance, or unexpected pop-ups, which are typically associated with virus and harmful code attacks.

Unethical gathering of competitive information is incorrect because the scenario does not provide any information suggesting that the goal of the intrusion attempts is to obtain proprietary information for competitive advantage or client theft.

q_incident_resp_incident_secp8

What is the BEST definition of a security incident?

Answers:

Criminal activity

***Violation of a security policy**

Compromise of the CIA

Interruption of productivity

Explanation:

The best definition of a security incident is a violation of a security policy.

Criminal activity, compromise of the CIA, and productivity interruptions are all violations of security policy. They are specific examples of security incidents rather than a universal definition.

q_incident_resp_lessons_learned_secp8

The leader of the cybersecurity team for a major e-commerce company recently encountered a major data breach that led to the exposure of customer payment details. The team has now contained the breach and is moving toward the final phase of the incident response cycle.

What is the team's primary objective in this phase?

Answers:

Identify stakeholders and reporting requirements

Eradicate the cause of the incident

Restore the affected system to a secure state

***Analyze the incident and improve procedures or systems**

Explanation:

The final phase of the incident response lifecycle entails "lessons learned," which allows the organization to learn from the incident and make necessary changes to prevent similar incidents in the future.

During the containment phase in the incident response lifecycle, the incident response team identifies stakeholders and reporting requirements, limiting the scope of the incident and notifying relevant parties.

The eradication phase follows the containment phase. The primary goal is to eradicate the cause of the incident and involves removing the root cause and restoring affected systems.

The recovery phase in the incident response lifecycle aims to restore the affected system to a secure state and reintegrate it after containing and eradicating the incident.

q_incident_resp_process_secp8

An organization's computer incident response team (CIRT) receives an alert that shows possible malicious activity on a critical server within the network, and they initiate the CompTIA incident response process.

The team follows the incident response lifecycle to address the situation, which involves several key steps.

What order must the CIRT follow when performing the CompTIA incident response process?

Answers:

Preparation, analysis, isolation, containment, recovery

Detection, analysis, eradication, restoration, improvement

***Detection, analysis, containment, eradication, recovery**

Isolation, analysis, restoration, eradication, improvement

Explanation:

This sequence of detection, analysis, containment, eradication, and recovery represents the CompTIA incident response lifecycle steps. It ensures the CIRT properly addresses the incident while minimizing damage and potential recurrence.

Isolation is a step that is not part of the CompTIA incident response lifecycle. Additionally, isolation is often a containment technique rather than a standalone step.

q_isolate_contain_books_01_secp8

You would like to enhance your incident-response process and automate as much of it as possible.

Which of the following elements would you need to include? (Select two.)

Answers:

***Runbooks**

***Playbooks**

Whitelisting

Blacklisting

Quarantining

Explanation:

The correct answers are runbooks and playbooks. Runbooks are a condition-based series of protocols you can use to establish automated processes for security-incident response. A playbook is a checklist-style document that specifies the steps to be taken in response to a threat or incident. The steps are listed in the order to be performed. A playbook ensures a consistent approach to security issues.

Whitelisting allows an IT admin to control the applications, IP addresses, URLs, email addresses, etc. that are allowed onto the network.

Blacklisting is the opposite of whitelisting.

Quarantining is when antivirus software finds a malicious item and quarantines it in a special folder.

q_isolate_contain_books_02_secp8

The IT security team of a medium-sized company has identified various attack vectors and threat scenarios that could impact the organization. To enhance their incident response capabilities, the team is developing incident response playbooks.

Additionally, the team is researching external considerations such as legal and regulatory requirements, the potential involvement of law enforcement, and the need to notify affected customers in the event of a data breach.

What is the primary purpose of developing incident response playbooks in the company's cybersecurity strategy?

Answers:

***To provide predefined steps and procedures to respond effectively to cybersecurity incidents.**

To identify potential attack vectors and threat scenarios in the organization.

To ensure compliance with legal and regulatory requirements in case of a security breach.

To prevent cybersecurity incidents from occurring in the company's IT infrastructure.

Explanation:

The primary purpose of developing incident response playbooks is to provide predefined steps and procedures to respond effectively to cybersecurity incidents. Playbooks outline the necessary actions, roles, and responsibilities to minimize the impact of security breaches and handle incidents in a structured manner.

Incident response playbooks involve identifying potential attack vectors and threat scenarios, but the primary focus is establishing a response plan.

Although incident response playbooks address legal and regulatory requirements, the main goal is to outline the response procedures, not solely compliance measures.

Incident response playbooks are for responding to cybersecurity incidents after they occur, not to prevent them proactively. Preventive measures are usually part of a separate cybersecurity strategy.

q_isolate_contain_containment_secp8

You have detected and identified a security event. What is the first step you should complete?

Answers:

***Containment**

Isolation

Segmentation

Playbook

Explanation:

You would choose containment. Containment is the first step to complete after an event has been detected and identified.

Isolation limits the ability of a compromised process or application to do more harm to the network or its assets.

Segmentation is a strategic network design. The concept is simple: keep the sections of a network separated so that malicious actors cannot pivot within a network.

Playbooks are part of an incident-response plan. Playbooks can automate responses.

q_isolate_contain_isolate_secp8

A cyber security analyst at a multinational corporation detects abnormal network activities that indicate a possible security breach. The analyst investigates and confirms that an unauthorized person has accessed sensitive customer information. The incident response team must act quickly to contain the breach and stop further data loss.

What should the initial responder do first?

Answers:

***Disconnect the affected server from the network to isolate it from the production environment.**

Notify law enforcement authorities about the incident for immediate action.

Restore affected systems from secure backups to eliminate the threat.

Initiate a threat hunting exercise to discover evidence of TTPs proactively.

Explanation:

The first responder's primary goal is to contain the incident. Isolating the affected server from the network prevents further communication with the attacker and protects other systems from potential compromise.

Notifying law enforcement might be necessary in certain situations, but the immediate focus should be on containment and minimizing the impact of the incident.

While restoring affected systems from backups is an important step in the recovery phase, it should occur after containment to ensure the team has neutralized the threat.

Threat hunting is a proactive approach to identifying potential threats before they become incidents. In this case, the team has already detected the incident, so immediate containment is the priority.

q_isolate_contain_isolation_secp8

You need to limit a compromised application from causing harm to other assets in your network.

Which strategy should you employ?

Answers:

***Isolation**

Segmentation

Containment

SOAR

Explanation:

The correct answer is isolation. Process isolation is one way to protect a network. It ensures that if a process is compromised, only the resources that are used by that process are at risk.

Segmentation is a strategic network design. The concept is simple-keep the sections of a network separated so that malicious actors cannot pivot within a network.

Containment is not a preemptive strategy. Containment is something you do after an event has occurred.

SOAR is a platform to compile security data generated by different security endpoints. This compiled information is then sent to a security analyst for further action.

q_isolate_contain_segmentation_01_secp8

You need to limit the impact of a security breach for a particular file server with sensitive company data.

Which strategy would you employ?

Answers:

***Segmentation**

Isolation

Containment

SOAR

Explanation:

The correct answer is segmentation. You can segment using VLANs, software-defined networks, switches, subnetting, or even physical segmentation.

Isolation limits the ability of a compromised process or application to do more harm to the network or its assets.

Containment is the first step after an event has been detected and identified. Segmentation is preventative.

SOAR is a platform to compile security data generated by different security endpoints.

q_isolate_contain_segmentation_02_secp8

The security manager of a multinational organization is on a mission to apply security principles to a newly planned regional office that will connect with its existing global infrastructure. This task aims to minimize the attack surface and construct suitable security zones.

While developing the network architecture for the new office, what primary security aspect must the manager prioritize to certify the efficiency of the security zones and reduce the organization's attack surface?

Answers:

Enabling ports

Increasing redundant network paths

Setting up Single Sign-on (SSO)

***Implementing network segmentation**

Explanation:

Network segmentation involves dividing a network into smaller parts, creating distinct security zones. Network segmentation limits an attacker's ability to move laterally within a network, thereby minimizing the attack surface.

Enabling more ports unnecessarily or without adequate security measures increases the potential entry points for malicious actors, thereby enlarging the attack surface rather than minimizing it.

While redundancy increases network availability, it does not directly contribute to reducing the attack surface or defining security zones.

While SSO can enhance user experience and streamline access management, it does not directly minimize the attack surface or contribute to defining security zones.

q_isolate_contain_segmentation_03_secp8

A distribution company bidding on a national contract must demonstrate that its networks are secure and response times are adequate to stop attacks from reaching the client company.

What can support the company in meeting this requirement?

Answers:

***Segmentation**

Isolation

Hardening

Patch management

Explanation:

A segmented network divides systems into separate segments or subnets, each with distinct security controls and access permissions. This type of segmentation significantly complicates an attacker's work, giving an organization more time to detect and respond.

Isolation segregates individual devices within a network to limit their interaction. While isolation can help protect the network, segmentation provides better protection.

Hardening is the process of making an operating system or application more secure. It does not directly affect the network.

Patch management is a process for reviewing, scheduling, or automatically installing patches. Patch management protects devices, not the network.

q_isolate_contain_soar_secp8

As a security analyst, you are looking for a platform to compile all your security data generated by different endpoints.

Which tool would you use?

Answers:

***SOAR**

MDM

MAM

GDPR

Explanation:

The correct answer is SOAR (Security Orchestration, Automation, and Response). This compiled information is sent to a security analyst for further action. SOAR frees an analyst from constantly receiving security alerts as they are generated. Analysts can use parameters to automate solutions for security incidents that meet certain criteria.

An MDM is for managing mobile devices. It is not for all endpoints.

An MAM allows you to manage mobile apps on all sorts of devices, but it does not allow you to compile endpoint data.

GDPR (General Data Protection Regulation) is a framework in the EU for data protection and privacy.

9.2 Log Management

As you study this section, answer the following questions:

- What does a security information and event management (SIEM) system do?
- Why are trends important for network management?
- What part does event correlation play in a SIEM?
- How do IT security teams use alerts?

In this section, you will learn to:

- Save captured files with Wireshark.
- Use Elasticsearch, Logstash, Kibana.
- Use NetworkMiner
- Configure remote logging on Linux
- Log events on pfSense.

Key terms for this section include the following:

Term	Definition

SIEM	A software tool used to compile and examine multiple data points gathered from across a network.
Sensor	A device that gathers data from a device or system. It provides the collected data to a monitoring system.
Trend	Patterns of activity discovered and reported to the SIEM.
Sensitivity	Customized threshold for sensor data that is sent to the SIEM.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Monitoring 3.2 Given a scenario, apply security principles to secure enterprise infrastructure. Infrastructure considerations Intrusion prevention system (IPS)/intrusion detection system (IDS) Sensors 4.1 Given a scenario, apply common security techniques to computing resources. Secure baselines Establish 4.3 Explain various activities associated with vulnerability management. Identification methods Vulnerability scan Analysis Common Vulnerability Enumeration (CVE) 4.4 Explain security alerting and monitoring concepts and tools. Activities

	Log aggregation Alerting Tools Security information and event management (SIEM) NetFlow Vulnerability scanners 4.9 Given a scenario, use data sources to support an investigation. Log data Firewall logs Application logs Endpoint logs OS-specific security logs IPS/IDS logs Network logs Metadata Data sources Dashboards Packet captures
TestOut Security Pro	5.1 Implement Logging and Auditing Implement Logging and Auditing 5.1.2 Enable Device Logs 5.2 Assessment techniques 5.2.1 Implement intrusion detection 5.2.3 Scan for vulnerabilities

9.2.1 Security Information and Event Management (Lesson Video)

Transcript:

In this video, we'll discuss Security Information and Event Management, or SIEM, which is a tool used to compile and examine multiple data points gathered from across a network. We'll also explore log management.

Monitoring a network requires experience and solid tools. One common network security tool is a scanner that can identify vulnerabilities and recommend remediation steps. The scan delivers output information to the IT administrators via the SIEM dashboard. The interval between scans is set by the IT department. This tool also scans servers, firewalls, switches, software programs, and even security cameras and wireless access points.
There are many versions of SIEMs. Each one has different features and benefits, but all SIEMs have several features in common. One of these is the dashboard. These are generally customizable information screens that show real-time security and network information. This allows the IT security team to monitor events as they occur on the network.
Sensors play a vital role in monitoring and securing a network. These sensors are set up at critical endpoints, services, and other vulnerable locations. They're programmed to send customized alerts to the SEIM if certain parameters are reached or exceeded.
Before sensors are deployed, the IT security team sets their sensitivity. The benefit to variable sensitivity settings is the ability to customize the data that's sent to the SIEM. Not every company has the same needs, and that's what makes sensor-sensitivity customization so beneficial.
Trends are patterns of activity discovered and reported to the SEIM. This is how baselines are established. These trends help security analysts decide if reported activity is normal or outside of the baseline. Trends that don't fit previously recorded ones can be investigated. As the IT security team investigates and documents these trends, it becomes easier for them to quickly spot an anomaly that may signal a security concern.
Alerts are the SIEMs' way of letting the IT team know that a pre-established parameter has been contravened. The alert is intended to get the attention of the IT person who's monitoring the network. A best practice in this area is 24-hour monitoring. This means that weekends, holidays, and early hours are all filled. Hackers don't keep normal hours, and network equipment can break at the most inconvenient times!
Event correlation is a critical part of using a SIEM solution. The software gathers data from log files, system applications, network appliances, and other endpoints in order to analyze it. This work is tedious, and people are inefficient at it. That's why the event-correlation feature is valuable. Not only does it gather data, but it analyzes and compares known malicious behavior against the aggregate data so that events aren't missed.
That's it for this lesson. In this lesson, we learned about SIEMs and the features that make them a critical network component. These include customizable sensors and their placement. Trends help IT teams to establish baselines or norms for their network. Alerts provide critical information to the network monitor so that appropriate action can be taken. Event correlation automates a very laborious process and analyzes and compares aggregate data to known security behaviors and events, ensuring that nothing gets by undetected. All this is delivered to the IT team via a customizable dashboard for easy examination.

9.2.2 Log Management (Lesson Video)

Transcript:

In this video, we'll explore log categories, specific logs you should know, and open-source tools that are used to aid IT security teams.

Every network generates dozens and dozens of logs. Network logs tell us what's coming into and leaving our network. Every network appliance and almost every application produces logs which can be used for a variety of reasons. But more often than not, we use logs for network security.
System logs are produced by an operating system. These logs contain all the information that pertains to that OS like updates, errors, failures, and other system occurrences. This includes information for client computers and servers, which gives IT admins a way to investigate events on individual machines that may interconnect with other machines on the network.
Most applications produce some type of event logging. These logs show application access, crashes, updates, and any other relevant information which could be valuable in determining root-cause analysis. The application may be crashing or not performing correctly, and this could be tied to suspicious activity that may indicate malicious intent.
There are several logs that would fall under the security category. There are application-security logs, event-security logs, and security logs for specialty applications like IDS/IPS, endpoints, firewalls, routers, and switches. Also, logs for security cameras and wireless or physical access points are included under the security log umbrella.
There's no doubt that web server logs are one of the most tedious of all logs to parse. But web servers can be prime targets for hackers, so it's important to know who's interacting with your server and what they're attempting to do. Most web engines like IIS, Tomcat, Web Sphere, and NGINX have some level of server logging. These logs can tell you

exactly when users log onto your site and what their location is. They also give you some information on attempted attacks.
Domain Name System, or DNS, has been around for a long time. When DNS was designed, network security wasn't a priority. Over time, malicious actors started using DNS-targeted attacks. These attacks have the potential to be disruptive and quite expensive. With DNS logging, you can track updates and choose to approve or deny them. DNS also produces query logs that detail which requests are being handled by which instance. Rate limiting is another valuable tool that limits response rate. Analyze these logs to see when rate limiting was used and for what purpose. Client IP, record requests, flags, and other metadata can be included in these logs.
Dump files are created when an application, OS, or other computer function stops abruptly. The information that's stored in memory at the time is dropped into a file for later analysis. These files help IT admins perform root-cause analysis because they provide the state that the application was in when it crashed, error codes, and other clues as to what happened previous to the application failure. They can also give clues as to the crash's origin. This could be something as commonplace as a bad driver or hardware component, or it may prove, unfortunately, to be the result of a malicious act.
Authentication logs are vital to a network's security. Authentication servers may be Active Directory-based or OpenLDAP depending on your network structure. It's critical to know who may be poking around your network, so token requests, authentication failures, or failed logins on expired accounts are all stored on these authentication logs for you to view.
Voice over Internet Protocol, or VoIP, has become a common network application. With a high implementation rate comes attention from malicious actors. As with any network application, there are vulnerabilities that can be leveraged, so in order to defend it there needs to be a way to access information about what's happening at any given time.
Session Initial Protocol, or SIP, is the standard in VoIP calls. The key to tracking attacks against a VoIP system is understanding SIP and being able to parse its logs. These logs contain key information about where a call was initiated and what the communication's intent was. These facts help the IT security team create a stronger SIP security posture.
Syslog is short for System Logging Protocol. This protocol sends system logs and event messages to a server designated by the system administrator. It collects logs from various appliances and sends them to the syslog server where they can be reviewed and analyzed.
Rsyslog is an open-source tool created for use in Linux networks. It stands for rocket-fast system-log processing. It gets its name because of its ability to send a million messages per second to a local server. This tool's benefit is its diversity. It's capable of multi-threading by leveraging multiple security protocols like TCP, TLS, and others. It also allows for output-format customization.
Syslog-ng is a robust log-aggregating software for multiple platforms, including Windows. This tool increases the quality of the log data that's sent to your SIEM. It also facilitates lightning-fast log searches by using full-text queries and collects logs without the installation of server agents.
Journactl is a Linux tool that gathers the logs produced by systemd, a system that's the basis for many Linux components. This command is used in Bash to parse logs that've been collected by systemd. The results are presented in the syslog format and are ordered oldest to newest by default. This can be changed by using the â€“r flag. Each line shows the date, server hostname, process name, and any messages. If you're more comfortable using a command line tool, this is for you. Because it's a CLI tool, there are many key commands at your disposal to get you your logs quickly.
Nxlog is an open-source log-collector application. It uses log-collector agents to gather and send log data to a log server, which can itself be set up using nxlog. This application is available for both Windows and Linux. The Community edition supports multiple SIEM applications and works with Windows Event Viewer and syslog.
That's it for this lesson. In this lesson, we learned about different log categories like network logs, security logs, and application logs. We also learned about specific logs and how you can use them for better security. Finally, we learned about open-source tools that assist you in collecting and organizing log data and metadata. Understanding logs is truly the key to better security.

9.2.3 SIEM and Log Management Facts

This lesson covers the following topics:

- Security information and event management

Security Information and Event Management

A security information and event management (SIEM) system combines security information management (SIM) and security event management (SEM) functions into one security management system.

Security information and event management tools compile and examine multiple data points gathered across a network. The following table describes SIEM components.

Component	Description
Vulnerability scan output	Monitoring a network requires experience and solid tools. One tool standard to network security is a scanner that can identify vulnerabilities and recommend remediation steps. This tool scans servers, firewalls, switches, software programs, security cameras, and wireless access points. The scan delivers the output to IT admins via the SIEM dashboard. The interval between scans is set by the IT department.
SIEM dashboards	The dashboard is a common component of all SIEM systems. The dashboard consists of customizable screens showing real-time security and network information. The information in real-time allows the IT security team to monitor and respond to events on the network effectively .
Sensors	Sensors are a vital part of monitoring and securing a network. Sensors are set up at critical endpoints, services, and other vulnerable locations. These sensors are programmed to send customized alerts to the SEIM if specific parameters are not within the acceptable range.
Sensitivity	The IT security team sets the sensitivity level when the sensors are deployed. The benefit of variable sensitivity settings is the ability to customize the data sent to the SIEM. Not every organization will have the same needs in network monitoring.
Trends	Trends are patterns of activity discovered and reported to the SIEM. This is how baselines are established. Trends help security analysts decide whether reported activity is normal or outside the baseline. The security group can investigate trends that do not fit previously recorded information. As the IT security team investigates and documents these trends, it becomes easier for the team to spot a trend that may signal a security event quickly.
Alerts	Alerts are the SIEM's way of informing the IT team that a pre-established parameter is not within the acceptable range. The alert is intended to get the attention of the IT person or persons monitoring the network. A best practice in this area is 24-hour monitoring.
Correlation	Event correlation is a critical SIEM component. The software gathers data from log files, system applications, network appliances, etc., and analyzes it. This work is tedious; people are inefficient at it. That's why the event correlation feature is valuable. Not only does it gather the data, but it analyzes and compares known malicious behavior against the aggregated data, increasing the chances of the discovery of security events.

9.2.4 Monitoring Data and Metadata (Lesson Video)

Transcript:

In this lesson, we'll cover the use of bandwidth monitors and metadata from emails, mobile devices, web traffic, and files. We'll also talk about using netflow/sflow echo and Ipfix. Let's get started.

Bandwidth monitors are a type of application that help network admins understand bandwidth usage. The first order of business with these applications is to establish a baseline. The longer a monitor runs, the more data points are created.

When a substantial number of data points are created, a normal usage becomes apparent. Normal bandwidth usage is relative and varies by hours in the day, days of the week, and even weeks within the year. A baseline provides something concrete to compare against current usage or even suspect bandwidth usage.
There are many bandwidth monitoring applications available. There are cloud-based apps, on-premise apps, open source, and paid. Each one looks and functions differently, but each has the same goal, which is to allow easy access to bandwidth monitoring. The key is to learn how to establish a monitoring schedule and how to use the dashboard.
Here, we have some screenshots of different pages within a dashboard. As you can see, this graphic is showing bandwidth usage be the hour and below usage per day aggregated over time. This is the baseline that suspect usage is compared against. The second graphic shows the last hour's usage and the usage for a user-specified time frame. This allows for deeper examination of suspect bandwidth usage.
Email is a great tool that almost everyone uses to communicate. It's also the avenue for the majority of malicious network breaches. Fortunately, email provides metadata so it can be traced. All emails come with a header that contains information about both the sender and recipient. Parts of the headers can be spoofed to give investigators false information. The good news is that there are security devices that put X-headers throughout an emails' headers. These provide the originating email account and IP address, not the spoofed one.
Communications sent via mobile devices are common today. They come from tablets, laptops, smart phones, smart watches, and any other portable device that connects to the internet. These devices send emails and text messages and use apps to allow data and photo sharing. All this data produces metadata that can be used to identify people, places, times, and even deleted data. Pictures can be time stamped and geolocation stamped. Much of this metadata also reveals the origination of the data and the sender.
Websites produce many types of metadata. In fact, the metadata on a user's machine versus the server can be very different. The data on the opposite side of the transmission can help fill in gaps and corroborate findings on the opposing machine. Metadata includes IP addresses, user requests, user downloads, time spent on the site, and even attempts to gain unauthorized access. Web metadata also includes cookies, browser history, and even cached pages. Many times, malicious actors will attempt to obfuscate their real metadata. But the good news is that there are ways of finding the real metadata, especially for trained forensic investigators.
Files produce many types of metadata. The first kind is File Creation (date/time). The File Creation data is the first time the file was written to the storage media it's currently on. This means that the file can be created in a different place and then moved or copied to a new location.
Last written refers to the last time a file was saved for any reason. It could prove that the file was copied from a different location or that the file was altered. Last access is any time a file is touched. When combined with file creation metadata on a user's machine, it can establish the probability that the file was copied from one machine to another. It also introduces the idea that a third device is involved in data copy process. Once the third device is found, it makes obtaining answers much easier.
Network admins are always looking for a way to look at what's happening inside their network. Netflow is a session sampling protocol. This protocol works at Layers 2 through 4. It can exam each data flow that comes through or be set to sample sessions at certain intervals. If you want to sample packets in a broader layer range, then sFlow is your answer. This protocol works on Layers 2 through 7. Unlike Netflow, sFlow examines packets and can only be used in sampling mode. This is stateless packet sampling that provides information efficiently.
IPFIX integrates data that normally goes to Syslog or SNMP information directly in the IPFIX packet, eliminating thee additional services collecting data from each network device. IPFIX has provisions for fields that are variable-length, meaning no ID number restrictions. It came about because of the need for a standardized protocol for internal protocol flows. This data comes from routers, servers, and other network appliances that are mediation systems. The data is formatted and sent to an exporter and then on to a collector.
IPFIX, like NetFlow, looks at flow and the number of packets being sent and received during a given session.
That's it for this lesson. In this lesson, we talked about the different ways metadata is produced. We covered some of the pitfalls of metadata as well as some of the ways to overcome them. And we discussed creating a baseline using network bandwidth monitors. These monitors can alert us to abnormal activity on our network.

9.2.5 Saving Captured Files with Wireshark (Demo Video)

Transcript:

In this demo, we'll show you how to capture network packets. There are times when you might want to capture packets so you can analyze them later. Captured packets can be used by an analyst to profile an application's network traffic or to examine a protocol in more detail.

The two most popular tools to capture packets are Wireshark and TCPDump. Both Wireshark and TCPDump can be used with a variety of operating systems but for this demo we will use Security Onion.
Security Onion is usually set up with a monitor port that captures all packets that it sees. The packets are typically used with tools like Zeek and Snort. This interface can also be used by an analyst for ad-hoc captures.
There are two capture tools in Security Onion for ad-hoc captures. First, we will look at Wireshark. Wireshark is a graphical tool that allows packet capture, but is also an analysis tool. Because Wireshark requires root permissions to capture the packets, we must run Wireshark with elevated permissions.
To do this, go to Applications > Utilities > Terminal. At the command prompt type â€"Ëœsudo dpkg-reconfigure wireshark-common'. You are asked you if you want to allow non-superusers to be able to capture packets. Choose Yes.
Next, run â€"Ëœsudo usermod -a -G wireshark administrator'. This gives the administrative user rights to run Wireshark by adding it to the Wireshark group.
If your account on Security Onion has a different name, use that instead of administrator in the command. Once done, go to the power icon. Then, go down to the other power icon. Choose to restart.
Now the system has rebooted. After logging back into Security Onion, we can start to use Wireshark. We open it by going to Applications > Internet > Wireshark.
To set up a capture, select the interface on Security Onion that is set as the monitor port. In this instance, it is interface enp0s8. After selecting the interface, you can restart the capture by clicking the Shark Fin in the top left of the menu bar. By default, the captured packets will scroll by on the screen.
When we are done capturing, we can press the red stop button. At this point, we can analyze the captured packets as we would any other capture that has been given to us. We can then save that file as a PCAP file for later analysis. We're not going to save it here, but you can see we have the option.
Another way that we can capture packets with Security Onion is to use the command-line tool tcpdump. Let's open a new Terminal session and enter the command â€"Ëœsudo tcpdump -D' to list the possible interfaces that we can capture on. Note that enp0s8 is number 10 on the list.
To capture, run the command â€"Ëœsudo tcpdump -i 10 -w testout.pcap'. This will capture the packets on enp0s8 and write them to a file called testout.pcap. Press CTRL-C to stop the capture.
Now let's print the file to the screen using â€"Ëœtcpdump -r testout.pcap'. Here you can see the output of the file.
We can open this PCAP file in a tool like Wireshark or NetworkMiner. Let's open it in Wireshark. We type, â€"Ëœwireshark testout.pcap' and press Enter. After a second or two the PCAP file is loaded into Wireshark and we can use it to further analyze the packet capture.
That's it for this demo. In this demo we used Wireshark and TCPdump to capture packets and saved them to a PCAP file.

9.2.6 Use Elasticsearch Logstash Kibana (Demo Video)

Transcript:

In this demo, we use the Elasticsearch Logstash Kibana (ELK) stack to store and search security logs created by other tools in Security Onion such as Zeek. We'll use Kibana to review sample logs.

Security Onion is a free and open source Linux distribution for threat hunting, enterprise security monitoring, and log management. It includes Elasticsearch, Logstash, Kibana, Snort, Suricata, Zeek (formerly known as Bro), Wazuh, Sguil, Squert, CyberChef, NetworkMiner, and many other security tools.
First, we click the Kibana link on the Security Onion desktop. By default, Security Onion uses a self-signed TLS certificate. We tell Chromium to allow us to proceed by clicking Advanced and then proceed. On a production system, it would be advisable to install a valid TLS certificate and use the fully qualified name instead of localhost.
The username and password for Security Onion are set during the initial setup. In this case, we set up a user in the Security Operations Center (SOC). We'll login as that user.
After logging in, Kibana defaults to the dashboard page. This could be used as a dashboard for a SOC or as the starting point for a threat hunter. In this case, we want to look at the Network Intrusion Detection System (NIDS) logs, so we click NIDS to drill down.

Here we notice a classification of Attempted Administrator Privilege Gain that we want to look at further. To do that, we hover on that line and click the magnifying glass with the plus sign. This adds it as a filter. To keep the filter as we pivot to other parts of Kibana, we click Actions and pin the filter.
Next, we click Discover to see the logs that match the filter. Notice how the filter has stayed with us because we pinned it. Now we can see each log entry that matched our filter. Notice that the timestamp and other information about the alert is listed.
You can view more information for an event by clicking the arrow to the left of the time stamp. From the description, we can also search for more information about the signature listed. We do this by highlighting it, right-clicking, and choosing to search for it using Google.
Some signatures are based on Common Vulnerabilities and Exposures (CVEs). CVEs describe potential security issues with certain software or hardware. They provide a common language to evaluate the risk posed. By typing CVE into the search field, you can focus the results on signatures that are tied to a CVE. Researching the CVE can help you determine whether the attempt against the asset could be successful.
Let's look at one more example. But first, let's clear our pinned criteria by going to Actions and clicking Remove. We also need to remove the search term CVE. Once this is done, we'll go back to the dashboard.
Under Zeek Hunting, click HTTP to list alerts relating only to the HTTP protocol. Now we can look at the events based on the HTTP status messages and the methods used. Using the same technique with the magnifying glass as before, let's drill into the Forbidden messages.
Again, we want to pin the filter so that it stays with us as we move through Kibana. Notice that this time we are using a different way to pin the filter. This method allows you to pin or unpin individual filters instead of all filters.
In the details of one of the events, we can see the Uniform Resource Identifier (URI) that the attacker tried to access. We can also see the user agent of the attacker. In this case, our attacker didn't mask the fact that a common tool for finding website vulnerabilities called Nikto was being used.
That's it for this demo. In this demo we went over a few of the ways the power of Elasticsearch can be harnessed to help the security professional.

9.2.7 Use NetworkMiner (Demo Video)

Transcript:

NetworkMiner is a Network Forensic Analysis Tool. It is able to take a PCAP file and analyze it for clues about the hosts and protocols on the network at the time of the capture.

To open NetworkMiner in Security Onion, go to Applications, Other and then NetworkMiner. Once it opens, go to file open and then choose the pcap file that you want to analyze. NetworkMiner will then automatically analyze the file and present the information in a series of tabs.
The first tab is the hosts tab. This tab will list all of the unique hosts by IP addresses that were found in the PCAP file. Each host can be opened by clicking on the plus sign next to it revealing the information about the host that NetworkMiner knows. For example, if I open 172.28.24.3 I will get it's IP, MAC Address, information about the number of packets it sent and received, and any details about the host. In this case, if I click on the Host Details, I will see the User-Agent string of the browser the host used.
In the next tab, you will find the files that were transferred between hosts during the packet capture. Right-clicking on a file will allow you to open the file or calculate the file's hash. For this capture, I created a fake virus using the EICAR test string. This string when placed in a file will be detected as a virus by most vendors. I can choose to open the folder where the virus.exe is stored and then open it using gedit to show the EICAR string.
I can also use the file hash feature to compare the file to known bad file hashes using tools like VirusTotal. First right-click on the file and choose Calculate MD5/SHA1/SHA256 hash. Next highlight the hash you want to compare and press CTRL+C to copy it to the clipboard. In a web browser, open VirusTotal.com and click on the Search link. Then paste the hash into the search box and press enter. This will then compare the hash against known malicious files. In this case, it will be an EICAR test file that most antivirus manufacturers will mark as a virus.
Another tab of interest is the credentials tab. Here any clear text credentials like telnet, FTP, or HTTP will be shown. In this capture, there was an FTP session that we have the credentials for.
The sessions tab shows the unique conversations between hosts.
Any DNS queries and responses that are captured will be decoded in the DNS tab.
The parameters tab shows many potential key-value pairs that may have important information.

Finally, NetworkMiner provides the ability to search a PCAP file for certain keywords. You can do this by clicking on Keywords. Next add a keyword and follow the instruction to reload the case file. The display will now show all of the packets that include the keyword.
That's it for this demo. In this demo we used NetworMiner to view the contents of a captured PCAP file.

9.2.8 Configuring Remote Logging on Linux (Demo Video)

Transcript:

There are many aspects of the syslog daemon that you can modify to customize how your log files are configured. You could have warning messages going into one file, error messages going into another, or separate them based on program. But one of the cool things I think the syslog daemon can do is log to a remote host. This basically allows us to write our logs not only to our local system but also to a log host somewhere else. This is a great benefit for the administrator. You can set up a log host in your network somewhere and all the logs from all the systems you support go into that log host. If somebody's having a problem, instead of having to use SSH in their system to look at their log files, you can have one central location to view them. This can be very helpful in keeping history and tracking your log files. Syslog servers are also very helpful when there has been an attack on your network.

That's what we're going to do here. We're going to configure the syslog daemon to log to a remote host. I have two different Linux systems running. I have a RedHat system running here that will serve as my log host and I have a CentOS system running here that will serve as my log client. The log messages from the CentOS system are going to be saved on our syslog server which happens to be our Redhat system. Keep in mind that different Linux distributions may be slightly different. But the same concepts apply.
Let's configure the log host first. The first thing we need to do is check to see if the rsyslog daemon is running. Type â€˜systemctl status rsyslog'. As you can see everything appear to be in order. We need to change to our root user account, so I'll do a 'su- root' command and enter the password. We're going to edit the configuration file with the â€˜vi /etc/rsyslog.conf' command. As we scroll down, we're going to uncomment some modules. These are the imudp module and the imtcp module. These modules enable the syslog daemon to listen for incoming syslog messages.
Down at the bottom in the rules area we have a template we're going to use for our remote logging. This template isn't here by default so it has to be added. This allows the remote logs to be placed in their own folder by host name and program name. If you don't set up a template, all syslog messages from remote hosts will go in the /var/log/messages of the syslog server. We're going to uncomment this by removing the pound symbols. Let's save it by typing â€˜:wq!'.
For these changes to take effect, we must restart the rsyslog daemon by typing â€˜systemctl restart rsyslog'. Since there will be incoming traffic, we need to modify the firewall to accept incoming messages on port 514.
To do so, type â€˜firewall-cmd --permanent --add-port=514/udp'. When you press Enter you see that it was a success. Now we do the same thing with the TCP protocol with "arrow up" and remove UDP for TCP. The changes won't be active until we reload the firewall with the â€˜firewall-cmd --reload' command.
I'm going to do a netstat to make sure the syslog daemon is listening on port 514.
Type â€˜netstat -tulnp | grep "rsyslo"' and press Enter. This shows us that rsyslogd has port 514 open for UPD and TCP.
We're going to venture over to our CentOS client server that's going to be sending syslog messages to our RedHat server. First, we check to make sure the rsyslog daemon is running by typing "systemctl status rsyslog". We're good to go.
Just like our syslog server, we're going to modify the configuration file for rsyslog. Let's type â€˜sudo vi /etc/rsyslog.conf'. Enter the password and press Enter. We're going to scroll all the way to the bottom to this configuration file.
Just so that I know what this is, I'm going to put a comment in there which is "#syslog server" and type â€˜*.* @@192.168.0.55:514'. The *.* is a wildcard that sends all syslog messages to the syslog server. The IP address listed is the IP of the syslog server and 514 is the port specified to use. We save this with â€˜:wq!' and Enter.
â€˜sudo systemctl restart rsyslog' allows the rsyslog daemon to grab the new settings we just edited.
Now this is the fun part. We will actually get to see a message go over to our syslog server from our CentOS client server. To write a test message, we type â€˜logger this is a test message' and press Enter. Let's use â€˜sudo tail -f /var/log/messages' to see the message locally. Now that we see the local message, let's go over to our syslog server with â€˜cd /var/log/centos-server1/'. I'm going to do a quick â€˜ll' to list what log files have already been written. Since we did a logger command under the TestOut user, we're going to tail that log file to look for our newly created test message with â€˜tail -f testout.log'. As you can see, it's the exact same message that was on our CentOS client server.

That's it for this demo. In this demonstration, we talked about how to configure a log host with Linux on a network. We first looked at the steps you need to complete in order to configure the system that's going to function as the log host to receive logging messages from another system. Then we looked at the log client and configured it to send its log messages not only to its own log files, but also to send a copy to our log host.

9.2.9 Logging Events on pfSense (Demo Video)

Transcript:

In this demo, we're going to spend a few minutes viewing log files on our pfSense security appliance. A log should act as a red flag that something is happeningâ€”potentially something bad. By reviewing your logs on a regular basis, you'll get an idea of the normal traffic on your device. In reality, no one likes to spend hours a day viewing log files. Typically, you would want to configure a syslog server so that all your logs from all devices go to one place to be consolidated for easier analysis.

To view logs on pfSense, we first need to go to Status and then down to System logs. Once we're in System logs, we see the General tab. Like I said, viewing logs isn't the most exciting thing to do, but it's necessary. Under the General tab we can see that we have a time stamp, a process, a PID or process ID, and a message about the log. Let's move on to Gateways.
Under Gateways, you can see that I only have one Gateway on this test system. Looks like my system is grabbing an IP for the WAN network interface. You might be thinking that if it's grabbing an IP from a WAN, shouldn't this be a public IP? That answer is yes, but I do have a test network set up and that network is connected to my regular LAN.
We also have our Routing logs here. Next to that I have my DNS Resolver logs. Finally, we have our Wireless logs. I don't have any Wi-Fi currently configured with this device, so there are no logs for our Wi-Fi.
I'll move over to my Firewall logs. This is generally where you might look for malicious attacks directed toward your network. You'll see information down here with more details. As I scroll down, you can see the different source IPs that triggered the log. This one here, 172.16.1.100, is from my DMZ trying to get out to the WAN.
Dynamic View shows us a bit less detail. Down here I have some WAN traffic on port 5353. As you first get a system set up, you might want to familiarize yourself with the different ports that your firewall is logging. Some ports might be perfectly normal while others might not be. I wasn't familiar with port 5353, but a quick web search told me it's for multicast DNS and is safe. So now I know what it is.
Summary View gives us a bunch of graphs that can be helpful to get a quick visual of things. Here I have my different interfaces. I have three in this deviceâ€”one for my LAN, one for the DMZ, and one connected for the WAN.
I have my protocols and it looks like most of my traffic is UDP.
Down here a little further, I can see the source IPs of what's been triggering the logs. All the 192.168 addresses are from the WAN interface and the 172.16 address is my DMZ.
I have the destination IPs in this next graph. I have my source ports next. Finally, I have destination ports. Here you can see UDP/53 listed. That is my DNS traffic.
So, it's good to get familiar with what your typical traffic looks like. This is called creating a baseline. This isn't covered in this demo, but it should be one of the first things you do when setting up new devices.
My next set of logs are DHCP logs. Here you can see who's getting IPs from the DHCP server. Not only can you see who's getting IPs, but you can see the DHCP acknowledgement, the DHCP requests, and down here you can see that DHCP renewed an IP for one of the clients. All of this is useful information if you're troubleshooting DHCP or need to see what devices are connecting to your network.
I had this device set up as a captive portal at one time so that we could see all the events that are related to it. As a quick review, a captive portal is a web page you're taken to, such as in a hotel or other public place, before you're given access to the internet. You typically must agree to the terms and conditions before being allowed to proceed. You might have to enter a password as well.
The next four tabsâ€”IPSec, PPP, VPN, and Load Balancerâ€”have no log files because I don't have any of those services running on this device. But I do have OpenVPN configured. Down here you can see all of those log files. I do have some NTP logs, or Network Time Protocol logs, here.
The last thing I want to look at is log settings. If you noticed as we were viewing logs, there were only fifty shown. Here is where we can change that if needs be. As I scroll down, you can see other settings that you can configure. You can even reset your logs.

Here at the bottom is where you can configure pfSense to send these logs to a syslog server. I'll check this box to enable it. When I do, I'm presented with some more settings specific to remote logging.
I can be specific about which interface I want to log. I can log all of them, or just one. I could just log my WAN events if that's all I'm concerned about.
I can choose to only have IPv4 logs or only have IPv6 logs sent. Here I would put the IP and port of the remote syslog server that's configured to receive those logs. I don't have a server set up for this demo, but if I did, this is where I would tell pfSense to send the logs to. The format would be something like 10.10.10.100, and it would be port 514. Port 514 is the port that pfSense uses by default to send logs to the syslog server.
Now I would need to tell pfSense what I want to send. I don't like information overload. I only want to send the logs that I actually need. So I might only want firewall events, DNS events, DHCP events, and VPN. In my case, that's OpenVPN. I would then click on Save and, if my syslog server is configured, it'll start to receive log files from my pfSense security appliance.
That's it for this demo. In this demo, we examined the logs on our pfSense security appliance. We viewed many of the different logs that can be collected. We then looked at settings and some things that we can configure. We ended by explaining how to send our logs to a syslog server.

9.2.10 Monitoring Data and Metadata Facts

This lesson covers the following topics:

- Log data
- Metadata
- Data analyzers

Log Data

Log data is a critical resource for investigating security incidents. As well as the log format, you must also consider the range of sources for log files and know how to determine the type of log file that best supports any given investigation scenario.

Event data is generated by processes running on network appliances and general computing hosts. The process typically writes its event data to a specific log file or database. Each event is comprised of message data and metadata:

- Event message data is the specific notification or alert the process raises, such as "Login failure" or "Firewall rule dropped traffic."
- Event metadata is the source and time of the event. The source might include a host or network address, a process name, and categorization/priority fields.

Accurate logging requires synchronization of each host to the same date, time value, and format. Ideally, each host should also be configured to use the same time zone or a "neutral" zone, such as universal coordinated time (UTC).

Windows hosts and applications can use Event Viewer format logging. Each event has a header reporting the source, level, user, timestamp, category, keywords, and hostname.

Syslog provides an open format, protocol, and server software for logging event messages. It is used by a vast range of host types. For example, syslog messages can be generated by switches, routers, firewalls, and UNIX or Linux servers and workstations.

A syslog message comprises a PRI code, a header, and a message part:

- The PRI code is calculated from the facility and severity level.

The header contains a timestamp, hostname, app name, process ID, and message ID fields.

The message part contains a tag showing the source process plus content. The format of the content is application-dependent. It might use space- or comma-delimited fields or name/value pairs.

Metadata

File metadata is stored as attributes. The file system tracks when a file was created, accessed, and modified. A file might be assigned a security attribute, marking it as read-only or a hidden or system file. The ACL attached to a file showing its permissions represents another attribute. Finally, the file may have extended attributes recording an author, copyright information, or tags for indexing/searching.

As metadata is uploaded to social media sites, they can reveal more information than the uploader intended. Metadata can include current location and time, which is added to media such as photos and videos.

Metadata is produced by almost all network activity. Server requests, applications, and email are examples of where metadata can be found. In the context of bandwidth monitors, metadata is used to investigate security-related concerns or incidents. The following table describes three types of metadata.

Type	Description
Email metadata	Email provides metadata that is used to trace email. All emails come with a header containing information about the sender and recipient. Parts of the headers can be spoofed, giving investigators false information. However, there are security devices that put X-headers throughout an email's header. These provide the originating email account and IP address, not the spoofed one.
Mobile metadata	Tablets, laptops, smartphones, smartwatches, and any other device that connects to the internet and can be moved around produces mobile metadata. These devices send emails, text messages, and use apps. All these produce metadata that can be used to identify people, places, times, and even deleted data. Pictures can be timestamped and geolocation stamped. Much of this metadata also reveals the origination of the data and the sender.
Web metadata	Websites produce many types of metadata. The metadata on a user's machine versus the server can differ greatly. The data on both sides of the transmission can help fill in gaps and corroborate findings. Metadata includes IP addresses, user requests, downloads, time spent on the site, and attempts to gain unauthorized access. Web metadata includes cookies, browser history, and cached pages. Many times, malicious actors will attempt to obfuscate their metadata. However, there are ways of finding the actual metadata, especially for trained forensic investigators.

Data Analyzers

Network admins should always look for a way to examine what is happening inside the network. There are several tools to help sift through the tremendous amounts of data generated by network activity. The following table describes some of these tools.

Tool	Description
NetFlow	NetFlow is a feature on Cisco routers. It works at layers 2 – 4. It can examine each data flow that comes through the network or be set to sample sessions at specific intervals.

Tool	Description
sFlow	sFlow is a packet sampling technology that works on layers 2 – 7. Unlike NetFlow, sFlow can only be used in sampling mode. This is a stateless packet sampling that provides information on various layers and does it quickly and efficiently.
IPfix	IPfix directly integrates data that usually goes to Syslog or SNMP. This eliminates additional services collecting data from each network device. IPfix has provisions for variable length fields, meaning there are no ID number restrictions. IPfix addresses the need for a standardized protocol for internal protocol flows. This data comes from routers, servers, and other network appliances that are mediation systems. The data is formatted, sent to an exporter, and then sent to a collector. IPfix, like NetFlow, looks at flow and the number of packets sent and received during a given session.

9.2.11 Practice Questions (Section Quiz)

q_siem_logmgmt_alert_secp8

Which of the following components are the SIEM's way of letting the IT team know that a pre-established parameter is not within the acceptable range?

Answers:

Sensors

Dashboard

Trends

***Alerts**

Explanation:

Alerts are the SIEM's way of letting the IT team know that a pre-established parameter is not within the acceptable range. An alert is intended to get the attention of the IT person monitoring the network. A best practice in this area is 24-hour monitoring.

Sensors are set up at critical endpoints, services, and other vulnerable locations. These sensors are programmed to send customized alerts to the SIEM if certain parameters are not within the acceptable range.

The dashboard consists of customizable information screens that show real-time security and network information.

Trends are patterns of activity discovered and reported to the SIEM.

q_siem_logmgmt_correlation_secp8

As a cybersecurity analyst, you are tasked with identifying a critical component of a Security Information and Event Management (SIEM) system that can analyze and compare known malicious behavior against aggregated data from log files, system applications, and network appliances.

Which component of the SIEM system would be MOST effective for this task?

Answers:

SIEM Dashboards

Alerts

Trends

***Correlation**

Explanation:

Correlation is the correct answer. Event correlation is a critical SIEM component. The software gathers data from log files, system applications, and network appliances and analyzes it. This work is tedious; people are inefficient at it. That's why the event correlation feature is valuable. Not only does it gather the data, but it analyzes and compares known malicious behavior against the aggregated data, increasing the chances of the discovery of security events.

While SIEM dashboards provide a visual representation of real-time security and network information, they do not analyze and compare known malicious behavior against aggregated data. They merely display the information gathered by other components of the SIEM system.

Alerts are the SIEM's way of informing the IT team that a pre-established parameter is not within the acceptable range. However, alerts themselves do not analyze and compare known malicious behavior against aggregated data. They are used to notify the team of potential issues.

Trends are patterns of activity discovered and reported to the SIEM. They help security analysts decide whether reported activity is normal or outside the baseline. However, trends themselves do not analyze and compare known malicious behavior against aggregated data. They are used to analyze the data collected by other components of the SIEM system.

q_siem_logmgmt_dashboard_secp8

As a cybersecurity analyst, you are tasked with implementing a Security Information and Event Management (SIEM) system that allows the IT security team to effectively monitor and respond to events on the network in real-time.

Which component of the SIEM system would be MOST critical for this task?

Answers:

Vulnerability scan output

Sensors

Trends

***SIEM dashboards**

Explanation:

The correct answer is SIEM dashboards. The dashboard is a common component of all SIEM systems. The dashboard consists of customizable screens showing real-time security and network information. The information in real-time allows the IT security team to effectively monitor and respond to events on the network.

While vulnerability scans are essential tools for identifying potential weaknesses in the network, they do not provide real-time monitoring or response capabilities. They provide a snapshot of the vulnerabilities present at a specific point in time, but do not provide continuous monitoring.

Sensors are a vital part of monitoring and securing a network. They are set up at critical endpoints, services, and other vulnerable locations and are programmed to send customized alerts to the SIEM system if specific parameters are not within the acceptable range. However, sensors themselves do not provide a real-time overview of the network events.

Trends are patterns of activity discovered and reported to the SIEM. They help security analysts decide whether reported activity is normal or outside the baseline. However, trends themselves do not provide real-time monitoring or response capabilities. They are used to analyze the data collected over a period of time.

q_siem_logmgmt_sensors_secp8

As a cybersecurity analyst, you are tasked with improving the security posture of your organization. You are considering the implementation of a Security Information and Event Management (SIEM) system.

Which component of the SIEM system would be MOST critical for monitoring and securing network endpoints, services, and other vulnerable locations?

Answers:

Vulnerability scan output

SIEM dashboards

***Sensors**

Trends

Explanation:

Sensors is the correct answer. Sensors are a vital part of monitoring and securing a network. They are set up at critical endpoints, services, and other vulnerable locations and are programmed to send customized alerts to the SIEM system if specific parameters are not within the acceptable range.

While vulnerability scans are essential tools for identifying potential weaknesses in the network, they are not the most critical component for monitoring and securing network endpoints, services, and other vulnerable locations. They provide a snapshot of the vulnerabilities present at a specific point in time, but do not provide continuous monitoring.

SIEM dashboards provide a visual representation of real-time security and network information. However, the dashboard itself does not monitor or secure network endpoints. It merely displays the information gathered by other components of the SIEM system.

Trends are patterns of activity discovered and reported to the SIEM. They help security analysts decide whether reported activity is normal or outside the baseline. However, trends themselves do not monitor or secure network endpoints. They are used to analyze the data collected by other components of the SIEM system.

q_siem_logmgmt_siem_secp8

Which tool or concept used in cybersecurity monitoring gives a condensed overview of information from various data sources for daily incident response tasks?

Answers:

***Security Information and Event Management (SIEM) tools**

Network-based vulnerability scanners

Log files generated by applications on hosts

Host-based intrusion detection systems

Explanation:

SIEM tools aggregate and correlate data from various sources, creating a summarized view of information through event dashboards. These dashboards support daily incident response tasks by providing a comprehensive snapshot of security events and indicators.

Network-based vulnerability scanners focus on identifying vulnerabilities in network devices and systems, but they do not provide summarized views of diverse data sources for incident response tasks.

Although logs created by applications on hosts are sources of data, they are not typically for providing condensed overviews for daily incident response duties.

Host-based intrusion detection systems monitor activities on a single host. They can generate alerts, but are not for aggregating and correlating data from diverse sources for summarized views.

q_mon_metadata_event_metadata_secp8

Which of the following BEST describes the role of event metadata in network security?

Answers:

It provides the specific notification or alert the process raises.

***It is the source and time of the event, which can include a host or network address, a process name, and categorization/priority fields.**

It is used to synchronize each host to the same date, time value, and format.

It is the data that is generated by processes running on network appliances and general computing hosts.

Explanation:

The source and time of the event is the correct answer. Event metadata provides context about the event, including its source and time. This can include a host or network address, a process name, and categorization/priority fields. This information is crucial for understanding and investigating security incidents.

The specific notification or alert the process raises is called event message data, not event metadata.

While synchronization of each host to the same date, time value, and format is important for accurate logging, this is not the role of event metadata.

The data generated by processes running on network appliances and general computing hosts is referred to as event data, which includes both event message data and event metadata.

q_mon_metadata_file_metadata_secp8

What kind of metadata is usually linked with files and includes information like creation date, access history, and security permissions?

Answers:

Web metadata

Email header metadata

Social media metadata

***File metadata**

Explanation:

File metadata encompasses attributes such as creation date, access history, modification details, security permissions, and extended attributes, offering insights into files stored on a system.

Web metadata involves headers exchanged between web clients and servers, encompassing details about the requested resource, data type, and authorization. It does not directly correlate with file attributes like creation date and security permissions.

Email header metadata comprises sender and recipient address details and information about servers engaged in email transmission. It pertains to email communication and does not relate to file attributes.

Social media metadata can encompass details such as the location and time when a user has uploaded media, like photos and videos. This metadata correlates with content uploaded to social media platforms.

q_mon_metadata_ipfix_secp8

You are a cybersecurity analyst tasked with investigating a security incident.

You need to analyze network traffic data that normally goes to Syslog or SNMP, and you also need a tool that can address the need for a standardized protocol for internal protocol flows. Additionally, you need to collect data from routers, servers, and other network appliances.

Which tool would be BEST for you to use?

Answers:

NetFlow

sFlow

***IPfix**

Web metadata

Explanation:

IPfix is the correct answer. IPfix directly integrates data that normally goes to Syslog or SNMP, eliminating additional services collecting data from each network device. IPfix addresses the need for a standardized protocol for internal protocol flows. This data comes from routers, servers, and other network appliances that are mediation systems. The data is formatted, sent to an exporter, and then sent to a collector. IPfix, like NetFlow, looks at flow and the number of packets being sent and received during a given session.

NetFlow is incorrect because while NetFlow is a feature on Cisco routers that can examine each data flow that comes through the network, it does not directly integrate data that normally goes to Syslog or SNMP, nor does it address the need for a standardized protocol for internal protocol flows.

sFlow is incorrect because while sFlow is a packet sampling technology that works on layers 2-7 of the stack, it does not directly integrate data that normally goes to Syslog or SNMP, nor does it address the need for a standardized protocol for internal protocol flows.

Web metadata is incorrect because while web metadata can provide valuable information about user behavior on websites, it is not a tool for analyzing network traffic data or for integrating data that normally goes to Syslog or SNMP. Web metadata includes information like IP addresses, user requests, user downloads, time spent on the site, and attempts to gain unauthorized access, but it does not address the needs specified in the question.

q_mon_metadata_syslog_message_secp8

In the context of a syslog message, which of the following components is calculated from the facility and severity level?

Answers:

Header

Message

***PRI code**

Timestamp

Explanation:

PRI code is the correct answer. The PRI code in a syslog message is calculated from the facility and severity level. The facility refers to the source of the message (like a hardware device, a protocol, or a module of the system software), and the severity level indicates how urgent or critical the message is.

The header of a syslog message contains timestamp, hostname, app name, process ID, and message ID fields. It does not include the PRI code.

The message part of a syslog message contains a tag showing the source process plus content. The format of the content is application-dependent. It does not include the PRI code.

The timestamp in a syslog message indicates the time when the event occurred. It is not calculated from the facility and severity level.

q_mon_metadata_web_metadata_secp8

You are a cybersecurity analyst investigating a potential data breach in your organization. You have identified a suspicious user who appears to have accessed sensitive information.

Which type of metadata would be MOST useful to determining the user's activities on your organization's internal web applications?

Answers:

Email metadata

Mobile metadata

File metadata

***Web metadata**

Explanation:

Web metadata is the correct answer. Web metadata can provide detailed information about a user's activities on web applications, including IP addresses, user requests, downloads, time spent on the site, and attempts to gain unauthorized access. This would be the most useful type of metadata for this investigation.

While email metadata can provide useful information about the sender and recipient of an email, it would not provide detailed information about a user's activities on web applications.

Mobile metadata can provide information about a user's activities on mobile devices, including emails, text messages, and app usage. However, it may not provide detailed information about a user's activities on specific web applications.

File metadata provides information about a file, such as when it was created, accessed, and modified. While this could potentially provide some insight into a user's activities, it would not provide detailed information about a user's activities on web applications.

q_mon_metadata_xheader_secp8

You are worried about email spoofing. What can be put throughout an email's header that provides the originating email account or IP address, and not a spoofed one?

Answers:

***X-headers**

Timestamp

Metadata

Data points

Explanation:

X-headers is the correct choice. You do this with security devices that are designed for this purpose. These devices put X-headers throughout an email's header and provide the originating email account and IP address, not the spoofed one.

Timestamps and metadata (of which timestamps are a part) do not provide an originating email account or IP address (spoofed or otherwise).

A data point is a unique fact such as income, wealth, age of an individual, and the number of dependents. Data points are not designed to provide an originating email account or IP address (spoofed or otherwise).

9.3 Digital Forensics

As you study this section, answer the following questions:

Why is a chain of custody important in an investigation?

What importance does a provable timeline of events play in admissibility of digital forensic evidence?

Why is it important to take a bit-by-bit copy of the logs?

How does the order of volatility help you decide what to secure and preserve first?

What is a digital forensic artifact?

How does provenance play a vital role in digital forensics?

In this section, you will learn to:

Create a forensic drive image with FTK, Guymager, and DC3DD.

Examine a forensic drive image with Autopsy.

The key terms for this section include:

Term	Definition
Legal hold	A process designed to preserve all relevant information when litigation is reasonably expected to occur. A formal notice sent out to all employees of a company when litigation is eminent. The notice instructs all employees to retain electronically stored information (ESI).
Chain of custody	A record of the handling of gathered evidence. This gives all parties involved confidence that no evidence tampering has occurred.
Hashing	A function that converts an arbitrary-length string input to a fixed-length string output.
Provenance	Provenance demonstrates that the digital evidence gathered came from the documented source of evidence and that it has not been tampered with.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	4.8 Explain appropriate incident response activities. Digital forensics Legal hold Chain of custody Acquisition Reporting Preservation E-discovery 4.9 Given a scenario, use data sources to support an investigation. Data sources Vulnerability scans Dashboards Packet captures

9.3.1 Forensic Documentation and Evidence (Lesson Video)

Transcript:

Digital forensic analysis is the art of revealing important information from computer systems and networks. Every piece of evidence can hold key information. From deleted files to timestamps, user activity, and unauthorized traffic, gathering and examining evidence from computer systems and networks can reveal critical insights. But how do we ensure the validity and integrity of this evidence?

Documentation plays a crucial role in collecting, preserving, and presenting valid digital proofs. Failure to maintain a thorough record can jeopardize the integrity of the evidence. It's important to understand that there are various processes and tools used to acquire different types of digital evidence from computer hosts and networks. By following strict protocols, these processes not only demonstrate how evidence is acquired but also establish that it's an accurate representation of the system at the time of the event.
Just like DNA or fingerprints, digital evidence is latent, meaning it can't be seen with the naked eye. It requires specialized machines and processes to interpret. Therefore, formal steps must be taken to ensure the admissibility of this evidence in court. Proper documentation is crucial in showing how the evidence was collected and analyzed without any tampering or bias.
This is where due process comes into play. Just as the law requires fairness in criminal convictions, forensic investigations must adhere to procedural safeguards to ensure fairness. Anyone involved in the investigation, from technicians to managers, must be aware of these processes to avoid compromising the integrity of the investigation. Defense lawyers will always look for any doubts or mistakes in the evidence or collection process.

When information becomes central to a court case, it's essential to preserve it. This concept, known as legal hold, entails suspending routine deletion of electronic or paper records and logs. Regulatory requirements, industry standards, or litigation notices from law enforcement or lawyers can trigger legal holds, leading to the seizure of computer systems as evidence. When information is subject to legal hold, computer systems may be taken as evidence, disrupting the network.

To maintain the integrity of the evidence, a chain of custody is established. Host devices and media from the crime scene are carefully labeled, bagged, and sealed using tamper-evident bags. Anti-static shielding is used to protect electronic media from damage. Each piece of evidence is documented on a chain of custody form, recording who collected it, who handled it afterward, what measures were taken for backup and analysis, and where it was stored. This ensures the evidence remains intact and untampered with. Finally, the collected evidence is stored in a secure facility. This not only includes access control but also environmental control to protect the electronic systems from damage.

By following these key elements—proper documentation, due process, legal hold, and chain of custody—digital forensic analysts can ensure the validity and credibility of the evidence they gather.

That's it for this lesson. In this lesson, we talked about forensic documentation and evidence. We reviewed the importance of documentation and due process. We discussed legal holds and the importance of the chain of custody for ensuring the integrity of evidence.

9.3.2 Forensic Acquisition of Data (Lesson Video)

Transcript:

A forensic investigator gathers evidence from many sources. In this lesson, we will discuss software and hardware sources of potential evidence. We will also discuss the order in which the evidence needs to be gathered.

The process of capturing volatile data follows the order of volatility. We need to preserve the most volatile data first and work our way down to data that is more persistent. If an attack is underway, your computer forensics response team is probably going to capture volatile data before trying to gather data from the hard disk or turning the system off.

The order of volatility is: RAM, Swap Files/PageFiles, Hard Drive, Remote Logs, Archived Data. These items must be investigated in this order so that potential evidence is not lost.

Each one of these items has its own challenges and potential dangers when acquiring forensic data. Let's look at tools and approaches to acquire and retain data from these items.

In a computer forensics investigation, the data on the hard disk drive is a key piece of evidence. A lot of the things that we do on a computer system are saved in some way on the hard disk drive, including virtual memory. A wealth of data is there.

In addition, information attached to deleted files may still be on the disk. Therefore, the hard drive itself is a goldmine of evidence for a prosecutor. Caution must be exercised when making a copy of the hard drive. A regular file-for-file copy is not good enough. It needs to be a sector-by-sector copy that includes data formerly deleted but still accessible.

RAM is the most volatile of all computer data storage. RAM is cleared when a computer is shutdown. Once gone, it cannot be recovered. Data in RAM can be copied as long as the system is running, but should be done only by someone with proper training. The data stored in RAM can have valuable information. Many times malware like worms, viruses and trojan horses are created as memory-resident only. This makes catching them difficult.

Swap files, or page files, are a virtual extension of RAM. An OS is designed so that if you are running low on RAM it can place not-in-use information into the swap or page file on the hard drive to be used later. An admin can determine how much space to allocate to page files. For the forensic investigator, this is another potential source of evidence. The page file data does not automatically delete at shutdown unless you change the default settings.

The OS is a virtual treasure trove of evidence. File systems like NTFS and Ext4 are the roadmap to where data is stored. There is also a registry which is a database that stores information about all the applications installed on a computer. Registry keys are folder-like objects that store application-specific
information for each application stored in the registry. The recycle bin is where deleted files are placed. Also the print spooler can be examined to see the print history from a computer.

In the last 30 years technology devices have changed dramatically. With the increase of digital devices there is an equal increase in devices that may require forensic examination. These devices contain all the evidence a forensic investigator needs. Each device, such as smart phone, tablet, laptop and smart watch all share common elements, namely RAM, CPU, logs and storage space. A trained investigator must be familiar with all platforms.

Firmware is the basic level of software that controls some hardware. Firmware is stored in read-only, persistent memory. This non-volatile memory does not self-delete and in many cases is not updated. Firmware has become vulnerable to different attacks like rootkits and even steganography. The hard drive has firmware that can be manipulated by malicious actors. Extracting this data is difficult and requires specialized training and expensive tools.
A snapshot can be a useful tool in capturing the exact state of running systems. Snapshots capture volatile data in an ever-changing environment. This tool is not a substitute for the sector-by-sector copy of a disk. The snapshots can be saved for future examination. Snapshots are valuable only if taken of a running system that is currently experiencing an attack.
A cache is stored data that is used to improve the speed of the computing process. There are different caches in a computer system. Address resolution protocol, or ARP, matches IP with MAC addresses. This protocol has a built-in caching component that saves CPU time and network bandwidth by referring to the cache. Internet browser history is also cached and can provide valuable evidence regarding search history.
Network forensic data plays an important role in an investigation. Network appliances that are important in an investigation are firewall, router, switches, domain controllers, DHCP servers, application servers and web proxy servers. There are also applications on the network including intrusion detection and intrusion protection systems.
In computer forensics an artifact is an object that contains forensic value. Forensic value is evidence found on hardware or in areas like registry hives that show indicators of compromise. These indicators are a digital sign of a breach. It is important to preserve these artifacts and understand their value to a forensic investigation.
That's it for this lesson. In this lesson, we learned the procedure used to prioritize evidence gathering called the order of volatility. We discussed different areas within a network that contain potential evidence such as cache, network appliance, OS, disks and RAM. We also covered artifacts and how they are defined and identified.

9.3.3 Forensic Tools (Lesson Video)

Transcript:

In this lesson, we're going to discuss some of the forensic tools on the market. Some of the tools are Linux-specific, and other others are Windows-centric.

Investigating and gathering evidence for court action is part of handling computer security. These computer forensic investigations require specialized tools to gather evidence without making changes to the devices or their stored data. These tools include imaging software, data extraction tools, and advanced search capabilities.
Let's take a look at three of these tools and how they work. We're going to talk about dd-CLI, Memdump, and WinHex.
The first tool, dd, is an extraction tool. It's one of the oldest forensic tools still in use. It's used in Linux and Unix systems to create bit-by-bit copies of a physical hard drive without mounting the drive beforehand. It uses the dd-CLI command, and it's easy to employ. A raw image is created for forensic analysis, and the user has multiple file extension choices.
Memdump is another data gathering tool. It aggregates the data in the volatile RAM memory from devices. Normally, a second tool is needed to search through all the data in a memdump file.
WinHex is a powerful disk and universal hexadecimal editor. It's used in digital forensics for data recovery. WinHex is Windows-compatible and can be used with a whole bunch of options, making it a very versatile forensic tool.
Now let's move on to imaging tools. Imaging tools must create exact copies of data without making a single changeâ€”not even one bit. FTK Imager is a powerful tool that allows the investigator to acquire, preview, and copy data thoroughly and forensically. Autopsy is exactly what it sounds likeâ€”a forensic tool that investigators use to thoroughly examine extracted data, pictures, and empty disk space in order to determine exactly what happened.
And that's it for this lesson. We talked about Forensics tools and how they fall within a few categories; data gathering, imaging, and extraction. We discussed what forensic tools must be able to do--create an exact image of a disk with perfect integrity and then search large amounts of data for specific file extensions, hidden files, deleted data, and root cause analysis.

9.3.4 Create a Forensic Drive Image with FTK (Demo Video)

Transcript:

In this demonstration, we're going to discuss creating a forensic disk image with the Forensic Toolkit. It's better known as the FTK Imager. In our scenario, we need to examine a hard drive from a malicious employee's workstation. Before you try this for real, make sure that your organization considers you qualified to do this and that you have the backing of your legal department.

The first thing we need to do is create an image of the employee's hard drive. Like I said, we're going to use the FTK Imager to do this. Remember, when we're conducting a forensic investigation, we don't want to modify the evidence in any way, shape, or form. If this situation were to be litigated for some reasonâ€""say, the employee gets fired and then sues the company--then the prosecutor could say that when we conducted our forensic investigation, we planted the evidence on the hard drive. That's why it's crucial to make sure that that hard drive isn't changed in any way during the forensics investigation.
We're going to create an image of that hard drive, and we're going to do all of our testing, examining, and investigative work on the imaged copy of the hard drive, not on the actual hard drive. Once we've created that image, we'll use a second tool to analyze the contents of the hard drive to see if we can find anything that's questionable.
The first thing we need to do is get an image of the hard drive. To do this, we have to connect the hard drive to this forensic workstation. That's problematic because as soon as you connect a hard drive to a Windows workstation, Windows immediately starts writing little bits of data to the driveâ€""but we don't want to modify the drive in any way. So we can't just directly connect the drive to a SATA connector on this workstation. Instead, we need to implement a write blocker, also known as a forensic disk controller. Its job is to block writing to the hard drive. It allows us to connect the employee's hard drive to the write blocker, and then we connect the write blocker to our machine, usually with a USB cable. This prevents any write operations coming from the operating system on the forensic computer from going through to the device that we're analyzing. So remember, when you're conducting a forensic investigation on a hard drive and you're going create an image, always use a write blocker to prevent any type of write operation from occurring on that drive. I've already set this system up with a write blocker, and it's ready to go.
Let's go ahead and use the FTK Imager to create an image that we can analyze. By the way, FTK Imager is a free tool. A lot of the forensic software is very, very expensive, but you don't have to spend a lot of money to be able to conduct a good forensic investigation. There are a lot of free, open source, and legitimate tools for forensic investigations.
Within Access Manager, let's click on Add Evidence Item. Then we have to specify what we're going to add. We're adding a physical drive because I've connected it to a write blocker on this particular system. Click Next.
We have to specify which drive we want to create the image from. You'll notice, when I click the dropdown list, it picked all of the hard drives on this system. You need to be very careful that you don't choose the wrong one. For example, if I were to choose Physical Drive 0, that's my local workstation hard disk drive. We'd be creating an image of my local system, not the actual drive that's being used for evidence. Physical Drive 1 is the drive that I've connected to the write blocker. That's what we want to choose. I'll click Finish. We'll come over here, to the Physical Drive 1, and we'll right-click on it. We want to Export Disk Image.
Under Image Destination, we'll click Add. Then we can specify which type of destination image we want to create. Raw (dd) is the default selection because it's probably one of the most widely used imaging format for forensics, so we'll just leave it set the way it is. Click Next.
We need to document the evidence. Remember, whenever you're conducting a forensic investigation, you need to document everything. In fact, you should take a picture of the entire setup that you're using to analyze this hard disk drive. You should take a picture of the drive, take a picture of how it's connected to the write blocker, and take another picture of how the write blocker is connected to the computer. You might even want to take a video of the entire process.
Under Evidence Item Information, you'll want to assign a case number. Let's do â€"Ëœ1 2 3 4' and evidence number â€"Ëœ5 6 7 8'. Then we'll give it a unique description. We'll enter â€"ËœHD from Mary Worley.' I'll put â€"ËœDana Fellows' down as the examiner. Click Next.
We have to specify where we want to store the image file on my computer. I have a folder for my forensic images. Let's create a new folder, â€"Ëœ1 2 3 4 Mary Worley'. I'll put in the same thing here for Image Filename, â€"Ëœ1 2 3 4 Mary Worley'. If we want to, we can fragment the image--that is, break the image file into multiple pieces. This is a small hard drive. I'm going to set that to zero, which basically means we'll have one image file for the entire hard disk. Click Finish.
We want to make sure that Verify the images after they are created is checked. It's also a good idea to create a directory listing of all the files and the image after they're created, so check that box too. It can be useful for when you're searching for information. Click Start. At this point, the imaging process has started. It'll take a little bit of time to complete, especially if you're going to be working with a big hard disk drive. I'm going to pause the recording now and come back when it's done.
Okay. As you can see, it's almost done verifying the image. In just a few seconds, the process will be complete.

Notice that it's created two different hashes, an MD5 Hash and a SHA1 Hash. For both of these, the hashes match. The MD5 Hash matched, and the SHA1 Hash matched as well. That's good. That's exactly what we want to see. I'll go ahead and hit Close.
Before we end this demo, let's verify that the image file has been created. I'll open File Explorer and navigate to the folder where we saved the image. Here are the various pieces of information that were pulled from the hard drive to create it. We have the image file itself. There's a CSV document that contains a listing of all the filenames and directory names. Last on the list, we have a document that provides a nice summary of the image creation process. It gives us the case number, our evidence number, the description, the examiner, all the information we filled out earlier, and the information about the hard drive itself from Mary Worley's computer. At this point, our image file is created. The next step of the process is to use another tool, such as Autopsy, to examine the image.
That's all for this demo. We used FTK imager to capture a forensic image of a hard drive. We discussed the importance of using a write blocker to keep data from getting tampered with and the importance of examining a copy of the disk, not the original disk itself. Then we made a copy the image and verified that it was saved to the folder we created.

9.3.5 Create a Forensic Drive Image with Guymager (Demo Video)

Transcript:

There are several ways to capture a disk image as part of a forensic investigation. In this demo, we're going to do this with a program called Guymager. Guymager has a graphical user interface, making it a bit easier to use than a command line tool. We're on the Guymager home page, and you can read more about it there. One thing I want to point out on the website is that Guymager does come on several live CDs and security operating systems. We're going to use Kali Linux for our demo, so let's close the browser and get started.

I want to mention a couple of things before we get started. Normally, you'll want to have a write blocker between the disk you're imaging and the forensic workstation that you're working from. In a virtual environment, such as my test system here, I can't really do that. The write blocker would keep data from being written to the disk we're wanting to image, which is very important.
The other thing I want to point out is that Kali has a live CD version that has a lot of forensic tools that my copy doesn't have. Keep that in mind if you're setting up your own lab and be sure to investigate the right copy of Linux that will work best for you.
I said that Guymager is a GUI tool, but it does need to be run as a Sudo user. There's a shortcut for it under the Application Launcher, so if I go up here, down to Forensics, and then over to Forensic Imaging Tools, I see Guymager. When it launches, it warns me that it needs to be started with root rights in order to perform acquisitions. That's no fun, and but we can get around it. I'll launch it from the terminal. So let's click No, I don't want to continue here.
I'll go up here and launch a terminal window. After it loads, I'll type â€”Ëœsudo guymager' and press Enter. It prompts me for a password to continue as an admin, so I'll type that in here. Just a reminder, when you type passwords in Linux, the cursor doesn't move, and you think that you're not really typing. This is normal; it's a security feature. Your keyboard isn't broken. I press Enter, Guymager is launched, and now I can acquire images.
I'll make this full screen to take advantage of all the space. Right away, I notice I have three disks, or partitions. This first one is my hard drive for my Kali machine. I know that because it's a 20-gig disk, and that's what I used. This second one is what I'm after. I know this is it because it's a 2-gig disk, which I plugged in. To acquire an image, I simply right-click and choose Acquire Image from the menu.
Now we have a few choices for the file format. This one is called Expert Witness Format. When we select it, we have the option to fill out all this additional data that would be needed if this was part of a legal investigation. We're not going to pick that one. We're going to pick the Linux dd raw image. This is the format I'm going to use when it's time to examine the image content. Over here, we can split the file into smaller pieces. I have a smaller drive, so I could uncheck that box, but I'll just leave it as-is.
Now I need to put the images somewhere. I have a temp folder for these images, and I'll navigate to /home/dana/temp and click Choose to select that directory. I need to supply a filename, so I'll just enter â€”ËœImage1'. The program puts in the extension, so we don't have to do that. Below here, I'm going to make sure this box is checked so that we have the hash value of the image Calculate MD5. We're also going to verify the image after acquisition. Click Start to get the process going.

We have a very small drive, so this shouldn't take long. In fact, if you look at the progress, you can see we're moving along very nicely. It looks like it's finished, and the indicator light is green. We're done with this part, so let's verify that it acquired the images and saved. I'll minimize Guymager for now.
Now let's go up to our Application Launcher and open up File Manager. Remember, we saved the image in a temp directory under /home/dana, and here it is. I'll slide the mouse over and double-click on temp to open it and view the contents. I can see three files. It does look like Guymager broke my file into two, since I checked the box to split files over 2 gigs. The third file is a log file. Let's open up that log and take a look.
My log file has some info about Guymager itself--the version, timestamp, and so on. I'll scroll down here a little ways. Now I see some information about disk size and other data. I want to go down a little farther, to here. This is more relevant information about the acquisition of the disk. I have the device name, /dev/sda, and the size, format, and so on. Down here, I can see the MD5 hash calculation.
Finally, here, we can see when the image was captured, how long it took, and the speed. At the very bottom, we can see the three files that were created when we ran the program. At this point, our disk is captured. The next step is to examine the contents with another forensic software tool designed to do so.
That's it for this demo. In this demo, we used Guymager to capture a drive.

9.3.6 Create a Forensic Drive Image with DC3DD (Demo Video)

Transcript:

In this demonstration, we're going to create a forensic drive image. It's very important that you understand you can't use standard file copying utilities to create a forensic drive image. You can't use, say, Windows Explorer or File Explorer. Those utilities copy files that have an entry, a record, in the allocation table of the partition where it resides, so it only copies data that's associated with a file or folder in the file system. When you're conducting a forensic investigation, you need all the data on that hard drive, especially the data that's not associated with a particular file or file in the file system, but is still on the hard disk drive. Basically, we're looking for stuff that's been deletedâ€""stuff that someone may be trying to hide. We need to use a drive imaging utility to do this. There are a variety of utilities that you can use. Some cost a lot of money; some cost practically nothing. We're going to use the latter option in this demonstration today.

In this demo, we'll use dc3dd to obtain a raw image of a hard drive. dc3dd was developed at the Department of Defense's Cyber Crime Center, and it's basically an enhanced version of the open source dd command with added features for computer forensics. One of the main characteristics of dc3dd is that it offers the possibility of hashing on the fly with multiple algorithms (MD5, SHA-1, SHA-256, or SHA-512). You'll want to use a write blocker between your machine and the disk you're obtaining an image from.
Before we start looking at how to create the drive image, you need to understand how Linux storage devices are addressed by the Linux system. It's kind of difficult to understand when you're new to Linux, but all storage devices on Linux systems are addressed using a device file located in the /dev directory. If a process needs to write information to a hard disk drive, it writes it to a specific file in the /dev directory, which then redirects the IO data to the appropriate hardware device, such as a hard disk drive.
What we need to do is figure out what the device name is for the drive that we want to image. There are a variety of command line utilities you can use to do this. One way to find the forensic image is to use fdisk and the sudo fdisk 1 parameter.
I think we have enough information to get started. We could go to a terminal and start dc3dd, but I'm going to go up to the Application Launcher and start it from there. I'll come down to Forensics and then select Forensic Imaging Tools. I see dc3dd, so let's click on it and launch it.
The only reason I wanted to start it this way is so that you can see we have a nice manual here to learn more about how to use it. I'm not actually going to go over any of this in this information right here, but I will when we type some of the commands in a minute. I'm going to type â€"Ëœclear' and get a clean screen to work with.
I like to see what disks I have to work with by typing â€"Ëœsudo fdisk' with the â€"Ëœ-l' parameter. Press Enter. Now put in the sudo password. The first disk we'll look at is this one, /dev/sdb. It's a 20-gig disk, and I know that this is the one with my Kali Linux installed on. But this isn't the disk I want to image.
If I go up a little, I see a second disk, /dev/sda. This one is 2 gigs. This is the one I want to image. Make sure you know which disk you're working with when you do this. I'll come down here and type â€"Ëœclear' to clear the screen.

Now we need to type in the command to create the image, tell it where to find the disk, where to store the copy, which hash to use, and name the log file. I'll go ahead and type that in and then come back in a second and explain the command.
Okay, I have the command typed in. The first part is â€”Ëœsudo dc3dd'. This just tells Linux to run our command as root, or basically like an admin in Windows. The next part, â€”Ëœif=/dev/sda', is my input file. That's what the letters I-F stand for, input file. After that, we need to specify where our image will go. O-F stands for output file, so we've typed in â€”Ëœof=/home/dana/temp/imaged2.img'. That's the path where I'll save my image file, and I named it â€”Ëœimage2.img'. Next, we'll use â€”Ëœhash=sha256' for our hash type. We could use MD5 or one of the others types we listed in the intro of this demo, but this will work fine. The last thing we have is â€”Ëœlog=/home/dana/temp/image2.log'. As you can guess, this is just a log file, which is very important to have along with the disk image. It's going to be located in the same directory as our disk image. We'll look at after we create it.
This all looks really good. I'll press Enter to start the disk imaging. Down here, we can see the copy progress. Keep in mind that this is a very small disk without a lot of data, so it's going quickly. It looks like it's done. Down here, I can see when it completed. Up here is the location of the image file. I'll go up and close out of our terminal. Now let's go look in our temp file, confirm that it copied over, and look at our log file.
Next, we'll go up to Application Launcher and over to File Manager. I'll go over to my temp folder and double-click on it to open it. Here are my two files, my image file and my log file. Let's open that log now. It shows us things like the time the image started, the size, where the file was located, our hash value, the output filename, and the time it completed. Our next step would be to use another forensic tool to examine the image itself.
And that's it for this demo. We used the command line utility dc3dd to capture a forensic image from a disk.

9.3.7 Examine a Forensic Drive Image with Autopsy (Demo Video)

Transcript:

After a computer forensic investigator captures an image of a drive, they need to examine it. Autospy is a popular examination tool. It's digital forensic software that's free, open source, and said to have most of the features that you'd find in commercial digital forensics tools. Some of the features include, hash matching, registry analysis, and web analytics, and the ability to do a keyword search. For our demo, we're going to use Autopsy to analyze a disk that has been previously captured and saved to my hard drive.

Double-click on it to start it. Sometimes it takes a minute or so for it to fully launch. We want to create a new case. Click on that option. We'll give it a case name, â€”Ëœ1 2 3 4 Mary Worley'. Let's specify the directory where we're going to store the information we're about to create. Let's put it in the same directory as our image file. We'll keep all the data together. I'll actually create a folder for it and name it â€”ËœAutopsy'. I'll select the folder we just created and then click Next. Enter in a case number, â€”Ëœ1 2 3 4 Mary Worley'. I'll put the examiner's name in here. I'll hit Finish.
This next part is going to take a minute or two while it creates the case and gathers all the files. I'll pause the demo while this is running.
Okay, that took several minutes, and now I'm presented with the Add Data Source page. We have to specify what we want to analyze. We're going to analyze a disk image or VM file. Click Next. We need to specify what image file we want to look at. It's in a folder called Forensic Images under 1 2 3 4 Mary Worley. There's the image file that we created a minute ago. Hit Open. We need to set our time zone. I'm in Mountain Time, so I'll scroll down until I find that and select it. Click Next.
We have to specify exactly what we want to look for. This tool uses what's called Ingest Modules. An ingest module is basically just a piece of software that looks for a particular type of information in the image file. You can come over here and specify what you want to look for. For example, you could go under Keyword Search and specify what type of information you want that particular module to look for. We want to look for all of this information here, so I'll check all the boxes and click Next. Now let's go ahead and click Finish.
The process of analyzing the image file has started. It can take quite some time to complete, depending on the size of disk and amount of data. In my test environment, I don't have a very large disk or very much data, so it should happen pretty quickly. But I'll go ahead and pause the demo while it runs.
At this point, the image file has been thoroughly examined by the Autopsy tool, and the results are displayed here on the left, organized by the type of data or the view of the data that you want to use. It's very useful. For example, it sorts the data by the file type extension.

Let's click on Images. There are 43 of them. Let's see what we have. If I click this one, WACC classroom.jpg, I can see the image down here, in a preview pane. It looks like a picture of a computer lab or classroom.
See this one up here, with the red X? This is a file that was deleted on the hard drive. Of course, as you probably know, when you delete something, you don't actually delete it at all--you just delete the pointer, or reference to it. The file won't go away until the drive is formatted or overwritten. Even then, files are sometimes recoverable. Down in the preview, this looks like a screen shot of something.
I'll click on Videos. Over in the listing, I have four videos. One's been deleted. When I click on Audio, my list is the same as it was for videos, so Autopsy must recognize that there are audio files as part of the videos. Under Documents, I have some Microsoft Office documents. I could export those out and look at the contents in the supported programs if I wanted to. I have a few PDF documents as well, along with some plain text files. Once again, a few of these have been deleted, as you can see by the red X. I have no executable files to look at, so we'll skip those. Autopsy does give us a list of just the deleted files, all grouped together. That is handy if I was focused just on what Mary may have deleted and might be trying to hide.
I have a few more categories. We have Recycle Bin and something called User Content Suspected. I'll make my way down to the email addresses. Out of concern for confidentiality, I'm not going to open this up because I'm not sure exactly what's on this disk. Just to clarify, when we see things like emails addresses, IP addresses, URLs, and so on, it does not mean email accounts configured on the system, but any email that shows up on the disk in a document, spreadsheet, etc.
Under IP addresses, I see 0.1.2.3. This might be a simple false positive because the format is somewhat like an IP address. Under phone numbers, I have some phony-looking phone numbers. This looks like something from TV, since they have a 555 prefix. I have a bunch of URLs listed. This is handy for seeing where the person has been spending their time on the web.
I have Hashset Hits, but there's nothing there to see. Right under this, I actually have Email Messages, but there aren't any to look at on this disk. I have Credit Cards down here. Once again, I'm not going to click on those and open them because I'm not sure what I might find. And now we're at the bottom of the list.
Now, there are entire courses and degree programs on how to use this product and the whole legal process that goes along with it. This demo is a very brief overview of what the software is capable of doing. We didn't even look at things such as geolocation, timeline, report generation, or other featuresâ€”there's a lot more to learn!
That's it for this demonstration. In this demo, we used Autopsy to examine a disk image.

9.3.8 Forensic Data Integrity and Preservation (Lesson Video)

Transcript:

Data integrity and preservation are fundamental aspects of digital forensics, ensuring the reliability and usefulness of the data. They serve to maintain and protect the original state of digital evidence from the moment of collection to its presentation in court. Any intentional or unintentional alteration can compromise the accuracy of the evidence, thereby undermining the entire forensic investigation. This means that evidence acquisition, imaging, and storage all need to be done using well-defined processes.

Evidence should be captured in the order of volatility, from more volatile to less volatile. The ISOC best practice guide to evidence collection and archiving recommends the following order: First, CPU registers and cache memory—including cache on disk controllers, graphics cards, etc. The contents of nonpersistent system memory, or RAM, including routing table, ARP cache, process table, and kernel statistics. Then, data is stored on persistent mass storage devices like HDDs, SSDs, and flash memory devices, followed by partition and file system blocks, slack space, and free space. Next would be system memory caches, such as swap space, virtual memory, and hibernation files. And finally, user, application, and OS files and directories. Other sources could include remote logging and monitoring data, physical configuration and network topology, and archival media or printed documents.
Data acquisition is complicated by the fact that it's more difficult to capture evidence from a digital crime scene than it is from a physical one. For example, some evidence could be lost if a computer system is powered off; on the other hand, other evidence may be unobtainable until after the system has been powered off. Because of this, it's important to know the three states for persistent storage acquisition.
Live acquisition means copying the data while the host is still running. This may capture more evidence or more data for analysis and reduce the impact on overall services. Still, the data on the actual disks will have changed, so this method

may not produce legally acceptable evidence. It may also alert the threat actor and allow time for them to perform anti-forensics.
With static acquisition, the host is shut down normally. If malware is a concern, this method runs the risk that the malware will detect the shutdown process and perform anti-forensics to try to remove traces of itself.
If this is the case, static acquisition by pulling the plug instead of powering down may be a solution. This means disconnecting the power at the wall socket (not the hardware power-off button). This is most likely to preserve the storage devices in a forensically clean state, but there's the risk of corrupting data.
Once the target disk has been safely attached to the forensics workstation, data acquisition proceeds as follows:
A cryptographic hash of the source disk media is made using either the MD5 or SHA hashing function. A bit-by-bit copy of the source media is made using an imaging utility. A second hash is then made of the image, which should match the original hash of the media. A copy is made of the reference image, validated again by the checksum. All analysis is performed on the copy.
This proof of integrity ensures non-repudiation. If the provenance of the evidence is certain, the threat actor identified by analysis of the evidence can't deny their actions. The hashes prove that no modification has been made to the image.
That's it for this lesson. In this lesson, we discussed data integrity and preservation. We reviewed the order of volatility that requires that evidence be captured in order of volatility from more volatile to less volatile. We also talked about ensuring acquisition integrity by leveraging the different states of persistent storage acquisition: live acquisition, static acquisition, powered down, and static acquisition, unplugged. Lastly, we discussed how proof of evidence integrity helps to ensure non-repudiation.

9.3.9 Forensic Investigation Facts

Digital forensic analysis involves examining evidence gathered from computer systems and networks to uncover relevant information, such as deleted files, timestamps, user activity, and unauthorized traffic. There are many processes and tools for acquiring different kinds of digital evidence from computer hosts and networks. These processes must demonstrate exactly how the evidence was acquired and that it is a true copy of the system state at the time of the event.

This lesson covers the following topics:

- Due process and legal hold
- Chain of custody
- Reporting
- Data sources
- System memory acquisition
- Data image acquisition

Due Process and Legal Hold

Digital forensics is the practice of collecting evidence from computer systems to a standard that will be accepted in a court of law. Forensics investigations are most likely to be launched to prosecute crimes arising from insider threats, notably fraud or misuse of equipment. Prosecuting external threat sources is often difficult, as the threat actor may well be in a different country or have taken effective steps to disguise their location and identity. Such prosecutions are normally initiated by law enforcement agencies, where the threat is directed against military or governmental agencies or is linked to organized crime.

Due process is a term used in US and UK common law to require that people only be convicted of crimes following the fair application of the laws of the land. More generally, due process can be understood to mean having a set of procedural safeguards to ensure fairness. This principle is central to forensic investigation. If a forensic investigation is launched (or if one is a possibility), it is important that technicians and managers are aware of the processes that the investigation will use. It

is vital that they can assist the investigator and that they do not do anything to compromise the investigation. In a trial, defense counsel will try to exploit any uncertainty or mistake regarding the integrity of evidence or the process of collecting it.

Legal hold refers to the fact that information that may be relevant to a court case must be preserved. Information subject to legal hold might be defined by regulators or industry best practice, or there may be a litigation notice from law enforcement or lawyers pursuing a civil action. This means that computer systems may be taken as evidence, with all the obvious disruption to a network that entails. A company subject to legal hold will usually have to suspend any routine deletion/destruction of electronic or paper records and logs.

Chain of Custody

The host devices and media taken from the crime scene should be labeled, bagged, and sealed, using tamper-evident bags. It is also appropriate to ensure that the bags have antistatic shielding to reduce the possibility that data will be damaged or corrupted on the electronic media by electrostatic discharge (ESD). Each piece of evidence should be documented by a chain of custody form. The chain of custody documentation records where, when, and who collected the evidence, who subsequently handled it, and where it was stored. This establishes integrity and proper handling of evidence. When security breaches go to trial, the chain of custody protects an organization against accusations that evidence has either been tampered with or is different than it was when it was collected. Every person in the chain who handles evidence must log the methods and tools they used.

The evidence should be stored in a secure facility; this not only means access control, but also environmental control, so that the electronic systems are not damaged by condensation, ESD, fire, and other hazards.

Reporting

Digital forensics reporting summarizes the significant contents of the digital data and the conclusions from the investigator's analysis. It is important to note that strong ethical principles must guide forensics analysis:

- Analysis must be performed without bias. Conclusions and opinions should be formed only from the direct evidence under analysis.
- Analysis methods must be repeatable by third parties with access to the same evidence.
- Ideally, the evidence must not be changed or manipulated. If a device used as evidence must be manipulated to facilitate analysis (disabling the lock feature of a mobile phone or preventing a remote wipe, for example), the reasons for doing so must be sound and the process of doing so must be recorded.

Defense counsel may try to use any deviation of good ethical and professional behavior to have the forensics investigator's findings dismissed.

A forensic examination of a device that contains electronically stored information (ESI) entails a search of the whole drive, including both allocated and unallocated sectors, for instance. E-discovery is a means of filtering the relevant evidence produced from all the data gathered by a forensic examination and storing it in a database in a format such that it can be used as evidence in a trial. E-discovery software tools have been produced to assist this process. Some of the functions of e-discovery suites are as follows:

- Identify and de-duplicate files and metadata —many files on a computer system are "standard" installed files or copies of the same file. E-discovery filters these types of files, reducing the volume of data that must be analyzed.
- Search —allow investigators to locate files of interest to the case. As well as keyword search, software might support semantic search. Semantic search matches keywords if they correspond to a particular context.

Tags —apply standardized keywords or labels to files and metadata to help organize the evidence. Tags might be used to indicate relevancy to the case or part of the case or to show confidentiality, for instance.

Security —at all points, evidence must be shown to have been stored, transmitted, and analyzed without tampering.

Disclosure —an important part of trial procedure is that the same evidence be made available to both plaintiff and defendant. E-discovery can fulfill this requirement. Recent court cases have required parties to a court case to provide searchable ESI rather than paper records.

Data Sources

The following table outlines several data sources for forensic investigations along with their descriptions.

Source	Description
Dashboards	An event dashboard provides a console to work from for day-to-day incident response. It provides a summary of information drawn from the underlying data sources to support some work tasks. Separate dashboards can be created to suit many different purposes. An incident handler's dashboard will contain uncategorized events that have been assigned to their account, plus visualizations (graphs and tables) showing key status metrics. A manager's dashboard would show overall status indicators, such as number of unclassified events for all event handlers.
Log data	Log data is a critical resource for investigating security incidents. As well as the log format, you must also consider the range of sources for log files, and know how to determine what type of log file will best support any given investigation scenario.
Host operating system logs	An operating system (OS) keeps a variety of logs to record events as users and software interact with the system. Different log files represent different aspects of system functionality. These files are intended to hold events of the same general nature. Some files hold events from different process sources; others are utilized by a single source only.
Linux logs	Linux logging can be implemented differently for each distribution. Some distibutions use syslog to direct messages relating to a particular subsystem to a flat text file. Other distributions use Journald as a unified logging system with a binary, rather than plaintext, file format. Journald messages are read using the journalctl command, but it can be configured to export some messages to text files via syslog.
Windows logs	The three main Windows event log files are the following: Application—events generated by application processes, such as when there is a crash, or when an app is installed or removed. Security—audit events, such as a failed login or access to a file being denied. System—events generated by the operating system's kernel processes and services, such as when a service or driver cannot start, when a service's startup type is changed, or when the computer shuts down.
Application logs	An application log file is simply one that is managed by an application rather than the OS. The application may use Event Viewer or syslog to write event data using a standard format, or it might write log files to its own application directories in whatever format the developer has selected.

Source	Description
	In Windows Event Viewer, there is a specific application log, which can be written to by any authenticated account. There are also separate custom application and service logs, which are managed by specific processes. The app developer chooses which log to use, or whether to implement a logging system without using Event Viewer. Check the product documentation to find out where events for a particular software app are logged.
Endpoint logs	An endpoint log is likely to refer to events monitored by security software running on the host, rather than by the OS itself. This can include host-based firewalls and intrusion detection, vulnerability scanners, and antivirus/antimalware protection suites. Suites that integrate these functions into a single product are often referred to as an endpoint protection platform (EPP), enhanced detection and response (EDR), or extended detection and response (XDR). These security tools can be directly integrated with a SIEM using agent-based software.
Network logs	Network logs are generated by appliances such as routers, firewalls, switches, and access points. Log files will record the operation and status of the appliance itself—the system log for the appliance—plus traffic and access logs recording network behavior.
IPS/IDS logs	An IPS/IDS log is an event when a traffic pattern is matched to a rule. As this can generate a very high volume of events, it might be appropriate to only log high sensitivity/impact rules. As with firewall logging, a single packet might trigger multiple rules.
File	File metadata is stored as attributes. The file system tracks when a file was created, accessed, and modified. A file might be assigned a security attribute, such as marking it as read-only or as a hidden or system file. The ACL attached to a file showing its permissions represents another type of attribute. Finally, the file may have extended attributes recording an author, copyright information, or tags for indexing/searching.
Web	When a client requests a resource from a web server, the server returns the resource plus headers setting or describing its properties. Also, the client can include headers in its request. One key use of headers is to transmit authorization information, in the form of cookies. Headers describing the type of data returned (text or binary, for instance) can also be of interest. The contents of headers can be inspected using the standard tools built into web browsers. Header information may also be logged by a web server.
Email	An email's Internet header contains address information for the recipient and sender, plus details of the servers handling transmission of the message between them. When an email is created, the mail user agent (MUA) creates an initial header and forwards the message to a mail delivery agent (MDA). The MDA should perform checks that the sender is authorized to issue messages from the domain. Assuming the email isn't being delivered locally at the same domain, the MDA adds or amends its own header and then transmits the message to a message transfer agent (MTA). The MTA routes the message to the recipient, with the message passing via one or more additional MTAs, such as SMTP servers operated by ISPs or mail security gateways. Each MTA adds information to the header. Headers aren't exposed to the user by most email applications. You can view and copy headers from a mail client via a message properties/options/source command. MTAs can add a lot of information in each received header, such as the results of spam checking. If you use a plaintext editor to view the header, it can be difficult to identify where each part begins and ends. Fortunately, there are plenty of tools available to parse headers and display them in a more structured format. One example is the Message Analyzer tool, available as part of the Microsoft Remote Connectivity Analyzer (testconnectivity.microsoft.com/tests/o365). This will lay out the hops that the message took more clearly and break out the headers added by each MTA.

System Memory Acquisition

System memory is volatile data held in Random Access Memory (RAM) modules. Volatile means that the data is lost when power is removed. A system memory dump creates an image file that can be analyzed to identify the processes that are running, the contents of temporary file systems, registry data, network connections, cryptographic keys, and more. It can also be a means of accessing data that is encrypted when stored on a mass storage device.

A specialist hardware or software tool can capture the contents of memory while the host is running. Unfortunately, this type of tool needs to be preinstalled as it requires a kernel mode driver to dump any data of interest. Various commercial tools are available to perform system memory acquisition on Windows.

Data Image Acquisition

Disk image acquisition refers to acquiring data from nonvolatile storage. Nonvolatile storage includes hard disk drives (HDDs), solid state drives (SSDs), firmware, other types of flash memory (USB thumb drives and memory cards), and optical media (CD, DVD, and Blu-ray). This can also be referred to as device acquisition, meaning the SSD storage in a smartphone or media player. Disk acquisition will also capture the OS installation if the boot volume is included.

Given sufficient time at the scene, an investigator might decide to perform both a live and static acquisition. Whichever method is used, it is imperative to document the steps taken and supply a timeline and video-recorded evidence of actions taken to acquire the evidence.

It is vital that the evidence collected at the crime scene conforms to a valid timeline. Digital information is susceptible to tampering, so access to the evidence must be tightly controlled. Video recording the whole process of evidence acquisition establishes the provenance of the evidence as deriving directly from the crime scene.

To obtain a forensically sound image from nonvolatile storage, the capture tool must not alter data or metadata (properties) on the source disk or file system. Data acquisition would normally proceed by attaching the target device to a forensics workstation or field capture device equipped with a write blocker. A write blocker prevents any data on the disk or volume from being changed by filtering write commands at the driver and OS level.

9.3.10 Practice Questions (Section Quiz)

q_for_invest_chain_01_secp8

What is the MOST important element related to evidence in addition to the evidence itself?

Answers:

Photographs of the crime scene

***Chain of custody document**

Witness testimony

Completeness

Explanation:

The chain of custody document is the most important item related to the evidence.

Nothing is more important than the chain of custody document, including photographs.

Witness testimony can be helpful, but it is not more important than the chain of custody document.

Completeness of the evidence is beneficial, but it is not as beneficial as a reliable chain of custody document.

q_for_invest_chain_02_secp8

What is the purpose of a chain of custody?

Answers:

Retaining evidence integrity.

Detailing the timeline between creation and discovery of evidence.

Identifying the owner of the evidence.

***Arriving at conclusions from the investigator's analysis.**

Explanation:

The chain of custody is used to track the people who came in contact with the evidence. The chain of custody starts at the moment evidence is discovered and lists the identity of the person who discovered, logged, gathered, protected, transported, stored, and presented the evidence. The chain of custody helps to ensure the admissibility of evidence in court.

Legal hold refers to the fact that information that may be relevant to a court case must be preserved. This includes retaining (preserving) the integrity of evidence.

Given sufficient time at the scene, an investigator might decide to perform both a live and static acquisition. As part of this process, the investigator normally details the timeline between the creation and discovery of evidence.

Digital forensics reporting summarizes the significant contents of the digital data and the conclusions from the investigator's analysis.

q_for_invest_chain_03_secp8

You have been asked to draft a document related to evidence-gathering that contains details about personnel in possession and control of evidence from the time of discovery up through the time of presentation in court.

Which type of document is this?

Answers:

CPS (certificate practice statement)

FIPS-140

Rules of evidence

***Chain of custody**

Explanation:

The chain of custody is a document related to evidence-gathering that contains details about personnel in possession and control of evidence from the time of discovery up through the time of presentation in court.

A CPS (certificate practice statement) is a document written by a certificate authority outlining their certificate handling, management, and administration procedures.

FIPS-140 is a government standard that defines procedures, hardware, and software that can be employed when performing forensic investigations of cybercrime.

The rules of evidence are the restrictions that must be adhered to in order to ensure the admissibility of collected evidence.

q_for_invest_dashboards_secp8

A CEO asks the tech department to create a console that shows day-to-day incident response and summaries of information drawn from underlying data sources.

What can the tech department present to the CEO as a viable option?

Answers:

***Dashboards**

Network logs

Metadata

Log data

Explanation:

An event dashboard provides a console to work from for day-to-day incident response and a summary of information drawn from the underlying data sources to support some work tasks.

Generated by appliances such as routers, firewalls, switches, and access points, network logs will record the operation and status of the appliance itself, the system logs for the appliance, plus traffic and access logs recording network behavior.

Metadata is the properties of data created by an application, stored on media, or transmitted over a network.

Log data is a critical resource for investigating security incidents. Although kept and analyzed on each host individually, most organizations require better visibility into data sources and host monitoring.

q_for_invest_data_image_secp8

You are a digital forensic analyst and you need to acquire a data image from a computer system as part of an ongoing investigation.

Which of the following steps should you take to ensure the integrity of the evidence and the investigation?

Answers:

Turn off the computer system immediately to prevent any further changes to the data.

***Use a write-blocking device when creating the data image to prevent any changes to the original data.**

Make changes to the system settings to facilitate the data image acquisition process.

Keep documenting the process of data image acquisition, including the tools and methods used, as a low priority.

Explanation:

Using a write-blocking device when creating the data image ensures that the original data cannot be altered during the acquisition process is the correct answer. This is a crucial step in preserving the integrity of the evidence.

Turning off the computer system immediately could result in loss of volatile data and could potentially alter the state of the system, which could compromise the integrity of the evidence.

Making changes to the system settings could alter the state of the system and the data, which could compromise the integrity of the evidence. Any changes to the system should be avoided during the data image acquisition process.

Documenting the process of data image acquisition is a high priority, including the tools and methods used, is a crucial part of the investigation. This documentation can serve as a record of the steps taken during the investigation and can be used to verify the integrity of the evidence and the investigation process.

q_for_invest_data_sources_secp8

You are a digital forensic analyst working on a high-profile case.

You have been given access to a variety of data sources, including dashboards, log data, and host operating system logs. You need to determine the most effective way to gather evidence for your investigation.

Which of the following approaches would be the MOST effective?

Answers:

Rely solely on the dashboard as it provides a summary of information drawn from the underlying data sources.

Focus only on the log data, as it is a critical resource for investigating security incidents.

Concentrate on the host operating system logs as they record events as users and software interact with the system.

***Utilize all the data sources (dashboards, log data, and host operating system logs) to gather a comprehensive set of evidence.**

Explanation:

The most effective approach would be to utilize all the data sources, such as dashboards, log data, and host operating system logs. Each of these sources provides a different type of information and can contribute to a comprehensive understanding of the events that occurred. By using all available data sources, a digital forensic analyst can gather the most complete set of evidence for their investigation.

Relying solely on the dashboard would not be the most effective approach. While dashboards provide a summary of information, they may not contain all the detailed data needed for a thorough investigation. They are best used for day-to-day incident response and to provide an overview of the situation.

Focusing only on the log data would also not be the most effective approach. While log data is indeed a critical resource for investigating security incidents, it is just one piece of the puzzle. It provides valuable information about events that have occurred, but it may not provide the full context needed for a comprehensive investigation.

Concentrating only on the host operating system logs would not be the most effective approach either. These logs do record events as users and software interact with the system, but they represent just one aspect of system functionality. They may not provide a complete picture of the events that occurred.

q_for_invest_due_process_secp8

In cybersecurity investigations, why is it crucial to ensure the admissibility of digital evidence collected from computer systems?

Answers:

Digital evidence is often visible to the naked eye, ensuring its authenticity.

***Due process and the fair application of laws require proper handling of digital evidence.**

The location and identity of threat actors are easily identifiable through digital evidence.

Threat actors can tamper with digital evidence without affecting its integrity.

Explanation:

Due process demands that incident response teams handle evidence collected in cybersecurity investigations meticulously and fairly. Due process ensures that individuals are only convicted of crimes based on unbiased and admissible evidence, contributing to the integrity of the legal system.

Digital evidence, like DNA or fingerprints, is latent, meaning the naked eye cannot see it, and it requires proper interpretation using specialized processes or machines.

Digital forensics helps reveal the location and identity of threat actors through a systematic investigative approach, even if they have hidden their information.

Preserving digital evidence without changes is crucial for maintaining its authenticity and reliability. Proper documentation and forensic procedures are necessary for admissibility in court and trustworthy investigations.

q_for_invest_e-discovery_secp8

A lawyer is preparing a subpoena for an upcoming cybercrime case and is consulting with a digital forensics specialist.

The lawyer explains the need for the ability to parse through data quickly and provide a copy of everything found to the opposing counsel.

Which utility can accomplish these requests?

Answers:

***E-discovery**

Legal hold

Due process

Live acquisition

Explanation:

E-discovery is the means of gathering digital information for a court case. Several e-discovery utilities provide searches based on syntax, keywords, and file type. The lawyer could easily share this type of electronically stored information with opposing counsel.

Legal hold refers to the maintainance of information potentially relevant to a case. Legal holds include taking papers, hard drives, CDs, workstations, and servers.

Due process is the legal term for a a fair trial that leads to being sentenced for a crime or admonished of it. Procedural safeguards are in effect to ensure fairness throughout the trial.

Live acquisition means copying information while the system is still running. Information gathered via this means is not always admissible.

q_for_invest_evidence_01_secp8

A company's cybersecurity team investigates a potential data breach on its network by examining various data sources to gather evidence.

What is the significance of ensuring the evidence is a true copy of the system state at the time of the breach?

Answers:

It prevents unauthorized user access to the investigation.

It accelerates recovery by restoring the system to the state before the breach.

***It establishes the credibility and integrity of the evidence.**

It eliminates the need for documentation in the investigation.

Explanation:

It is essential to ensure that the evidence accurately represents the system state during the breach to maintain its credibility and integrity. This process helps validate the authenticity of the evidence and aids in a successful investigation.

Although ensuring a true copy of the system state does not primarily prevent unauthorized access to the investigation, it is crucial for maintaining the accuracy and reliability of the evidence.

While restoring the system might be important for recovery, it does not address the importance of accurate evidence for legal proceedings.

Evidence is always accompanied by the proper documentation to help verify the existence and validity of the evidence.

q_for_invest_evidence_02_secp8

While investigating a potential cybercrime, a junior digital forensics specialist leaves an important hard drive in a public area overnight.

A senior digital forensics specialist finds the hard drive in the morning and says that it is no longer evidence in the case.

What made the hard drive unusable in court? (Select two.)

Answers:

***The forensics team did not maintain the chain of custody.**

***The forensics team did not maintain the provenance of the hard drive.**

The forensics team did not maintain the legal hold of the hard drive.

The forensics team did not maintain the order of volatility for the hard drive.

The forensics team did not provide a digital forensics report.

Explanation:

The following aspects of this situation make the hard drive unusable in court:

Maintaining the proper chain of custody on any physical evidence at all times is crucial. The hard drive left overnight in a public location is suspect for compromise, rendering it inadmissible in a court of law.

Provenance shows that evidence moves directly from the crime scene without tampering. Provenance is no longer provable, as the hard drive was left alone overnight.

Legal hold refers to preserving information relevant to a court case. Legal hold includes data or files, both paper and digital. It does not impact the usability of evidence.

The order of volatility is capturing data concerning volatility from most to least volatile. Order of volatility would not make a hard drive inadmissible in court. It does not impact the usability of evidence.

Digital forensics reporting summarizes the significant contents of the digital data and the conclusions from the investigator's analysis. It does not impact the usability of evidence.

q_for_invest_file_metadata_secp8

A forensic analyst at an international law enforcement agency investigates a sophisticated cyber-espionage case.

The analyst must uncover the timeline of document interactions, detect concealed or system-protected files, interpret categories of digital events, and trace digital breadcrumbs left behind during media uploads on social platforms.

What combination of data sources would provide the MOST comprehensive information for this multifaceted investigation?

Answers:

***File metadata with extended attributes and network transaction logs.**

Network transaction logs and gateway security logs.

File metadata and event logs.

Event logs and gateway security logs.

Explanation:

Paired with network transaction logs, file metadata with extended attributes provides a comprehensive understanding of document interactions, including hidden details from online actions and network operations.

Network transaction logs and gateway security logs offer insights into network operations and rule-based activities, but need more depth for understanding file interactions or hidden information in online uploads.

File metadata and event logs provide a detailed view of file creation, access, modifications, and event sources, but have limitations in capturing online media upload traces.

Event logs and gateway security logs mainly focus on event sources and network connections, missing the in-depth view of document-specific details or hidden clues from online interactions.

q_for_invest_legal_hold_01_secp8

Your company is about to begin litigation, and you need to gather information. You need to get emails, memos, invoices, and other electronic documents from employees. You'd also like to get printed, physical copies of documents.

Which tool would you use to gather this information?

Answers:

***Legal hold**

Chain of custody

Timestamps

Timeline of events

Explanation:

You would use a legal hold. The purpose behind a legal hold is to help ease the burden of the IT and legal teams as they gather evidentiary documentation. This notice instructs employees to retain any electronically stored information, or ESI.

The chain of custody proves that no one has tampered with the gathered evidence .

Timestamps provide an exact date and time of an event and must be accurate to be admissible.

A timeline of events is required for digital forensic evidence to be admissible and to prove who is most responsible for what occurred.

q_for_invest_legal_hold_02_secp8

A cybersecurity manager is preparing to begin working when a police officer comes through the door waving a subpoena. The officer states that the company is under investigation for suspicious activities relating to recent overseas sales, and they are taking the servers with them.

What gives police officers the right to take the servers?

Answers:

***Legal hold**

Due process

Digital forensics

Data acquisition

Explanation:

Legal hold refers to the maintenance of information potentially relevant to a case. Legal holds include taking papers, hard drives, CDs, workstations, and servers.

Due process is the legal term for a fair trial before someone is sentenced for a crime or absolved. Procedural safeguards are in effect to ensure fairness throughout the trial.

Digital forensics is the process of obtaining the information required for a court case. It also determines procedures that ensure the information is admissible in a court of law.

Data acquisition is the tools and techniques used to create a forensically sound copy of the data. The data cannot have changes to be admissible.

q_for_invest_memory_dump_secp8

As a digital forensics investigator, you are tasked with investigating a potential data breach in your organization. You suspect that a sophisticated malware has infiltrated the system and is deleting its traces from the hard drive after executing its operations.

Which of the following steps would be the MOST effective in capturing the evidence of this malware's activity?

Answers:

Running a full system antivirus scan.

Checking the system's event logs.

***Performing a system memory dump.**

Conducting a network traffic analysis.

Explanation:

Performing a system memory dump is the correct answer. A system memory dump involves capturing the contents of the system's RAM. Since the suspected malware is running and then deleting its traces, its activities would be present in the system memory. A memory dump would provide a snapshot of the system's state at a particular point in time, including the activities of all running processes, which would provide the necessary evidence.

While running a full system antivirus scan is a standard procedure in investigating potential malware infections, sophisticated malware can often evade antivirus scans. Moreover, if the malware is deleting its traces from the hard drive, the antivirus scan might not find any evidence of its activity.

System logs can provide valuable information about system activities, including potential malware operations. However, advanced malware often has the capability to delete or alter these logs to cover its tracks. Therefore, relying solely on system logs might not provide the necessary evidence.

While network traffic analysis can provide evidence of malware communication with external servers, it might not provide direct evidence of the malware's activity on the system. Furthermore, if the malware is using advanced techniques like encryption or steganography to hide its network communication, the network traffic analysis might not reveal any suspicious activity.

q_for_invest_recording_secp8

When conducting a cybersecurity investigation, how does recording the evidence acquisition process on video help to ensure the collected evidence's integrity?

Answers:

Video recording ensures that no one can tamper with the evidence.

Video recording provides a backup of the collected digital data.

Video recording verifies the authenticity of the forensic workstation.

***Video recording proves the evidence originated directly from the crime scene.**

Explanation:

Video recording of the evidence acquisition process establishes its provenance, demonstrating that law enforcement retrieved it directly from the crime scene. This visual record helps validate the authenticity and integrity of the collected evidence.

While video recording can help establish the integrity of the evidence-collection process, it does not guarantee that someone cannot tamper with the evidence after collection.

Video recording focuses on capturing the evidence acquisition process rather than providing a backup of the collected digital data.

While video recording can provide insights into the activities of the forensic workstation, its primary purpose is to document the evidence acquisition process and its connection to the crime scene.

q_for_invest_reporting_secp8

As a digital forensic analyst, you have completed an investigation and are now tasked with creating a report summarizing your findings.

Which of the following principles should guide your report writing?

Answers:

The report should be biased towards the hypothesis you initially formed about the case.

The analysis methods used should not be repeatable by third parties.

***The evidence must not be changed or manipulated unless necessary. If it is changed or manipulated, the reasons why and process used must be recorded.**

The report should only include conclusions and opinions formed from the direct evidence under analysis.

Explanation:

The evidence in a digital forensics investigation must not be changed or manipulated unless it is necessary for the analysis. If the evidence must be manipulated, the reasons for doing so and the process of doing so must be recorded. Recording this information ensures the integrity of the evidence and the investigation process.

A digital forensics report should not be biased toward any hypothesis. The report should be objective and based on the evidence found during the investigation. Any bias could compromise the integrity of the investigation and the report.

The analysis methods used in a digital forensics investigation should be repeatable by third parties. Repeatable results ensure that the investigation process is transparent and can be verified by others if needed.

The report should only include conclusions and opinions that are formed from the direct evidence under analysis. Following this policy ensures that the report is based on factual information and not on speculation or assumptions.

9.4 Redundancy

As you study this section, answer the following questions:

Why is redundancy important to network security?

Why would an organization use geographic dispersal?

What are the levels of RAID and when would you use each level?

Why would a system administrator want to use load balancers?

What is an uninterrupted power supply used for?

What is the difference between active/active and active/passive?

What is the main advantage of RAID 0? Disadvantage?

What is the difference between RAID 0+1 and RAID 1+0?

Key terms for this section include the following:

Term	Definition
Fault tolerance	The ability to respond to an unexpected hardware or software failure without loss of data or loss of operation.
Redundancy	A method for providing fault tolerance by using duplicate or multiple components that perform the same function.
Geographic dispersion	Using multiple locations to store data to mitigate downtime due to loss of availability at a location.

Multipath	A fault-tolerance technique that gives multiple physical paths between a CPU and a mass-storage appliance.
Load balancers	A process that distributes processing among multiple nodes.
Uninterrupted power supply (UPS)	A stand-alone power supply that allows servers to be gracefully shutdown during a power outage.
Virtual machine (VM)	A computer that uses software components, but acts like a physical machine. A virtual machine resides on a host machine.
Active/active	Two load balancers working in tandem to distribute network traffic.
Active/passive	Two load balancers with one actively working and the second in listening mode to take over if the active machine fails.
Virtual IP	An IP address that can be used by multiple endpoints. It is commonly used in failover systems and for load balancing.
Storage area network (SAN)	A dedicated, high speed network of storage devices. Usually used for file shares.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts Cloud Third-party vendors Network infrastructure High availability Considerations Power 3.2 Given a scenario, apply security principles to secure enterprise infrastructure.

	Infrastructure considerations Device attribute Active vs. passive Load balancer 3.4 Explain the importance of resilience and recovery in security architecture. High availability Load balancing vs. clustering Site considerations Geographic dispersion Power Generators Uninterruptible power supply (UPS) 5.3 Explain the processes associated with third-party risk assessment and management. Vendor selection
TestOut Security Pro	4.1 Protect and Maintain Data files 4.1.2 Implement redundancy

9.4.1 Redundancy (Lesson Video)

Transcript:

Security architecture resilience refers to the design and implementation of systems and networks in a way that allows them to withstand and recover quickly from disruptions or attacks. This includes redundancy, fail-safe mechanisms, and robust incident response plans. By building resilience into the security architecture, cybersecurity teams ensure that even if a breach occurs, the impact is minimized, and normal operations can be restored quickly.

Redundancy strategies are essential to disaster recovery and business continuity planning. These strategies include continuity of operations planning, which involves developing processes and procedures to ensure critical business functions can continue during and after a disruption. Let's look at some of these strategies.
High availability (HA) clustering uses redundant systems that can automatically take over operations in case of failure, minimizing downtime. High availability (HA) is crucial in IT infrastructure, ensuring systems remain operational and accessible with minimal downtime. It involves designing and implementing hardware components, servers, networking, data centers, and physical locations for fault tolerance and redundancy. In a high-availability setup, redundant hardware components, such as power supplies, hard drives, and network interfaces, reduce the risk of failure by allowing the

system to continue functioning if one component fails. Servers are often deployed in clusters or paired configurations, which allows automatic failover from a primary server to a secondary server in case of an issue.
Power redundancy ensures critical infrastructure, such as data centers, has backup power sources to continue operations during an outage. All types of computer systems require a stable power supply to operate. Electrical events, such as voltage spikes or surges, can crash computers and network appliances, while loss of power from under-voltage events or power failures will cause equipment to fail. Power management means deploying systems to ensure that equipment is protected against these events and that network operations remain uninterrupted or recover quickly.
Vendor diversity is essential for several reasons, offering benefits not only in terms of cybersecurity but also in business resilience, innovation, and competition. Relying on a single vendor for all software and hardware solutions can create a single point of failure. The entire infrastructure may be at risk if a vulnerability is discovered in that vendor's products. Vendor diversity mitigates the risk associated with vendor lock-in. It ensures that an organization's operations aren't solely reliant on one vendor's products or services. Diverse vendors bring different perspectives, ideas, and technologies.
Vendor diversity promotes healthy competition in the market, which can lead to better pricing, improved product features, and higher-quality customer support. Different vendors offer unique solutions that cater to specific needs, and having a diverse vendor ecosystem allows organizations to choose the best fit for their requirements. Vendor diversity helps spread the risk associated with
potential product or service failures, security breaches, and other issues. In some industries, regulations or standards may require organizations to maintain vendor diversity to ensure compliance and reduce the risk of supply chain disruptions or security breaches.
Defense-in-depth is a comprehensive cybersecurity strategy that emphasizes the implementation of multiple layers of protection to safeguard an organization's information and infrastructure. This approach is based on the principle that no single security measure can completely protect against all threats. By deploying a variety of defenses at different levels, organizations can create a more resilient security posture that can withstand a wide range of attacks. For example, a defense-in-depth strategy might include perimeter security measures such as firewalls and intrusion detection systems to protect against external threats. Organizations can implement segmentation, secure access controls, and traffic monitoring at the network level to prevent unauthorized access and contain potential breaches. Endpoint security solutions, such as antivirus software and device hardening, help protect individual devices. At the same time, regular patch management ensures that software vulnerabilities are addressed promptly.
Regular testing, including tabletop exercises, failover tests, and simulations, is essential to identify vulnerabilities, evaluate response plans, and improve redundancy measures. By incorporating redundancy strategies, organizations can reduce risks, minimize downtime, and ensure the continuity of their critical business functions.
Testing high availability, load balancing, and failover technologies is critical. It assesses the ability to remain operational during heavy workloads, component failures, or scheduled maintenance. Load testing incorporates specialized software tools to validate a system's performance under expected or peak loads and identify bottlenecks or scalability issues. Failover testing focuses on validating failover processes to ensure a seamless transition between primary and secondary infrastructure. Testing monitoring systems validate effective detection and response to failures and performance issues. Robust testing practices allow organizations to ensure that high availability, load balancing, and failover technologies effectively fulfill their purpose to minimize unexpected outages and maximize performance.
That's it for this lesson. In this lesson, we discussed various redundancy strategies, including high availability, power redundancy, vendor diversity, and defense in depth. We reviewed the importance of testing high availability, load balancing, and failover technologies.

9.4.2 Redundancy Facts

This lesson covers the following topics:

- Implement secure network designs
- Manage redundant power options

Implement Secure Network Designs

The following table describes secure network designs.

Secure Network Designs	Description
Load balancing	A process that distributes processing among multiple nodes.
Active/active	Two load balancers working in tandem to distribute network traffic.
Active/passive	Two load balancers with one actively working and the second in listening mode to take over if the first one becomes unavailable.
Power scheduling	Power scheduling is used to configure an active redundancy. This sends power to networks when a power facility goes down. Power scheduling prevents total loss of power during catastrophic events.
Virtual IP (VIP)	An IP address that is not assigned to an endpoint. VIP is used for load balancing. It typically uses NAT IP address assignment.
Geographic dispersal	The use of multiple locations to store data to mitigate downtime due to location.
Multipath	A fault-tolerance technique that gives multiple physical paths between a CPU and a mass-storage appliance.

Manage Redundant Power Options

Redundant power options are vital. A network without power is useless. Common power options found in datacenters include:

Uninterrupted power supply (UPS). A UPS is a stand-alone bank of batteries that allows for the graceful shutdown of network appliances when power goes out.

Generator. A generator is a large scale device that provides power for an extended period of time. Normally between 24 and 48 hours.

Dual supply. A dual power supply is common in network appliances like servers and firewalls. It allows for one failure and hot-swapping.

Managed power distribution unit (PDU). A managed power distribution unit is a rack-mounted unit that distributes power on a large scale such as a data center.

9.4.3 Hardware Clustering (Lesson Video)

Transcript:

I'll spend a few minutes talking about clustering. Clustering can be an effective way to implement a disaster-recovery plan as well as a way to improve your productivity. A cluster is a group of interconnected servers, also known as nodes, that appear to be a single system to the operating environment. Although clustering can be done on virtual machines, I'll focus this lesson on the unique characteristics of clustering on physical computers.

Hardware clustering provides several benefits. For example, when you use clustering, the throughput and response time are dramatically improved. Since the cluster's nodes appear to be one system, if one node fails, the others in the cluster still provide the services you need and redistribute the workload among the remaining servers. To provide additional performance, more nodes can be added. Theoretically, there's no limit to the number of nodes you can have in your cluster. But you must have software that supports clustering. This software could be built into the operating system itself, such as with Windows Server 2019. In other cases, you may have to purchase a program to help you set up and manage your clusters.

With that introduction, I'll show you how clustering works.

In a typical clustering implementation, there are at least two nodes. They can be connected in multiple ways in order to act seamlessly with each other. First, since the nodes provide services to the workstations that reside on the production network, the clustered nodes are directly connected to the production network. For example, a user at this workstation can access the services on the clustered nodes through the production network.

To increase performance, clustered nodes often have a second network card, allowing them to also be connected to each other through a dedicated network. As you can see here, this network is isolated from the production network. This means that the clustered nodes connected to this dedicated network don't have to compete for bandwidth with the production traffic. When you work with high-availability clusters, this network is also referred to as a heartbeat network. I'll talk more about that in a bit. But, keep in mind that although this is the ideal setup, you don't have to use this second dedicated network. Instead, you could choose to do your clustering over the production network.

Depending on the cluster type you choose and the cluster's purpose, the nodes in your cluster could also share a common storage that's accessible through a storage area network, or SAN. When used, a SAN is often connected to the cluster using fiber-channel connections, which are fiber optic. These connections allow the devices to communicate very quickly with the shared storage. In this setup, the shared storage appears to the operating system as if it were storage installed within the server itself. But in reality, both servers share the same disk storage. This has important implications. It means that whenever Server A writes information to the SAN, it's immediately available to Server B and vice versa.

When planning your cluster, keep in mind that there are a few different types of clusters you can implement.

One commonly used cluster is called a high-availability cluster, or HA cluster. This type of cluster is also known as a failover cluster. The idea behind this specific cluster type is to eliminate downtime when a computer system in the cluster fails. Although the most common size of an HA cluster is two nodes, an HA cluster can have many more.

A high-availability cluster typically uses what's known as an active/passive configuration. With this type of configuration, the active server, or primary server, provides the services to the production network while the passive server, or standby server, waits in the background. If the primary server fails, the passive server becomes the new active server and provides the services to the production network. In this type of configuration, the passive node must be a fully redundant instance of the active node and use the same shared storage. This way, any node in the cluster has access to the same data.

To monitor when the passive server should take over, HA clusters make sure that the other servers in the cluster are alive by sending what are called heartbeats over a dedicated heartbeat network. For example, Server A, our primary server, continually lets Server B know that it's up and running by sending these heartbeats. If Server A fails, Server B no longer hears a heartbeat coming from Server A and assumes that Server A has gone down. It immediately takes over and becomes the new active server. This is possible because both servers use the same shared storage.

Depending on how close together your heartbeat intervals are set, it may take only a few seconds for a passive server to start providing the services that the active server was providing. As such, the user usually notices little to no downtime. But, keep in mind that whatever was in RAM on the failed server is lost. If the server that failed is fixed and brought back online, it becomes the passive server and listens for heartbeats from the current active server.

Another type of cluster you can use is called a load-balancing cluster, which works differently from a high-availability cluster. In a load-balancing cluster, all nodes are always active participants. This is known as an active/active configuration. In this type of cluster, all computers share in the processing workload. In a way, you can think of a load-balancing cluster as a type of supercomputer system. In other words, the processing tasks are distributed among all the nodes within the cluster. Companies that provide web server access to a large clientele typically implement load-balancing clusters to assign the many different queries to different nodes. This optimizes the responses to these requests.

Let's look at an example.

First, notice that instead of using a SAN to provide a common disk storage, each computer has its own disk storage. This isn't a requirement of a load-balancing cluster, but since a SAN can be expensive, some companies might not choose to use them. Still, using a SAN is probably the fastest and most effective way to implement a cluster when feasible.

In some cases, load-balancing clusters might also have a separate device known as a load balancer, which is used to determine which cluster node gets the current request. Load balancing uses an algorithm to determine which server in the cluster should service the request.

Similar to the example, some implementations use a round-robin approach where Server A gets the first request, Server B gets the second, and Server A gets the third.
The systems in a load-balancing cluster can be loosely linked or tightly linked. The tighter the link, the more they act as one computer system. In a loosely linked cluster, each system operates autonomously, but also in conjunction with the other systems at the same time. In a tightly linked system, the systems function as one system called a supercomputing cluster. These systems pool their CPU and storage resources, and they might even pool their memory together so that various processing tasks are distributed between the cluster members.
A key thing to remember when you implement clustering is that the more tightly integrated the systems, the more identical the hardware needs to be.
If you're using a loosely linked cluster, you can use hardware that's slightly more disparate. For example, you can use servers from different manufacturers. But, to implement a tightly linked cluster, the systems need to be identical. So, they should be from the same manufacturer, the same make and model, same processor, same amount of storage, same amount of RAM, and so on.
I don't have time to go into specific clustering implementations on various operating systems. Just be aware that most of your commonly used network operating systems do have some type of clustering solution available, whether it's built into the product itself or whether it's available from a third party.
That's it for this lesson. In this lesson, we gave you an overview of how clustering works. We talked about the role of a cluster and several clustering implementations. Then we looked at high-availability and load-balancing cluster types, and we talked about how you create a supercomputing cluster, or tightly linked cluster, from a load-balancing cluster.

9.4.4 Clustering Facts

This lesson covers the following topics:

- Virtual IP
- Application clustering

Where load balancing distributes traffic between independent processing nodes, clustering allows multiple redundant processing nodes that share data with one another to accept connections. This provides redundancy. If one of the nodes in the cluster stops working, connections can fail over to a working node. To clients, the cluster appears to be a single server. A load balancer distributes client requests across available server nodes in a farm or pool. It is generally associated with managing web traffic, whereas clusters provide redundancy and high availability for systems such as databases, file servers, etc.

Virtual IP

For example, an organization might want to provision two load balancer appliances so the other can handle client connections if one fails. Unlike load balancing with a single appliance, the public IP used to access the service is shared between the two instances in the cluster. This arrangement is called a virtual IP or shared or floating address. The instances are configured with a private connection, on which each is identified by its "real" IP address. This connection runs a redundancy protocol, such as Common Address Redundancy Protocol (CARP), enabling the active node to "own" the virtual IP and respond to connections. The redundancy protocol also implements a heartbeat mechanism to allow failover to the passive node if the active one should suffer a fault.

- With active/passive clustering, if one node is active, the other is passive. The most significant advantage of active/passive configurations is that performance is not adversely affected during failover. However, there are higher hardware and operating system costs because of the unused capacity.
- An active/active cluster means that both nodes are processing connections concurrently. This allows the administrator to use the maximum capacity from the available hardware while all nodes are functional. In the event of a failover, the workload of the failed node is immediately and transparently shifted onto the remaining node. At this time, the workload on the remaining nodes is higher, and performance is degraded.

Application Clustering

Clustering is also very commonly used to provision fault-tolerant application services. If an application server suffers a fault in the middle of a session, the session state data will be lost. Application clustering allows servers in the cluster to communicate session information to one another. For example, if a user logs in on one instance, the next session can start on another, and the new server can access the cookies or other information used to establish the login.

9.4.5 Incorporate Redundancy Strategies

9.4.6 Practice Questions (Section Quiz)

q_redundancy_dual_power_secp8

To prevent server downtime, which of the following components should be installed in a server system redundantly?

Answers:

***Uninterrupted power supply**

CD or DVD drive

RAM modules

Floppy disk drive

Explanation:

To prevent server downtime, you should install uninterrupted power supplies in a server system. If one fails, the other can immediately take over, allowing the server to remain running.

Because it isn't a critical component, a redundant CD or DVD drive probably isn't necessary. Unless data was shared from a disc in the drive, a failed CD or DVD drive probably won't affect the server's functionality.

With most motherboards, there's no way to install redundant RAM modules.

Like CD or DVD drives, the floppy disk drive isn't a critical component. A failed floppy disk drive won't bring the server down.

q_redundancy_hot_swap_secp8

You have been asked to deploy a network solution that includes an alternate location where operational recovery is provided within minutes of a disaster.

Which of the following strategies would you choose?

Answers:

Hot spare

***Hot swapping**

Cold site

Warm site

Explanation:

Hot swapping is a complete disaster recovery facility that could be fully operational within hours or minutes in the event of a disaster. This includes maintaining redundant hardware and up-to-date network data.

A warm site is a remote network location that maintains a backup of data, but it is not always current. Data may be days or weeks old, depending on backup procedures.

A cold site provides a space and sometimes hardware in an alternate location that can be configured when needed. Returning to an operational state may take days.

A hot spare is a redundant hardware component used as a failover solution.

q_redundancy_load_balance_active_secp8

A growing e-commerce company is considering various strategies to ensure its web servers can handle sudden traffic surges without an impact on site availability.

The company is assessing methods that distribute incoming traffic across multiple servers.

Which strategy should the company implement to dynamically allocate the load based on real-time traffic and server conditions?

Answers:

***Active load balancing**

Passive load balancing

Active server pages

Active Directory

Explanation:

Active load balancing constantly monitors server loads and dynamically distributes client requests across multiple servers based on their real-time conditions and capacities. This process is an effective strategy to manage sudden traffic surges and maintain high availability.

Passive load balancing distributes client requests evenly across servers without considering their current loads.

Active server pages are a server-side scripting technology that creates dynamic web pages. While it can improve the website's functionality, it does not directly impact server load distribution.

Active Directory is a service for managing network domains and resources. While Active Directory is a crucial component in many networks, it doesn't contribute to load balancing or handling traffic surges.

q_redundancy_load_balance_passive_secp8

A growing e-commerce company wants to implement a strategy that evenly distributes incoming traffic across multiple servers without constantly monitoring server loads or making adjustments based on real-time conditions.

Which strategy should this company implement to manage load distribution in this manner?

Answers:

***Passive load balancing**

Active Directory

Active Server Pages

Active load balancing

Explanation:

Passive load balancing distributes client requests evenly across servers without considering their current loads. This method aligns with the company's desire to manage load distribution without constantly monitoring real-time conditions.

Active Directory is a service for managing network domains and resources. While essential in many networks, Active Directory doesn't contribute to load balancing or managing traffic surges.

Active Server Pages is a server-side scripting technology that creates dynamic web pages. Active Server Pages can enhance a website's functionality, but does not directly impact server load distribution.

Active load balancing monitors server loads, dynamically distributing client requests based on real-time conditions. While effective for managing traffic surges, this approach does not align with the company's preference for an even distribution method without real-time adjustments.

q_redundancy_load_balance_secp8

A systems engineer is designing a new IT infrastructure for a company that provides a highly used online service. The company wants to ensure that its service communications are efficient and available around the clock.

Which feature should the engineer primarily consider during the design process?

Answers:

***Load balancing**

Multipath

Generators

Replication

Explanation:

Load balancing helps to distribute network or application traffic across several servers, preventing any single server from becoming a bottleneck. This concept is crucial for designing a high-availability system.

Multipath is a fault-tolerance technique that provides multiple physical paths between a CPU and a mass-storage appliance. However, it does not make sure that service communications are efficient and available around the clock.

Generators can be important for maintaining power supply in case of outages, but they do not make sure that service communications are efficient and available around the clock.

Replication is a method of copying data to ensure its availability in case of a hardware failure. However, it does not make sure that service communications are efficient and available around the clock.

q_redundancy_pdu_secp8

A security consultant assesses a company's server room to determine how well it can maintain operations during power interruptions. The consultant evaluates the integration of power distribution units (PDUs) and backup power generators within the security architecture.

Considering the goal of ensuring resilience and recovery in the server room during power interruptions, which primary role does the backup power generator play in conjunction with the PDU?

Answers:

It ensures power load balancing across multiple servers.

It instantly supplies power to PDUs to prevent any momentary lapse during an outage.

***It provides a prolonged source of power to the PDUs after the UPS system depletes its immediate resources.**

It filters and stabilizes the power before it is distributed by the PDU.

Explanation:

A backup power generator supplies prolonged power to PDUs once UPS systems deplete their immediate resources, ensuring continuous operation of servers and essential devices during extended power outages.

While PDUs ensure efficient power load balancing across servers, maintaining consistent energy distribution, backup power generators mainly act as a reserve energy source and are not primarily responsible for balancing.

Though backup power generators serve as a long-term power solution, they do not instantly deliver power in emergencies. Instead, UPS systems serve to provide immediate power responses, bridging the gap until generators activate.

Although it is important to have stable power, backup power generators focus on supplying continuous energy during outages. They do not primarily work to filter or stabilize the power.

q_redundancy_redundancy_secp8

What is the primary security feature that can be designed into a network's infrastructure to protect and support availability?

Answers:

Periodic backups

***Redundancy**

Fiber optic cables

Switches instead of hubs

Explanation:

Redundancy is the primary security feature that can be designed into a network's infrastructure to protect and support availability. This is because it identifies single points of failure.

Periodic backups are better than no backups, but real-time and off-site backups are better protection for availability.

Fiber optic cables are not a real protection for a network's availability, as eavesdropping protection is the only security benefit they provide.

Switches are better than hubs, but there are infrastructure security measures that provide more significant protections for availability.

q_redundancy_ups_01_secp8

A data center manager is evaluating the resilience and recovery capabilities of a company's server room. The manager wants to ensure that in the event of power fluctuations or outages, the company's servers remain operational and maintain data integrity.

The manager focuses on the role of power distribution units (PDUs) and Uninterruptible Power Supplies (UPSs) in this context.

In enhancing the resilience and recovery capabilities of the server room against power interruptions, which primary function does the UPS provide to the servers that directly support this goal?

Answers:

It distributes power to multiple servers simultaneously.

It filters power to remove noise and surges.

***It provides temporary power during an outage, allowing for a graceful shutdown or transition to backup generators.**

It monitors power usage and sends alerts for overconsumption.

Explanation:

A UPS provides temporary power during an outage, ensuring that servers can undergo a graceful shutdown without data loss or continue running until backup generators take over. This function is critical for resilience and recovery as it prevents sudden power loss, leading to data corruption.

While PDUs distribute power to multiple devices, their primary function is not to provide resilience during power interruptions.

Filtering power to remove noise and surges is essential for protecting equipment, but does not directly provide resilience during more prolonged power interruptions.

Monitoring power usage and sending alerts is more about managing power consumption and ensuring efficiency than providing resilience during power outages.

q_redundancy_ups_02_secp8

A corporation is experiencing frequent power failures in its data center, which are causing downtime and resulting in high recovery costs.

Which strategy could the corporation employ to minimize the impact of these power failures?

Answers:

***Implement a UPS system.**

Employ a hybrid cloud strategy.

Implement network segmentation.

Migrate to an SDN.

Explanation:

Uninterruptable power supply (UPS) systems act in the event of a power failure, allowing systems to keep running and/or to be safely shut down, minimizing downtime and associated costs.

Employing a hybrid cloud strategy can be beneficial for many reasons. Although some of the resources are maintainable locally, in a hybrid model, this does not solve the power failures at the data center.

Implementing network segmentation enhances security by separating the network into smaller parts, but does not solve the power failure issues in the data center.

Migrating to a software-defined network (SDN) allows for greater network control and may improve efficiency, but software depends on physical devices, which are experiencing power failures.

q_redundancy_ups_dual_power_secp8

An organization operates a large data center that supports critical business operations. Recently, the organization has struggled with frequent power interruptions leading to downtime and data loss.

To address this issue, the chief information security officer (CISO) decides to review the data center's resilience and recovery strategies, particularly emphasizing backup power.

To increase the resilience and recovery capabilities of the data center and ensure operations continue even during a power failure, which of the following options should the CISO consider? (Select two.)

Answers:

***Implement a UPS.**

***Deploy a dual power supply unit in each server.**

Purchase additional servers.

Enhance the firewall system.

Implement load balancing.

Explanation:

When the input power source fails, an Uninterruptible Power Supply (UPS) provides emergency power to a load. The UPS will ensure the continuous operation of the data center during a power outage, thus enhancing its resilience and recovery capabilities.

A dual power supply unit can ensure an uninterrupted power supply to the servers if one of the power supply units fails, thereby increasing the data center's resilience and recovery capabilities.

While purchasing additional servers may increase the data center's capacity, it does not address the power redundancy issue.

While enhancing the firewall system can help prevent certain types of cyberattacks, it does not contribute directly to resilience, recovery, or power redundancy.

Load balancing is a process that distributes processing among multiple nodes to ensure availability of data and applications. It does not contribute directly to power redundancy.

q_clustering_active_active_sec8

An IT architect of a medium-sized e-commerce business that operates 24/7 is planning to enhance the system's resilience and recovery capabilities.

As part of this project, the architect is considering a clustering solution for the servers. The architect's key objective is high availability and seamless customer experience, even in the event of unexpected server failures.

Which type of clustering setup would BEST meet the needs of this e-commerce business?

Answers:

***Active/Active Clustering.**

Active/Passive Clustering.

No clustering, just a single server.

Active/Passive Clustering with an equal number of active and passive nodes.

Explanation:

Active/Active Clustering is the most suitable for a 24/7 e-commerce business. Both nodes in this setup process the connections concurrently, maximizing the utilization of available resources.

While Active/Passive Clustering provides a degree of resilience, it does not fully utilize the available resources, as one node remains idle unless the active node fails.

A single server and no clustering are not ideal for a 24/7 e-commerce business since a single server does not provide any resilience or recovery options.

This type of setup would involve unnecessary costs for the business as it requires an equal number of passive nodes for each active node.

q_clustering_active_passive_sec8

What is a significant advantage of using an active/passive clustering configuration in a network?

Answers:

Both nodes process connections concurrently, maximizing hardware capacity.

***The performance is not adversely affected during failover.**

The active node can access the cookies or other information used to establish the login.

The public IP used to access the service is shared between the two instances in the cluster.

Explanation:

The performance is not adversely affected during failover is correct. In an active/passive configuration, the performance is not adversely affected during failover because the passive node is ready to take over the workload of the active node immediately if it fails.

In an active/passive configuration, one node is active while the other is passive, meaning they do not process connections concurrently. This is a characteristic of an active/active configuration.

The ability for a node to access cookies or other login information is a feature of application clustering, not specifically active/passive clustering.

The sharing of a public IP between two instances in a cluster is referred to as a virtual IP or shared or floating address, not a characteristic specific to active/passive clustering.

q_clustering_app_clustering_sec8

What is a primary function of application clustering in a network?

Answers:

***It allows servers in the cluster to communicate session information to one another.**

It enables the active node to "own" the virtual IP and respond to connections.

It distributes client requests across available server nodes.

It processes connections concurrently in an active/active cluster.

Explanation:

Application clustering allows servers in the cluster to communicate session information to one another. This means that if a user logs in on one instance, the next session can start on another, and the new server can access the cookies or other information used to establish the login.

The ability for the active node to "own" the virtual IP and respond to connections is a feature of the Common Address Redundancy Protocol (CARP), not a specific feature of application clustering.

The distribution of client requests across available server nodes is a function of a load balancer, not a specific feature of application clustering.

The processing of connections concurrently in an active/active cluster is a characteristic of the cluster configuration, not a specific feature of application clustering.

q_clustering_carp_sec8

What is the primary function of the Common Address Redundancy Protocol (CARP) in a network?

Answers:

To distribute client requests across available server nodes.

***To enable the active node to "own" the virtual IP and respond to connections.**

To communicate session information between servers in a cluster.

To process connections concurrently in an active/active cluster.

Explanation:

CARP enables the active node in a cluster to "own" the virtual IP and respond to connections. It also implements a heartbeat mechanism to allow failover to the passive node if the active one should suffer a fault.

The distribution of client requests across available server nodes is a function of a load balancer, not CARP.

The communication of session information between servers in a cluster is a feature of application clustering, not a function of CARP.

The processing of connections concurrently in an active/active cluster is a characteristic of the cluster configuration, not a function of CARP.

q_clustering_load_balancer_sec8

What is the primary function of a load balancer in a network?

Answers:

***To distribute client requests across available server nodes in a farm or pool.**

To provide a virtual IP or shared or floating address.

To communicate session information between servers in a cluster.

To process connections concurrently in an active/active cluster.

Explanation:

The primary function of a load balancer is to distribute client requests across available server nodes in a farm or pool, managing web traffic and ensuring that no single server becomes overwhelmed.

While a load balancer can be part of a setup that uses a virtual IP or shared or floating address, this is not its primary function. This is more related to the concept of clustering.

The communication of session information between servers in a cluster is a feature of application clustering, not a function of a load balancer.

The processing of connections concurrently in an active/active cluster is a characteristic of the cluster configuration, not a function of a load balancer.

9.5 Backup and Restore

As you study this section, answer the following questions:

- Why are there different backup types?
- How often should you run a full backup?
- How do incremental and differential backups differ?
- How can you implement the 3-2-1 rule?
- What are the differences between network attached storage (NAS) and storage attached network (SAN)?

In this section, you will learn to:

- Configure network attached storage.
- Implement file backups.
- Back up files with file history.
- Recover a file from file history.
- Backup a domain controller.
- Restore server data from a backup.

Key terms for this section include the following:

Term	Definition
Full backup	A back up that captures all of the data on a machine. A full backup is always the first backup you should run.
Incremental backup	A backup that contains all changes since the last incremental backup.
Differential backup	A backup that contains all changes since the last full backup.

Snapshot	An instant copy of an individual computer. Snapshots are normally used on virtual machines (VMs) when changes may need to be reverted.
NAS	A network storage appliance often used to store backups or other files.
SAN	A network of fast storage appliances. A SAN stores file shares and other data that needs to be accessed quickly.
Offsite storage	A location where files are stored that is away from the physical office space where the data is created. Offsite storage is part of 3-2-1 rule.
Scalability	The ability to increase or decrease data storage space.
Restoration order	Pre-planned order in which servers will be restored following a disastrous event. The order is determined by the server's importance to the company's operation.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	3.4 Explain the importance of resilience and recovery in security architecture. Backups Onsite/offsite Frequency Encryption Snapshots Recovery Replication Journaling
TestOut Security Pro	4.0 Data Security 4.1 Protect and Maintain Data files 4.1.1 Perform data backups and recovery

9.5.1 Backup Types (Lesson Video)

Transcript:

In this lesson, we'll discuss backing up data.

Backing up your data is absolutely critical. It must be done consistently, and strategically. It's also essential to verify backups to ensure that they actually work and you can restore your data.
You need to know three different types of backups. The first is the full backup, the second is the incremental backup, and the last is the differential backup. But before we dive into these, let's quickly talk about a key component used with backups called the archive bit.
The archive bit is a file attribute that is either on or off. It's used by backup systems to determine if the file has been archivedâ€""that is, has been backed up. Also, archive bit identifies if a file has been modified since the last backup. This is important when used with certain types of backups.
With that, let's explore the different types of backups.
Let's first discuss a full backup. A full backup backs up everything. It doesn't matter whether the archive bit is set or not on any file. However, as it backs up each file, it clears the archive bit to indicate that the file is backing up.
In this way, you can determine if a file has been modified at a later point in time. If you were to modify a file that has been backed up, the archive bit would be reset, indicating to the backup software that this file has been modified since the last time it was backed up.
If a file is not modified after the full backup, the archive bit is left in a cleared state. This is important because other types of backups, such as incremental, take into consideration if this archive bit has been cleared when deciding whether it should back up a file or not.
An incremental backup backs up everything since the last full backup or since the last incremental backup. To determine whether or not a file has been modified since the last full or incremental backup, it looks at the archive bit. If the archive bit is turned on, that tells the backup software that the file has been modified since the last full or incremental backup, and needs to be backed up again. Once it's backed up the file, the archive bit is cleared.
Let's run through an example. Suppose you perform a full backup of the entire file system on Monday. As a result, every file in the file system has been backed up, and the archive bit on each file is cleared. Then, on Tuesday, you perform an incremental backup. Because the incremental backup only backs up files with the archived bit set, it will only backup files that have changed since Monday. Accordingly, the incremental backup you made on Tuesday will be relatively small because it will only contain one day's worth of changes. After backing up the changed files, the incremental backup will clear the archive bit again on the files that were backed up.
If you perform another incremental backup on Wednesday, it will once again look for any files with enabled archive bits, indicating that they've been modified since either the last full backup on Monday or since the last incremental backup on Tuesday. Therefore, Wednesday's incremental backup also only contains one day's worth of changes. Likewise, if you run another incremental backup on Thursday, then only the changes that have been made since Wednesday will be backed up. The same is true on Friday.
The advantage of this strategy is that the daily incremental backups finish relatively quickly because we're only backing up one day's worth of changes. The full backup still takes some time to complete because all files are being backed up. For this reason, the full backup is usually executed over the weekend when the system is not heavily used. The incremental backups can occur each weekday. Because they don't take much time to complete, they typically don't interfere with day-to-day work.
Incremental backups have one significant drawback. The incremental backup strategy is the slowest type of backup for restoring data. For example, suppose we ran a full backup on Monday and then ran an incremental on Tuesday, Wednesday, Thursday, and Friday. Then the server crashes on Saturday, and we need to restore all the data back to the server after we've recovered from the crash.
The first thing that you must do is restore the first full backup from Monday. Then you must restore every incremental backup in the order they were created. First, you must restore Monday's incremental backup, followed by Tuesday's backup, then Wednesday, Thursday, and Friday's backups. Each backup must be restored in the proper sequence to return the system to where it was before the crash. This can take hours or even days to complete, depending how much data is involved.
Another option is to use differential backups instead of incremental. A differential backup looks for files that have been modified since the last full backup. It does this by evaluating if the archive bit has been set on the files. If the archive bit

is clear, it will not back up the file because it assumes that it has not been changed since the last full backup. If the archive bit is set, the differential backup assumes the file has been modified and needs to be backed up.
The key difference is that a differential backup does not clear the archive bit after backing up a file. Therefore, it backs up everything modified since the last full backup, but not since the last differential backup. This has advantages and disadvantages.
Suppose you perform a full backup on Monday just as with the incremental backup strategy. This clears all archive bits on all files. Then, we perform a differential backup on Tuesday and Wednesday. Because the differential backup on Tuesday does not clear any archive bits, Wednesday's differential backs up all the files that have been modified since Monday. Thursday's differential backup includes all the changes made on Monday, Tuesday, and Wednesday. Friday's differential backup includes all the changes made on Monday, Tuesday, Wednesday, and Thursday.
As you progress through the backup schedule, each differential backup takes progressively longer because it's backing up more data each time. The first differential backup completes in the same amount of time as an incremental would because we're only backing up one day's worth of data. However, each subsequent differential takes longer.
The advantage of differential backups is the speed of restoring data. With differentials, all we do is restore the full backup followed by the last differential backup. For example, if a server were to crash on Saturday, we would restore the full backup from Monday and then the last differential backup from Friday. That's all we do because the last differential backup contains a backup of every single file that has been changed since the last full backup.
You should never mix differential and incremental backups together with a full backup. If you mix full backups with incremental and differential backups, you're going to have problems because of the way these different types of backups handle the archive bit. As a result, files that should have been backed up will be missed.
Another alternative for backing up data is to create a system image. Imaging programs create a bit-level mirror of a particular hard disk or partition.
Newer versions of Windows, and all versions of Linux, include this functionality. Typically, a system image is created on a defined schedule. Because a system image backs up the entire hard disk or partition, they are rather slow to create. However, they are very fast to restore.
All you do is restore the image to the same hardware, or even to a new piece of hardware if you have a major hardware malfunction, and the system is back and available again in exactly the state it was when the image was created. This can be very useful in the event of a malware infection. Most of the time it's easier to re-image a machine that's been infected with malware rather than try to get rid of the malware.
There are other types of data to back up. For example, if you're managing a domain controller in a Windows network, then you need to backup not only the files on the server but all your active directory information as well. To do this, you can create a special type of backup on the domain controller called a system state backup.
If you are backing up sensitive information, such as your security logs, then you might want to consider the location of the backup. Instead of backing that data up to a device that can be modified in some way, find a more secure option. For example, it could be problematic if you were to back up sensitive information to a network share or perhaps a USB flash drive because of the potential of tampering. Instead, you should back up confidential information to a write-once type of media, such as a recordable DVD.
A backup is worthless unless you can successfully restore data from it. You should run periodic tests and restore from your backups in a lab environment, just to make sure that everything works should a crisis occur.
That's it for this lesson. In this lesson, we talked about backup and restore. We first discussed the importance of backing up your data. We then examined the three backup strategies: full, incremental, and differential. We then mentioned using a system image to backup data. We talked about backing up the system state on the domain controller. We discussed backing up sensitive information to write-once medium. Then we emphasized the importance of verifying backups to make sure that they actually work.

9.5.2 Backup Storage Options (Lesson Video)

Transcript:

Backups play an essential role in asset protection by ensuring the availability and integrity of an organization's critical data and systems. By creating copies of important information and storing them securely in separate locations, backups are a safety net in case of hardware failure, data corruption, or cyberattacks such as ransomware.

Many dynamics influence data backup frequency requirements, including data volatility, regulatory requirements, system performance, architecture capabilities, and operational needs. Organizations with highly dynamic data or stringent

regulatory mandates may opt for more frequent backups to minimize the risk of data loss and ensure compliance. Conversely, businesses with relatively stable data or less rigorous regulatory oversight might choose less regular backups, balancing data protection, data backup costs, and maintenance overhead. Ultimately, the optimal backup frequency is determined by carefully assessing an organization's regulatory requirements, unique needs, risk tolerance, and resources.

The need for on-site and off-site backups must be balanced, as they're crucial in securing critical data and ensuring business continuity. On-site backups involve storing data locally—in the same location as the protected systems—on devices such as hard drives or tapes to provide rapid access and recovery in case of data loss, corruption, or system failures. On the other hand, off-site backups involve transferring data to a remote location to ensure protection against natural disasters, theft, and other physical threats to local infrastructure, as well as catastrophic system loss resulting from ransomware infection.

Ransomware poses a significant threat to businesses and organizations by encrypting vital data and demanding a ransom for its release. In many cases, ransomware attacks also target backup infrastructure, hindering recovery efforts and further exacerbating the attack's impact. Perpetrators often employ advanced techniques to infiltrate and compromise both primary and backup systems, rendering them useless when needed. Organizations can implement several strategies to defend against this risk, such as maintaining air-gapped backups physically disconnected from the network, thereby actively preventing ransomware from accessing and encrypting them.

Critical recovery validation techniques play a vital role in ensuring the effectiveness and reliability of backup strategies. Organizations can identify potential issues and weaknesses in their data recovery processes by testing backups and making necessary improvements.

One common technique is the full recovery test, which involves restoring an entire system from a backup to a separate environment and verifying the fully functional recovered system. This method helps ensure that all critical components, such as operating systems, applications, and data, can be restored and function as expected.

Another approach is the partial recovery test, where selected files, folders, or databases are restored to validate the integrity and consistency of specific data subsets. Organizations can perform regular backup audits, checking the backup logs, schedules, and configurations to ensure backups are created and maintained as intended and required.

Furthermore, simulating disaster recovery scenarios, such as hardware failures or ransomware attacks, provides valuable insights into an organization's preparedness and resilience. Recovery validation strategies are essential because backups can be completed with "100% success" but mask issues until the backup set is used for recovery.

Encryption of backups is essential for various reasons, primarily data security, privacy, and compliance. By encrypting backups, organizations add an extra layer of protection against unauthorized access or theft, ensuring that sensitive data remains unreadable without the appropriate decryption key. This is particularly crucial for businesses dealing with sensitive customer data, intellectual property, or trade secrets, as unauthorized access can lead to severe reputational damage, financial loss, or legal consequences.

Copies of sensitive data stored in backup sets are often overlooked, so many industries and jurisdictions have regulations that mandate the protection of sensitive data stored in backups. Encrypting backups helps organizations meet these regulatory requirements and avoid fines, penalties, or legal actions resulting from noncompliance.

That's it for this lesson. In this lesson, we talked about data backups and backup frequency. We discussed the value of maintaining on-site and off-site backups. We talked about identifying potential issues and weaknesses by performing recovery validation. We also discussed the importance of encrypting backups.

9.5.3 Backup Types and Storage Facts

This lesson covers the following topics:

- Enterprise backups
- Data deduplication
- Backup frequency
- Snapshots
- Replication and journaling

Enterprise Backups

In an enterprise setting, simple backup techniques often prove insufficient to address large organizations' unique challenges and requirements. Scalability becomes critical when vast amounts of data must be managed efficiently. Simple backup methods may struggle to accommodate growth in data size and complexity.

Performance issues caused by simple backup techniques can disrupt business operations because they slow down applications while running and typically have lengthy recovery times. Additionally, enterprises demand greater granularity and customization to target specific applications, databases, or data subsets, which simple techniques often fail to provide.

Compliance and security requirements necessitate advanced features such as data encryption, access control, and audit trails that simplistic approaches typically lack. Moreover, robust disaster recovery plans and centralized management are essential for an enterprise backup strategy. Simple backup techniques might not support advanced features like off-site replication, automated failover, or streamlined management of the diverse systems and geographic locations that comprise a modern organization's information technology environment.

Critical capabilities for enterprise backup solutions typically include the following features:

- Support for various environments (virtual, physical, and cloud)
- Data deduplication and compression to optimize storage space
- Instant recovery and replication for quick failover
- Ransomware protection and encryption for data security
- Granular restore options for individual files, folders, or applications
- Reporting, monitoring, and alerting tools for effective management
- Integration with popular virtualization platforms, cloud providers, and storage systems

Data Deduplication

Data deduplication describes a data compression technique that optimizes storage space by identifying and eliminating redundant data. It works by analyzing data blocks within a dataset and comparing them to find identical blocks. Instead of storing multiple copies of the same data, deduplication stores a single copy. It creates references or pointers to that copy for all other instances. Deduplication can be performed at different levels, such as file-level, block-level, or byte-level. Deduplication significantly minimizes storage requirements and improves data transfer efficiency, particularly in backup and data replication processes, by reducing the amount of duplicate data stored.

Backup Frequency

Many dynamics influence data backup frequency requirements, including data volatility, regulatory requirements, system performance, architecture capabilities, and operational needs. Organizations with highly dynamic data or stringent regulatory mandates may opt for more frequent backups to minimize the risk of data loss and ensure compliance. Conversely, businesses with relatively stable data or less stringent regulatory oversight might choose less frequent backups, balancing data protection, data backup costs, and maintenance overhead. Ultimately, the optimal backup frequency is determined by carefully assessing an organization's regulatory requirements, unique needs, risk tolerance, and resources.

Snapshots

Snapshots play a vital role in data protection and recovery, capturing the state of a system at a specific point in time. Virtual Machine (VM), filesystem, and Storage Area Network (SAN) snapshots are three different types, each targeting a particular level of the storage hierarchy.

VM snapshots, such as those created in VMware vSphere or Microsoft Hyper-V, capture the state of a virtual machine, including its memory, storage, and configuration settings. This allows administrators to roll back the VM to a previous state in case of failures, data corruption, or during software testing.

Filesystem snapshots, like those provided by ZFS or Btrfs, capture the state of a file system at a given moment, enabling users to recover accidentally deleted files or restore previous versions of files in case of data corruption.

SAN snapshots are taken at the block-level storage layer within a storage area network. Examples include snapshots in NetApp or Dell EMC storage systems, which capture the state of the entire storage volume, allowing for rapid recovery of large datasets and applications.

Replication and Journaling

Replication and journaling are data protection methods that ensure data availability and integrity by maintaining multiple copies and tracking changes to data. Replication involves creating and maintaining exact copies of data on different storage systems or locations. Organizations can safeguard against data loss due to hardware failures, human errors, or malicious attacks by having redundant copies of the data. In the event of a failure, the replicated data can be utilized to restore the system to its original state.

A practical example of replication is database mirroring, where an organization maintains primary and secondary mirrored databases. Any changes made to the primary database are automatically replicated to the secondary database, ensuring data consistency and availability if the primary database encounters any issues.

On the other hand, journaling records changes to data in a separate, dedicated log known as a journal. Organizations can track and monitor data modifications and revert to previous states if necessary. Journaling is beneficial for data recovery in system crashes. After completing the full system backup, it enables the system to identify and undo any incomplete transactions that might have caused inconsistencies or replay transactions. This provides greater granularity for restores and greatly minimizes data loss. A practical example of journaling is using file system journaling, such as the Journaled File System (JFS) or the New Technology File System (NTFS), with journaling enabled. These file systems record all changes made to files, allowing for data recovery and consistency checks after unexpected system shutdowns or crashes.

Remote journaling, SAN replication, and VM replication are advanced data protection methods that maintain data availability and integrity across multiple locations and systems. Remote journaling creates and maintains a journal of data changes at a separate, remote location, allowing for data recovery and ensuring business continuity in case of local failures, natural disasters, or malicious attacks.

SAN replication duplicates data from one SAN to another in or near real-time, providing redundancy and protection against hardware failures, human errors, or data corruption. This technique involves synchronous replication, which guarantees data consistency, and asynchronous replication, which is more cost-effective but slightly less stringent in consistency.

Meanwhile, VM replication creates and maintains an up-to-date copy of a virtual machine on a separate host or location, ensuring that a secondary VM can quickly take over the workload in the event of a primary VM failure or corruption. By implementing these methods, organizations can bolster their data protection strategies, safeguarding against various risks and ensuring the availability and integrity of their critical data and systems.

9.5.4 Configure Network Attached Storage (Demo Video)

Transcript:

Network attached storage, or NAS, is a file-level storage device on your network. These devices can be useful when you share data or even back it up. Generally, there'll be several drives in the NAS device for redundancy. But if you want to make sure data isn't lost due to drive failure, a cloud sync is suggested.

TrueNAS, which is also known as free NAS, is open-source software. You can install this software on a physical server or a virtual machine.
TrueNAS makes it very easy to set up, as all we've done up to this point is install it, set an IP, and set a root password. In order to use any disks for storage, we must configure a storage pool. To do so, go to 'Storage' and then 'Pools'. Then click 'ADD' and 'CREATE POOL'. Next, we're going to give it a name and select the two available disks we have. Most likely, a production NAS will have more storage and more available disks then what we're showing. Since there are only two disks, we're going to set up a 'Mirror' vs. Stripe. Click 'CREATE', 'Confirm', and 'CREATE POOL'.
Now that our pool is set up, we must create a Windows share. Go to 'Sharing' and then 'Windows Shares (SMB)'. The drop-down menu at the top of the main folder will be selected since that was the name set on the storage pool. Nothing else is needed, but you could add a description if you'd like for documentation. Click 'SUBMIT'. A box will appear asking you to enable the SMB service since it wasn't on before.
Next, a user needs to be set up so some form of authentication can happen to access this newly created share. We'll set up a basic user under 'Accounts' and then 'Users'. Click 'ADD'. Our name here will be 'backup'. The same name will be used for the username as well. Enter a password and confirm it. As we scroll down, we need to give this user permission to our new share directory. Drop down the folder and select 'main'. All of the home directory permissions are fine for now, so we'll leave them. One thing is for certain - this user doesn't require shell login, so we want to disable this for security purposes. If you click over here and select 'nologin', it'll take care of this problem. Click 'SUBMIT' when finished. Our configuration is complete on our NAS, so were going to hop over to our Windows machine to configure the rest.
In order to have this NAS easily accessible, we're going to map it as a network drive. To do so, go to 'File Explorer'. As we expand this, we're going to go to 'This PC'. Next, the 'Computer' tab at the top will give us the option to map a network drive. Select a drive letter of your choosing. The path in the folder will be the IP address or DNS name for the NAS. We're going to use the IP as we don't have DNS set up for this right now. Type '\\192.168.30.106', as this was the IP of our NAS. Now click 'Browse'. It'll take a second, and you might have to click on the device for the username and password prompt to come up. Enter the username and password we set up for the backup user. The key thing is to check 'Remember my credentials', otherwise this mount will be asking for the password every time your computer reboots. Click 'OK' and then select the 'backup' folder. If you notice, TrueNAS creates a folder with the same username as the user, unless changed. Once we click 'Finish', our new mount will be mounted as the N: drive. Don't worry about the rest of the files in this directory, as this pertains to the username associated with the TrueNAS side. Since we may have multiple computers backing up their data here, we'll just name a folder 'computer_1'.
Now we can go set up some backup jobs. You do have the ability to use other backup solutions. However, we're just going to use the built-in File History. When we type 'backup' in the search bar here, it brings us to our backup settings. Notice when we click on 'Add a drive', it says no usable drives found. This doesn't mean it's broken. Typically, this menu looks for secondary or removable drives that are local. If we select 'More options' and 'See advanced settings', we get the option to map file history to a network location. We can then navigate to our mapped drive by going to 'This PC', clicking on the 'N:' drive, and going to the 'computer_1' folder. Click 'OK' and then after that we should be able to turn on our 'File History' now.
That's it for this demo. In this demo, we showed you how to configure a NAS, set up an SMB share, and configure a mapped network drive for File History backups.

9.5.5 Implementing File Backups (Demo Video)

Transcript:

In this demonstration, we're going to look at two ways to back up files on a Windows system—using File History and using the legacy Backup and Restore utility.

Let's take a look at setting up File History first. File History saves copies of your files so they can be recovered later if needed. Using the Windows search button, I'll look for file history and click to start it. As you can see, it's currently turned

off. There's only one button to choose from. Once it's turned on, you can select Run now to start an immediate backup of the listed locations. As you can see, the H: drive is currently selected as the storage device.
To the left, additional options are available. In addition to the Restore personal files option, which is used for retrieving copies after they've been backed up, there's Select drive. When clicked, the available devices are listed. In this case, only the H: drive is available. There's also an option to add a network location.
Another important setting is Exclude folders. Currently, the Pictures library is excluded from copies being kept. The Add and Remove buttons can be used to change this list. In Advanced settings, we can change how often copies are made and how many versions to keep. The defaults are Every hour and Forever, respectively.
The legacy Backup and Restore tool is designed to hold copies of data or an entire system as a disk image. It's recommended that the device holding the backups be external, or at least on a different storage device than the C: drive. In this case, I have a second device prepared. I'll browse to the Backup and Restore utility found under Control Panel. The tool's full name is Backup and Restore (Windows 7) since this is a legacy tool from the Windows 7 days. Once launched, I'll select Set up backup and then select the appropriate device. The H: drive is the device I intend to perform backups to, so I don't need to make any changes. I could, if necessary, click on the Save on a network button and browse to a shared location for storage. I'll leave it as the H: drive and click Next.
At this point, the system wants me to choose which files and folders to back up. Since the default settings are good for our purposes in this demo, I'll leave it on Let Windows choose and click Next. On the next screen, we see a review of the options we've selected and a new Change schedule link. Currently, the backup is run on Sunday at 7:00 PM, which is good for our needs. To finish the configuration, we click Save settings and run backup.
That's it for this demonstration on backups. We covered two ways to back up files. First, we looked at backing up using File History, and then we looked at the legacy Windows 7 Backup and Restore utility.

9.5.6 Back Up Files with File History (Simulation)

Scenario

You have recently installed a new Windows 10 computer. To protect valuable data, you need to implement file history backups on this computer.

In this lab, your task is to configure automatic backups for the Exec computer as follows:

- Save the backup to the **Backup (E:)** volume.
- Back up files **daily** .
- Keep backup files for **six months** .
- Back up the entire **Data (D:)** volume.
- Make a backup now.

Explanation

Complete this lab as follows:

1. Access the File History Backup options.
   a. Right-click **Start** and then select **Settings** .
   b. Select **Update & Security** .
   c. From the left pane, select **Backup** .

Configure and run a file history backup plan.

From the right pane, select **Add a drive** .

Select **Backup (E:)** .

Under *Automatically back up my files* , move the switch to **On** .

Select **More options** .

Under *Back up my files* , use the drop-down menu to select **Daily** .

Under *Keep my backups* , use the drop-down menu to select **6 months** .

Under *Back up these folders* , select **Add a folder** .

Double-click the **Data (D:)** volume and then select **Choose this folder** .

Select **Back up now** .

Wait for the backup to complete.

9.5.7 Recover a File from File History (Simulation)

Scenario

Susan produces your organization's monthly magazine. While working on an upcoming issue, Susan accidentally deleted significant portions of the layout image. She also made extensive changes to the cover artwork but has now been asked to discard the changes and use the original artwork.

Susan has asked you to help her recover older versions of her files in the Pictures library so she can still meet her publishing deadline.

In this lab, your task is to complete the following:

Using the Settings app, access the program needed to restore files from a current backup.

From the File History dialog, restore the following files:

File	File Version to Restore
Pictures\Layouts\June2023_Issue.jpg	Thursday, March 16, 2023 11:15 AM
Pictures\Images\coverart.jpg	Thursday, March 16, 2023 12:15 PM

Explanation

Complete this lab as follows:

Access the File History options using the Settings app.

Right-click **Start** and then select **Settings** .

Select **Update & Security** .

From the left pane, select **Backup** .

Make sure *Automatically back up my files* is set to **On** .

Select **More options** .

Scroll to the bottom of the *Backup options* dialog and select **Restore files from a current backup** .

Maximize the window for better viewing.

Restore the June2023_Issue.jpg file.

From the bottom of the File History dialog, select the **Previous version** button (left arrow) to navigate to the backups captured on **Thursday, March 16, 2023 11:15 AM** .

Double-click **Pictures** .

Double-click **Layouts** .

Select the **June2023_Issue.jpg** file.

Select the green **Restore to original location** arrow located at the bottom center.

Select **Replace the file in the destination** .
The Layouts folder where the file was restored is opened.

From the Layouts folder, right-click the **June2023_Issue.jpg** file and then select **Properties** .

Verify that the file is **115.44 MB** in size and was last modified on **March 16, 2023 at 11:15:12 AM** .

Select **OK** .

Close the Layouts window.

Restore the Coverart.jpg file.

From the top left of the *File History* dialog, select the **up arrow** to navigate to the **Home\Pictures** folder.

Select the **Previous version** button at the bottom to navigate to the backups captured on **Thursday, March 16, 2023 12:15 PM** .

Double-click **Images** .

Select the **coverart.jpg** file.

Select the green **Restore to original location** arrow located at the bottom center.

Select **Replace the file in the destination** .

Right-click the **coverart.jpg** file and select **Properties** .

Verify that the file is **1.09 MB** in size and was last modified on **March 16, 2023 at 12:15:12 PM.**

Select **OK** .

9.5.8 Backup a Domain Controller (Demo Video)

Transcript:

In this demo we are going to do a backup of our domain controller on a Windows Server. To start, you need to install the Windows backup feature. The first thing we need to do is go to Manage, click Add Roles and Features.

Now we're going to just select Default, Next, Next, past everything until we get to features. Then we're going to scroll down and go to Windows Server Backup. Select it, click next. On the confirm window I can click Install. Then that's going to go ahead and install and that may take a few minutes.
Once that's installed, we can go to our tools all the way down, scroll down to Windows Server Backup. Using Windows Server Backup you can schedule regular server backups, or you can schedule a single backup.
In this case, we're going to just choose Backup Once. However, a good disaster recovery program would do regular backups. We'll click backup once since were not scheduling a backup. Since we have not created any scheduled backups before, you must click different options.
Let's go ahead and click Custom. Click Next, we're going to click add items and we're going to select the System State. Bare Metal Recovery, will backup all the critical volumes on the computer. It will backup the operating system and all the data volumes if you are doing a bare metal recovery, also sometimes known as an all critical backup, the backup can't be saved on any of the volumes that are being backed up. As well with the system state backup, we can't save the backup on the C drive because that's where the system state exists.
So the system state includes the registry key files, Active Directory and the SYSVOL. We need to have some other place to store this backup. I've connected an external drive to this system currently, so I'm going to click OK.
Click next and you actually also have the ability to save things to remote share folders. If you have some shared storage on your network, you could actually go save your backup there.
We're going to select a local drive since it's a drive I have plugged into this local machine. It's my F drive labeled Backup. We're going to click Next, and Backup. Okay, so once this backup finishes, which it will take a while, we'll have a good backup of our active directory and the SYSVOL.
If we need to restore, we can come back to this backup later to restore the main domain controller.
In this demonstration we installed Windows server backup on your Windows Server and then backed up our domain controller.

9.5.9 Restoring Server Data from Backup (Demo Video)

Transcript:

In this demonstration, we'll explore the process of recovering user data on a server.

In our File Explorer window, let's navigate to the Desktop, where we can find the Shares folder that we previously created.

Now, let's delete this folder, making it disappear. However, imagine that later on, we realize we need it back. To retrieve it, we'll have to restore it from a backup. To initiate this process, let's go to Tools > Windows Server Backup.
In the Messages Box, we can see the available backup options. Let's click on the one we want to use and review its information. Once we're satisfied, click OK. Next, we'll click on "Recover" and then proceed with "Next."
Here, we can verify our selection to ensure it's the correct backup. Since it's the only one available, let's proceed by clicking "Next."
Note that we have several recovery options. We can recover files or folders, and if this were a Hyper-V Server, we could recover an entire virtual machine if needed. It's also possible to recover entire volumes.
Now, let's talk about applications recovery. If you have backed up a server with installed applications like Exchange or SharePoint, you can restore the entire application without having to reinstall it from scratch. However, you only need to recover the data in this case. This can be useful for transferring an application from one server to another using the backup.
The last option is to recover specific files and folders. Let's click "Next."
So, we'll navigate to the specific folder we want to recover.
After selecting it, click "Next," and then choose to restore it to the original location. Although you have the option to save it elsewhere, we want it back in its original place.
Now, let's create copies of both versions just as a precautionary measure. There are several reasons not to overwrite existing versions.
If you're restoring a file that someone claims is missing, and they provide the wrong filename, you could accidentally overwrite a file they intended to keep. This could lead to future problems.
It's a wise practice to create copies to avoid data loss or accidental overwrites. In such cases, you'd have to go back and recover even more data. Let's proceed by selecting "Next" and then "Recover."
Now, it confirms that the process is complete. Let's close and minimize the windows. You can now see that the folder has been successfully restored to its original location.
In this demonstration, we walked you through the process of restoring data using Windows Server 2022 Backup, illustrating how to utilize Windows Restore Data effectively.

9.5.10 Backup a Domain Controller (Simulation)

Scenario

You are the IT administrator for a small corporate network. You need to back up the system state of your domain controllers so that, in the event of a disaster, Active Directory is backed up. You want to configure regular backups on CorpDC4.

In this lab, your task is to perform the following using Windows Server Backup on CorpDC4:

Create a regular backup schedule for the CorpDC4 server using the following settings:

Backup items: **System State**

Backup schedule: **once per day at 1:00 a.m.**

Backup location: **\\CorpFiles\Backup**

Take an immediate backup using the following settings:

Backup items: **System State and C: drive**

Backup location: **\\CorpFiles\Backup**

Explanation

Complete this lab as follows:

Access Windows Server Backup on the CorpDC4 server.

From Hyper-V Manager, select **CORPSERVER2** .

From the Virtual Machines pane, double-click **CorpDC4** .

From the Server Manager menu bar, select **Tools** > **Windows Server Backup** .

Maximize the window for better viewing.

Create a backup schedule.

From the left pane, select **Local Backup** .

From the far right pane, under Actions, select **Backup Schedule** .

Select **Next** in the wizard.

From the Select Backup Configuration window, select **Custom** , and then select **Next** .

Select **Add items** .

Select **System state** , and then select **OK** .

Select **Next** .

Make sure **Once a day** is selected.

Using the *Select time of day* drop-down list, select **1:00 AM** , and then select **Next** .

Select **Back up to a shared network folder** , and then select **Next** .

Read the warning message, and then select **OK** .

In the Location field, enter **\\CorpFiles\Backup** and select **Next** .

Select **Finish** .

Select **Close** .

Perform an immediate backup.

From the far right pane, under Actions, select **Backup Once** .

From the Backup Options window, select **Different options** , and then select **Next** .

From the Select Backup Configuration window, select **Custom** , and then select **Next** .

Select **Add items** .

Select **System state** .

Select **Local Disk (C:)** .

Select **OK** .

Select **Next** .

Select **Remote shared folder** , and then select **Next** .

In the Location field, enter **\\CorpFiles\Backup** and select **Next** .

Select **Backup** to start the backup.

When the backup is complete, select **Close** .

9.5.11 Practice Questions (Section Quiz)

q_bkp_stor_backup-frequency_secp8

You are the IT manager of a financial services firm. Your company deals with highly dynamic data and stringent regulatory mandates.

You are tasked with determining the optimal backup frequency for your company's data.

Which of the following factors should be your top priority when deciding on the backup frequency?

Answers:

***The volatility of the company's data.**

The company's office hours.

The usability of the backup software's interface.

The brand popularity of the backup solution.

Explanation:

The volatility of the company's data is a crucial factor to consider when deciding on the backup frequency. Companies with highly dynamic data may need more frequent backups to minimize the risk of data loss.

The company's office hours do not directly impact the backup frequency. While backups are ideally scheduled during non-peak hours to minimize disruption, the frequency of backups should primarily be determined by the volatility of the data and regulatory requirements.

The usability of the backup software's interface does not impact the backup frequency and should not be a factor in this decision.

The brand popularity of the backup solution does not impact the backup frequency and should not be a factor in this decision. The focus should be on the specific needs of the company and how well the backup solution can meet these needs.

q_bkp_stor_data-deduplication_01_secp8

An enterprise seeks to optimize its backup storage space due to the increasing amounts of data it handles daily. The company wants to ensure it is not storing redundant copies of the same data, which consumes valuable storage resources.

Which technique should the company implement to solve this issue?

Answers:

***Data deduplication**

Data journaling

Data encryption

Data replication

Explanation:

Data deduplication is a data compression technique that reduces storage requirements by eliminating redundant copies of the same data. Instead of storing multiple copies of the same data, deduplication stores a single copy and creates references to that copy for all other instances.

Data journaling is a method used to keep track of changes made to the data. Data journaling is beneficial for data recovery, but does not help optimize storage space by eliminating redundant data.

While data encryption is critical for data security and compliance, it does not directly contribute to optimizing storage space.

Data replication involves creating and maintaining exact copies of data on different storage systems or locations, which can consume more storage space.

q_bkp_stor_data-deduplication_02_secp8

Which of the following statements about data deduplication is correct?

Answers:

Data deduplication increases the amount of storage space required.

Data deduplication can only be performed at the file-level.

Data deduplication reduces data transfer efficiency in backup and data replication processes.

***Data deduplication is a data compression technique that eliminates redundant data and optimizes storage space.**

Explanation:

Data deduplication is a data compression technique that works by identifying and eliminating redundant data. Instead of storing multiple copies of the same data, deduplication stores a single copy and creates references to that copy for all other instances. This process optimizes storage space and improves data transfer efficiency.

Data deduplication does not increase the amount of storage space required. On the contrary, it reduces the amount of storage space required by eliminating redundant data.

Data deduplication can be performed at different levels depending on the specific needs and capabilities of the system. This includes file-level deduplication, block-level deduplication, and byte-level deduplication.

By reducing the amount of redundant data stored, data deduplication can significantly improve the efficiency of data transfer in backup and data replication processes. This can result in faster backups and less network bandwidth usage.

q_bkp_stor_enterprise-backup_01_secp8

You are the IT manager of a large corporation. Your company has been experiencing rapid growth, and the current backup techniques are proving insufficient to address the unique challenges and requirements of the organization.

You are tasked with implementing a new enterprise backup solution.

Which of the following would be the MOST effective approach?

Answers:

Implement a simple backup method that backs up all data once per week.

***Implement an enterprise backup solution that supports various environments and offers data deduplication and compression.**

Implement a backup solution that only focuses on the most critical data and ignores less important data.

Implement a backup solution that backs up all data once per month to minimize disruption to business operations.

Explanation:

An enterprise backup solution that supports various environments and offers data deduplication and compression would address the unique challenges and requirements of a large organization. It would provide scalability, minimize disruption to business operations, meet compliance and security requirements, and offer robust disaster recovery plans and centralized management.

While implementing a simple backup method that backs up all data once per week may be simpler and less costly, it may not be sufficient for a large organization with vast amounts of data and unique challenges. It may also result in lengthy recovery times and lack the advanced features necessary for compliance and security requirements.

While it is important to prioritize critical data, ignoring less-important data could still result in significant data loss and potential operational and compliance issues. An effective backup solution should aim to protect all data, not just the most critical.

While it may minimize disruption to business operations, backing up all data only once per month could result in significant data loss in the event of a disaster or system failure. An effective backup solution should aim for more frequent backups to minimize the risk of data loss.

q_bkp_stor_enterprise-backup_02_secp8

You are the IT manager of a large corporation. Your company has been using a traditional backup method that backs up all data once per week.

However, with the growth of the company and the increase in data, this method is causing performance issues and proving insufficient. You are considering implementing an enterprise backup solution.

Which of the following factors should be your top priority when choosing a new backup solution?

Answers:

The scalability of the backup solution.

***The ability of the backup solution to minimize performance disruptions during backup operations.**

The brand popularity of the backup solution.

The usability of the backup solution interface.

Explanation:

The ability of the backup solution to minimize performance disruptions during backup operations should be the top priority in this scenario. The current backup method is causing performance issues, so it's crucial to choose a solution that can perform backups efficiently without significantly impacting system performance.

While scalability is an important factor to consider when choosing a new backup solution, it is not the top priority in this scenario. The main issue at hand is the performance disruptions caused by the current backup method.

While a popular brand may indicate a reliable and well-tested product, it is not the top priority in this scenario. The specific features and capabilities of the solution and how well they meet the company's needs should be the focus, particularly the need to minimize performance disruptions.

The usability of the backup solution interface does not impact the functionality or effectiveness of the solution and should not be a top priority. The main issue at hand is the performance disruptions caused by the current backup method.

q_bkp_stor_filesystem-snapshots_secp8

A large organization is implementing a data protection strategy and considering the use of snapshots. The company has a complex IT environment with a mix of physical servers, virtual machines, and cloud-based services.

The primary concern is the ability to recover individual files or previous versions of files in case of accidental deletion or data corruption.

Which type of snapshot would be MOST suitable for this organization?

Answers:

Virtual Machine (VM) snapshots

***Filesystem snapshots**

Storage Area Network (SAN) snapshots

Cloud-based snapshots

Explanation:

Filesystem snapshots is the correct answer. Filesystem snapshots, like those provided by ZFS or Btrfs, capture the state of a file system at a given moment. This allows users to recover accidentally deleted files or restore previous versions of files in case of data corruption. This makes them the most suitable option for the organization's primary concern.

While VM snapshots capture the state of a virtual machine, including its memory, storage, and configuration settings, they are not the best option for recovering individual files or previous versions of files. They are more suitable for rolling back the entire VM to a previous state in case of failures or during software testing.

SAN snapshots capture the state of the entire storage volume, allowing for rapid recovery of large datasets and applications. However, they are not as granular as filesystem snapshots and may not be the best option for recovering individual files or previous versions of files.

Cloud-based snapshots are similar to VM snapshots but are taken in a cloud environment. They capture the state of a cloud-based virtual machine or storage volume. While they can be useful in a cloud environment, they may not provide the granularity needed for recovering individual files or previous versions of files.

q_bkp_stor_remote-journaling_secp8

A large multinational corporation is implementing a data protection strategy. The company has a complex IT environment with a mix of physical servers, virtual machines, and cloud-based services.

The primary concern is the ability to track and monitor data modifications and revert to previous states if necessary, especially in the event of local failures, natural disasters, or malicious attacks.

Which type of journaling would be MOST suitable for this organization?

Answers:

File system journaling

Database journaling

***Remote journaling**

Application-level journaling

Explanation:

Remote journaling is the correct answer. Remote journaling creates and maintains a journal of data changes at a separate, remote location, allowing for data recovery and ensuring business continuity in case of local failures, natural disasters, or malicious attacks. This makes it the most suitable option for the organization's primary concern.

File system journaling, such as the Journaled File System (JFS) or the New Technology File System (NTFS), records all changes made to files, allowing for data recovery and consistency checks after unexpected system shutdowns or crashes. While it is useful for tracking and monitoring data modifications, it may not provide the necessary protection in the event of local failures, natural disasters, or malicious attacks.

Database journaling records changes to data within a database. While it can be useful for tracking and monitoring data modifications within a database, it may not provide the necessary protection in the event of local failures, natural disasters, or malicious attacks.

Application-level journaling records changes to data within a specific application. While it can be useful for tracking and monitoring data modifications within a specific application, it may not provide the necessary protection in the event of local failures, natural disasters, or malicious attacks.

q_bkp_stor_replication-secp8

In the context of data protection and recovery, which of the following statements about replication is correct?

Answers:

Replication is a data compression technique that optimizes storage space by identifying and eliminating redundant data.

Replication involves creating and maintaining different versions of data on the same storage system.

Replication can increase the risk of data loss due to hardware failures, human errors, or malicious attacks.

***Replication involves creating and maintaining exact copies of data on different storage systems or locations.**

Explanation:

Replication involves creating and maintaining exact copies of data on different storage systems or locations. Replication is a data protection method that involves creating and maintaining exact copies of data on different storage systems or locations.

Replication is a data compression technique that optimizes storage space by identifying and eliminating redundant data is incorrect. The process described here is data deduplication, not replication. Replication involves creating and maintaining exact copies of data, not eliminating redundant data.

Replication involves creating and maintaining different versions of data on the same storage system is incorrect. Replication involves creating and maintaining exact copies of data on different storage systems or locations, not different versions of data on the same storage system.

Replication can increase the risk of data loss due to hardware failures, human errors, or malicious attacks is incorrect. By having redundant copies of the data, replication can actually safeguard against data loss due to various factors including hardware failures, human errors, or malicious attacks.

q_bkp_stor_san-snapshots_secp8

A large multinational corporation is implementing a data protection strategy. The company has a complex IT environment with a mix of physical servers, virtual machines, and cloud-based services.

The primary concern is the ability to rapidly recover large datasets and applications in the event of a major system failure or data corruption.

Which type of snapshot would be MOST suitable for this organization?

Answers:

Virtual Machine (VM) snapshots

Filesystem snapshots

***Storage Area Network (SAN) snapshots**

Cloud-based snapshots

Explanation:

Storage Area Network (SAN) snapshots is the correct answer. SAN snapshots are taken at the block-level storage layer within a storage area network. They capture the state of the entire storage volume, allowing for rapid recovery of large datasets and applications. This makes them the most suitable option for the organization's primary concern.

VM snapshots capture the state of a virtual machine, including its memory, storage, and configuration settings. While they can be useful for rolling back the entire VM to a previous state in case of failures or during software testing, they may not be the most efficient for rapid recovery of large datasets and applications.

Filesystem snapshots, like those provided by ZFS or Btrfs, capture the state of a file system at a given moment. They are excellent for recovering accidentally deleted files or restoring previous versions of files in case of data corruption. However, they may not be the best option for rapid recovery of large datasets and applications.

Cloud-based snapshots are similar to VM snapshots but are taken in a cloud environment. They capture the state of a cloud-based virtual machine or storage volume. While they can be useful in a cloud environment, they may not provide the rapid recovery of large datasets and applications that SAN snapshots can offer.

q_bkp_stor_vm-replication_secp8

A large software development company is implementing a data protection strategy. The company heavily relies on virtual machines for their development and testing environments.

The primary concern is the ability to quickly recover and resume work in the event of a primary VM failure or corruption.

Which data protection method would be MOST suitable for this organization?

Answers:

File system journaling

Database mirroring

SAN replication

***VM replication**

Explanation:

VM replication is the correct answer. VM replication creates and maintains an up-to-date copy of a virtual machine on a separate host or location, ensuring that a secondary VM can quickly take over the workload in the event of a primary VM failure or corruption. This makes it the most suitable option for the organization's primary concern.

File system journaling records all changes made to files, allowing for data recovery and consistency checks after unexpected system shutdowns or crashes. While it is useful for tracking and monitoring data modifications, it may not provide the quick recovery of a virtual machine environment that the company needs.

Database mirroring involves maintaining primary and secondary mirrored databases. Any changes made to the primary database are automatically replicated to the secondary database. While it ensures data consistency and availability if the primary database encounters any issues, it may not provide the quick recovery of a virtual machine environment that the company needs.

SAN replication duplicates data from one SAN to another in or near real-time, providing redundancy and protection against hardware failures, human errors, or data corruption. While it is beneficial for large datasets and applications, it may not provide the quick recovery of a virtual machine environment that the company needs.

10.0 Protocol, App, and Cloud Security

10.1 Host Virtualization

As you study this section, answer the following questions:

What is virtualization?

What is the difference between a virtual machine and a hypervisor?

What are the advantages of virtualization?

How do you secure a container?

In this section, you will learn to:

Use VMWare Player.

Use Hyper-V.

Create virtual machines.

Use Windows Sandbox.

Create containers.

Secure containers.

Key terms for this section include the following:

Term	Definition
Physical machine	The physical computer with hardware, such as the hard disk drive(s), optical drive, RAM, and motherboard.

Virtual machine	A software implementation of a computer that executes programs like a physical machine.
Virtual hard disk (VHD)	A file that is created within the host operating system and simulates a hard disk for the virtual machine.
Hypervisor	A thin layer of software that resides between the guest operating system and the hardware. It creates and runs virtual machines.
Load balancing	A technique that disperses a workload between two or more computers or resources to achieve optimal resource utilization, throughput, or response time.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
TestOut Security Pro	3.3 Implement virtualization 3.3.1 Create virtual machines 3.3.2 Create virtual switches 5.2 Assessment techniques 5.2.3 Scan for vulnerabilities
CompTIA Security+ SY0-701	2.3 Explain various types of vulnerabilities. Virtualization Virtual machine (VM) escape Resource reuse 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Segmentation 3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts Network infrastructure Logical segmentation Containerization

	Virtualization 3.2 Given a scenario, apply security principles to secure enterprise infrastructure. Infrastructure considerations Load balancer 3.4 Explain the importance of resilience and recovery in security architecture. High availability Load balancing vs. clustering 4.1 Given a scenario, apply common security techniques to computing resources. Sandboxing 4.3 Explain various activities associated with vulnerability management. Identification methods Vulnerability scan

10.1.1 Host Virtualization Overview (Lesson Video)

Transcript:

Let's spend a few minutes talking about virtualization and virtual network components.

Virtualization is a very important aspect of modern computing. But before we talk about what virtualization is and how it works, we first need to look at the way things have traditionally been done.
In the traditional computing model, we have one operating system, or OS, installed on one hardware device. In this example, we have hardware that consists of our CPU, storage, and memory resources. We need an operating system to run these resources, which could be Windows, Linux, or even macOS. Either way, we have one hardware device being managed by one operating system.
The operating system's role is to provide services for all the applications that run on the hardware device so that they can utilize the memory, storage, and CPU resources efficiently. Here we have App1, App2, App3, and App4. Each app makes its own requests for hardware resources, and then the OS makes that happen. For example, let's suppose you're going to install a new server in your data center. The first thing you'd do is order your server hardware and then you'd pick an operating system. When the server comes, you'd install a server operating system on the hardware. The operating system has full reign over all the resources available on the server hardware, including RAM, processor time, storage devices, network interfaces, and so on. Finally, you'd install applications on top of that operating system that would interact with system resources.
There's a fundamental problem with doing things this wayâ€”it's terribly inefficient. Usually, applications that run on the OS don't fully utilize all the hardware resources all the time. This is often true on a server system, and you find out that a lot of times your computing resources are actually underutilized. For example, you may see your CPU utilization hovering around 10% most of the time. You may also see that your memory utilization is likewise hovering at around 20%. This means 80-90% capacity is still available to perform additional computing tasks.

Servers are expensive, and wasted capacity means wasted dollars. Many times, servers are purchased for a specific purpose such as running web servers for individual apps. This can lead to server sprawl for the many underutilized servers This sucks up lots of power, puts out tons of heat, and costs an immense amount of money.
But there's a way to overcome this and consolidate all those servers into just a few, compact ones. That's where virtualization comes in.
Virtualization enables you to run multiple servers on a single physical server, called a host, through hardware virtualization. When you do this, each independent operating system or virtual machine thinks it has all the hardware resources it needs and runs in its own little isolated container. So instead of the many underutilized servers in traditional networking, with virtualization we can put many servers together on one hardware chassis to fully utilize CPU, RAM, disk, and network subsystems.
Virtualization increases IT agility, allows for greater flexibility, delivers increased performance, and allows you to scale up quickly while enjoying significant cost savings. We'll get to some more important benefits in just a minute.
Nowadays, we can virtualize just about anythingâ€”operating systems, storage, apps, networking, desktops, and more.
Virtualization can also be enabled in the cloud where much of the computing can be done remotely without you having to build and maintain your own data center. It also allows companies to build their own private clouds in their data centers to virtually deliver their homemade apps to their corporate users. Now users can use just about any device to securely access their workloads remotely at any place, anytime, anywhere. The power of virtualization is driving an immense, global, and increasingly mobile workforce.
Virtualization starts with you installing a thin piece of software called a hypervisor, which decouples the virtual machines, or VMs, from the hardware and dynamically allocates resources as the virtual machines request them. Once the hypervisor is installed, you can then create virtual machines with their own operating system and apps.
Notice in this diagram we have our memory, storage, and CPU just like before. But instead of installing an operating system directly onto the host, we install a hypervisor to manage it.
On top of the hypervisor, we create virtual machines by allocating CPU, RAM, and storage. Generally, the more hardware you have on the host, the more virtual machines you can build. These physical servers that host multiple virtual machines have lots of processors and lots of RAM, and they're usually connected to an immense storage area network, or SAN, that's made to be fault tolerant.
Notice that each VM has its own OS and applications in an isolated container. Each VM makes calls to use each piece of hardware, and the hypervisor facilitates those requests. You can install just about any OS inside of a VM and then run apps built for that OS.
Before we go on, there are three kinds of hardware virtualization that you need to be familiar with.
The first type is called full virtualization. In full virtualization, the virtual machine completely emulates a real, physical host. This is good because it allows most operating systems and applications to run within that virtual machine without being modified in any way. The hypervisor fully decouples the operating system from the hardware. There are two types of full virtualization: bare-metal hypervisors (type 1) and hosted hypervisors (type 2). We'll learn more about these in just a minute.
Another form of virtualization is called partial virtualization. In partial virtualization, some virtual machine components are virtualized while others aren't. In other words, the OS uses some virtual components and some physical components while it runs. It's important to note that an operating system can only run in a partial virtualization environment if that operating system has been specifically modified to do so.
The last type of virtualization is called paravirtualization. In paravirtualization, the hardware isn't virtualized at all. In other words, all the guest operating systems running on the hypervisor actually access various hardware resources in the physical devices directly. It doesn't virtualize any of the components. To do this, the guest operating systems run in isolated domains on the same physical hardware, which basically simulates running on separate systems. For an operating system to run on a paravirtualization environment, it must be specially modified to do so.
As you can see, a hypervisor is a fundamental component in any virtualization implementation.
There are several different hypervisors that you can choose from, and they generally fall within two main categories: type 1 and type 2.
As we mentioned, type 1 hypervisors are installed directly onto the hardware and allow you to build VMs. This type is used in data centers to virtualize servers. Examples of type 1 hypervisors include VMware vSphere, Microsoft Hyper-V, Linux KVM, Citrix Hypervisor, Xen, and Oracle VM. These are enterprise-class hypervisors for serious, large-scale virtualization deployments that provide an array of management tools and feature-rich benefits.
Alternatively, we have type 2 hypervisors. Since type 2 hypervisors are hosted and run on top of a regular operating system, they allow you to get a test environment up and running quickly without having to buy huge systems. Examples of type 2 hypervisors are VMware Workstation, Oracle VirtualBox, and Microsoft Hyper-V which is built into Windows 8.1 and 10.

All these hypervisors perform basically the same role that we talked about before. They allow you to install multiple operating systems on a single physical server.
There are many benefits to implementing virtualization in your environment. The biggest drivers are reduced expenses and increased return on investment. Most virtualization platforms provide redundancy and load balancing, which minimize downtime. Also, unlike traditional computing where you have to go out and buy a physical server, you can spin up a virtual server in a fraction of the time. You can also take server snapshots in case you need to make a server rollback. An entire VM is stored in just a few files, and they can easily be copied or moved as you would any file. Finally, virtualization makes IT tasks much easier to manage and less costly.
With benefits like these, you can see why nearly all companies are using some form of virtualization in their business today.
Before we finish, we need to discuss a possible virtualization attack. Virtual machine escape is one of the security threats an attacker can take advantage of from within a virtual machine. Typically after escaping
out of a guest virtual machine, an exploiter can execute code on the hypervisor or the host operating system. The threat actor can gain access to the primary hypervisor and perform administrative tasks like VM deletion, powering off, resource allocation, and much more. The best way to prevent virtual machine escape is to regularly patch your hypervisor. Keeping your hypervisor current goes a long way in preventing exploits.
That's it for this lesson. In this lesson, you were introduced to virtualization's common roles and functions. We discussed how virtualization works, different virtualization types, the hypervisors you can use, and virtualization benefits. We ended this lesson by discussing virtual machine escape and how you can prevent these attacks.

10.1.2 Load Balancing with Virtualization (Lesson Video)

Transcript:

Virtualization provides many advantages above simply installing an operating system on a physical computer system. One powerful benefit and feature is load balancing. Let's look at how load balancing works with virtual machines, or VMs.

VMs run on top of a hypervisor which is installed on physical hardware called a host. The hypervisor decouples the hardware from the VMs, or workloads.
If we have two or more hosts, we can create a cluster. Clusters usually require shared storage like a SAN where the actual VM files reside and can be managed as a single entity. While workloads are running in memory, they still use real resources â€“ real physical memory, real storage, and really CPUs, and the cluster manages that linking in an effective, optimized way.
For example, if the cluster contains eight host servers with four quad-core CPUs each running at 4GHz and 64GB of memory, the cluster has an aggregate of 512GHz of CPU power and 512GB of memory available for running VMs. Having a cluster provides a number of benefits, including high-availability, load balancing, and high performance. Let's look at load balancing.
A cluster can sense which hosts are busy and offload workloads to a less busy host. It does this by monitoring hardware resources like CPU and RAM on each host of the cluster to determine the best placement for all the workloads. The load is evaluated frequently, and workloads can be adjusted dynamically to reallocate when needed.
This means a VM or workload could move from one host to another in a cluster for better performance. And what's cool is this is seamless to the userâ€”they don't even notice all this is happening on the back end.
This dynamic allocation load balances the workloads across hosts in the cluster based on host resource load and availability. When a host gets busy, workloads will be moved to another host on the fly. That's powerful, and ensures each workload gets the very best performance possible.
Not all your hosts will have the same hardware with CPU and RAM resources. Some hosts will be beefier than others. Some will have newer processors. This means that some hosts can handle more dense workloads than others. The cluster can sense how busy each host is and adjust, or load-balance, the workloads for best performance and to best utilize CPU and memory resources across the cluster.
Within a cluster, we can usually create what's called a resource pool. This helps us allocate CPU and RAM resources to prioritize our workloads.
Some workloads may have applications that are mission critical and require specific resources to always be up and running properly. Other workloads may not be as important, but still need adequate resources. Resource pooling allows us to establish performance boundaries within the cluster, so resources aren't consumed by low-level workloads and keep important workloads from starving for resources.

So, a resource pool works within the cluster, and may span two or more host servers. Let's create Resource Pool A with a certain amount of RAM and CPU shares. After creating the pool, we can then assign or create VMs to run in the pool. We can create as many pools as we like in our cluster, but we must always assign them CPU and memory performance. Here's another pool â€“ Resource Pool B. We'll assign it a certain amount of CPU and RAM, and then we'll assign VMs to it.
In essence, the workloads end up being load balanced, and they are throttled to only use the established resource limits. This allows admins to aggregate computing capacity and delegate it for use rather than focus on individual host servers. And, as a bonus, if one host server goes down, the other servers in the cluster will pick up the workloads and continue on.
You can create a resource pool on an individual host. However, if you have a cluster, resource pooling will provide more resources across the hosts in a cluster, allowing you to better manage the use of those hardware resources, including reservations for CPU and RAM usage. The VMs will be load balanced within the resource pool within the cluster. This provides for rapid elasticity which leverages virtualized server and storage technologies to rapidly meet the rise and fall of user load and service demand.
Hypervisor software that supports resource pooling is downloadable from the internet. You can download an evaluation copy to set up and experiment with load balancing on virtual machines.
That's it for this lesson. Within the context of virtualization, that's how load balancing works. Clustering allows VMs to be load balanced and highly available while providing the best performance possible for each workload. And resource pooling allows us to aggregate hardware resources across multiple hosts ensuring that the workloads get the resources they need without sacrificing the performance of others.

10.1.3 Virtualization Facts

This lesson covers the following topics:

- Virtualization components
- Virtualization advantages and disadvantages
- Virtualization security
- Load balancing

Virtualization Components

Virtualization refers to installing and running multiple operating systems concurrently on a single physical machine. Virtualization typically includes the following components:

Component	Description
Physical machine	A *physical machine* , also known as the host operating system, has the hardware, such as the hard disk drive(s), optical drive, RAM, and motherboard.
Virtual machine	A *virtual machine* , also known as the guest operating system, is a software implementation of a computer. The virtual machine executes programs in the same way a physical machine executes programs. The virtual machine appears to be a self-contained and autonomous system.
Virtual hard disk (VHD)	A *virtual hard disk* (VHD) is a file created within the host operating system and simulates a hard disk for the virtual machine.

Hypervisor	A *hypervisor* is a thin layer of software that resides between the guest operating system and the hardware. A hypervisor allows virtual machines to interact with the hardware without going through the host operating system. There are two types of hypervisors. A Type I hypervisor is often called a native hypervisor or bare-metal hypervisor. A hypervisor in a dedicated appliance is called an embedded hypervisor. A Type I hypervisor is like a thin operating system that directly interfaces with the computer hardware. Examples of Type I hypervisors are: VMware ESX and ESXi Microsoft Hyper-V Linux KVM Citrix Hypervisor Xen Oracle VM A Type 2 hypervisor is known as a hosted hypervisor. It runs as an application on a conventional operating system. While it may be used in a production environment, a type 2 hypervisor is most often used as a development sandbox. Examples of Type II hypervisors are: VMware Workstation and VMware Player Oracle Virtual Box Microsoft Hyper-V built into Windows 8.1 and 10 Parallels Desktop for Mac
Containerization	Containerization is an alternative to using a hypervisor, which enforces resource separation at the operating system level. The OS defines isolated "cells" for each user instance to run in. Each cell or container is allocated CPU and memory resources, but the processes all run through the native OS kernel. These containers may run slightly different OS distributions but cannot run different types of guest OSes (you could not run Windows or Ubuntu in a Red Hat Linux container, for instance). Alternatively, the containers might run separate application processes, in which case the variables and libraries required by the application process are added to the container. One of the best-known container virtualization products is Docker (docker.com). Containerization underpins many cloud services. In particular, it supports microservices and serverless architecture. Containerization is also being widely used to implement corporate workspaces on mobile devices.

Virtualization Advantages and Disadvantages

The advantages of virtualization are described in the following table.

Advantage	Description
Flexibility	Virtual machines can be given network access. Other network devices will consider them to be physical machines. Be aware that virtual machines: Should have the latest service packs and patches, just like physical machines. Should be hardened, just like physical machines. Can be connected to the production network by creating a bridged (external) virtual switch. Because they are self-contained, virtual machines can be easily moved between hypervisor hosts as needed.
Security	To better protect other systems, virtual machines can be used to create honeypots and honeynets to attract attackers so you can analyze attacks on the system.
Testing	Virtual machines can be configured in a lab environment that mirrors a production network. This lab environment can be used to: Test applications before installing them on production systems. Test updates and patches before rolling them out into the production environment. Test security controls to verify that they are working as designed.
Server consolidation	Server consolidation allows you to move multiple physical servers onto a few physical servers with many virtual machines. *Physical-to-virtual migration* (P2V migration) is the process of moving an older operating system off aging hardware and into a virtual machine. Consolidating servers: Requires fewer physical computers. Reduces power consumption. Increases physical server utilization of resources. Increases administrative efficiency. Reduces the number of incompatibility issues.
Isolation	A virtual machine can be isolated from the physical network to allow testing to be performed without impacting the production environment. This is called sandboxing.

	Sandboxed virtual machines offer an environment in which malware can be executed with minimal risk to equipment and software. Sandboxing virtual machines protects them from many kinds of security threats. To allow isolated virtual machines to communicate with each other, create a new virtual switch configured for host-only (internal) networking. Connect the virtual network interfaces in the virtual machines to the virtual switch.
Application virtualization	Applications can be virtualized. A virtual application appears to be local but is really running on a different system. Virtualized browsers can protect the underlying physical operating system from malware installation. Any malware installed from the virtual browser affects only the browser, not the rest of the system. Malware can also use virtualization techniques that make it difficult to detect.

Disadvantages of virtualization include:

Disadvantage	Description
Attacks	An attack on the host machine could compromise all guest machines operating on that host.
Bottleneck	A bottleneck or failure of any hardware component that is shared between multiple guests, such as a failure in a disk subsystem, could affect multiple virtual machines.
Complexity	While administration is centralized, virtualization is a newer technology and requires new skills. Managing virtual servers can add complexity.
Server sprawl	Your configuration is susceptible to server sprawl, a condition that delays patch and security update management due to the number of virtual machines that must be managed.
VM escape	A VM escape is when an attacker with access to a virtual machine breaks out of this isolated environment and gains access to the host system or other VMs running on the same host. Such a vulnerability could allow an attacker to gain control of all virtual machines running on a single physical server, leading to a potentially devastating security breach. A famous example is the "Cloudburst" vulnerability in VMware's virtual machine display function. The Cloudburst vulnerability, officially designated as CVE-2009-1244, was a critical security flaw discovered in 2009 in VMware's ESX Server, a popular enterprise-level virtualization platform. A vulnerability in the virtual machine display function allowed a guest operating system to execute code on the host operating system.

Resource reuse	Virtual machines are frequently created, used, and then deleted in a virtualized environment. If the resources, such as disk space or memory, are not properly sanitized between each use, sensitive data could be leaked between virtual machines. For instance, a new virtual machine may be allocated disk space previously used by another VM. If this disk space is not properly wiped, the new VM could recover sensitive data from the previous VM. Thorough data sanitization practices, ensuring data encryption throughout the lifecycle, and implementing robust encryption key management practices mitigate the risk of resource reuse in cloud infrastructure. Training on cloud provider security features and best practices and segregating resources based on security levels also mitigate risks.
Hypervisor	Attackers exploit hypervisors to gain unauthorized access and compromise the virtual machines (VMs) running on them. Hypervisors typically provide specialized management interfaces so administrators can control and monitor their virtualized environments. These interfaces can become potential attack vectors if insecure. For example, weak authentication, lack of encryption, or vulnerabilities in communication protocols can lead to unauthorized access to the virtualized environment. Like any software, hypervisors have vulnerabilities that must be regularly patched.

Virtualization Security

Security considerations for a virtual machine should be the same as for physical machines. For the host and all guest machines, be sure to:

- Reduce the number of services running.
- Apply patches and updates regularly.
- Install antivirus and other security software.
- Implement backups, operating system snapshots, and other solutions for data protection.

In addition, you should protect against virtual machine escape, an exploit in which malware allows the operating system within a virtual machine to break out and interact directly with the hypervisor. To minimize this vulnerability:

- Apply patches and updates regularly.
- Install only the resources-sharing features that are necessary.
- Install only the software applications that are necessary.

Load Balancing

Load Balancing is a technique that disperses a workload between two or more computers or resources to achieve optimal resource utilization, throughput, or response time. The primary goal of load balancing is to improve performance and create high availability by configuring multiple devices to respond as one. Load balancing can also provide fault tolerance.

If the load balancing mechanism is able to detect when a specific node or member is unavailable, new requests will automatically be distributed to other available members. Load balancing methods with virtualization include the following:

Resource pooling creates shared logical pools of CPU and memory resources from many physical machines within the hypervisor to guarantee a level of resources for specific virtual machines.

Workload balancing distributes a workload (the total requests made by users and applications of a system) across multiple computers or a computer cluster to achieve optimal resource utilization, maximize throughput, minimize response time, and avoid overload.

10.1.4 Use VMWare Player (Demo Video)

Transcript:

In this demo, we'll be working with VMware Workstation Player, which is software that allows the installation of virtual machines, or VMs. This software is similar to commercially available hypervisors, but on a much smaller scale. VMware Workstation Player is designed to be used on your desktop for either personal or business use. Today, we'll just be looking at the standard edition that you'd use in a home lab or for testing.

Let's go ahead and walk through a virtual machine installation. We have several options off to the right. Create a New Virtual Machine will start the wizard to add a virtual machine to our player. Open a Virtual Machine will add a virtual machine that was already created elsewhere or with an open virtual machine format, such as an .ovf file. There's an upgrade option here to get Workstation Pro, which gives you more features than would typically come with VMware's ESXI hypervisor, but this requires a paid license. You can always get help if you're feeling stumped and want to check out more information. We're going to go ahead and create a new VM.
Typically, operating systems have an ISO that's downloadable from their website. We have some ISOs already downloaded, so we're just going to click Browse. We'll select our Win11 ISO file and click Open. From here, we just need to click Next. Quickly make sure that the Guest operating system is set appropriately. In our case, it'll be Microsoft Windows and the version will be Windows 10 and later x64. Click Next.
Here it gives you an option to name the VM and its location. Just to make things easier, I'll change the name to Windows11 and leave the location alone. Click Next. Okay, this is one feature that's sort of unique. We have the ability to store the VM's disk as a single file or break it up into smaller files. It says that it might be easier to move the smaller files, but in our case, we just want to keep it as one. Also, be mindful of how much disk space you have on your workstation and how much you plan to use in the future on this virtual machine. There are usually bare bone requirements for all operating systems. Of course, you may want to add more if there's another purpose to this VM. Let's click Next.
Notice that it didn't give me the option to tweak more VM settings. If you do want to finetune things more, like adding more CPU or memory, tweaking the network, etc., you can customize the hardware here or do it after the fact by right-clicking on the VM and going to Settings. Click Finish.
Now we have a newly created VM ready to boot. Let's go over the Settings that we have. Some of this is self-explanatory, like adding or removing Memory, Processors, or even Hard Disk space. The Network Adapter is where it gets interesting. There are many types of network connections to choose from. Bridged connects directly to the physical network card, NAT shares the host's IP address, Host-only puts the VM in an isolated private network, Custom drops it in a virtual network, and LAN segment does something similar. NAT may be your best choice if your VM just needs to reach the internet and isn't going to be used in conjunction with other VMs. If you want to network several VMs together, you can use a custom virtual network or LAN segment.
For example, if I wanted to create a firewall VM that all my VMs go through first before they hit the internet, I might have two network adapters in here. One of them would be the NAT, the internet source, while the secondary one would be the LAN or a custom virtual network of my choosing. Then all the other VMs would use the virtual network and not the NAT connection.
In our demo, we're just going to leave it on NAT and click OK.
Now it's time to power this on. Clicking Play virtual machine makes it come alive. And just like that, we're booting the Windows 11 ISO to start the installation process. Keep in mind that you have to leave the player open to run these VMs. These aren't meant to run what they call "headless" and in the background with VMware Workstation player. Once this application is closed out, your VMs close out as well.
That's it for this demo on virtual machines. In this demo, we discovered VMware Workstation Player. We also showed you how to install a VM and tweak its settings.

10.1.5 Use Hyper-V (Demo Video)

Transcript:

Hyper-V is virtualization software created by Microsoft in 2016 that lets you run other software like it's on a physical computer. We call this a virtual machine, or VM. With a VM, you're able to have many different operating systems installed on one physical system.

Today, we're going to look at how to enable Hyper-V on a desktop. In the Start menu, look for the features keyword, and it'll direct you to the section to add or remove features. Alternately, you could go to Control Panel > Programs > Turn Windows features on or off. This is the area that controls extra features that come with Windows, ones that might not be enabled by default. Also, before we go on, it's important to know that you won't be able to enable Hyper-V unless you have the Pro version of Windows.
Now, after clicking OK, it'll process your request when it's done and require a reboot. We're going to do that now, so I'll pause the recording.
Okay, our reboot is complete, and we're ready to launch Hyper-V. To do so, we go to Search and type hyper-v. This brings us the Hyper-V Manager. Eventually, when you have VMs, they'll be populated over here. This manager allows you to control all the local Hyper-V instances along with remote ones.
We're only worried about our local one, so we're going to right-click here and select Virtual Switch Manager. Here's where we manager the virtual switches that'll be used for the VMs. It's a good idea to configure these first so you know how your network is going to be set up. And there are three options to select from here. External binds to the physical network adapter. This would give a VM access to the internet and the physical network that your PC is connected to. The Internal switch is similar except that it doesn't allow direct access to the internet. This would be a good option if you had several VMs that needed to talk to each other without access to a physical network. Private is completely isolated. Some use cases for this would be restoring a VM for testing purposes that you don't want to communicate with anything.
We're going to do something simple and select Internal. Let's give it a name of Internal as well. We'd have the ability to select the Ethernet controller or Wi-Fi adapter if we'd used the external network switch. If there were other network adapters available, they'd be listed here, too. And if you were running VLANs, you could select this and tag the network with a certain VLAN ID. Click Apply when you're done creating your switch.
One thing to notice here is the Default Switch. This switch does use the Internal network setting, but the part at the bottom makes it different from the internal network we just created. This has NAT, or Network Address Translation, set up to give your VMs access to the computer's physical network. If the NAT weren't on, you wouldn't have access to the physical network. This default is set this way to make it easy for users to start right out of the box. Anyway, click OK.
Now we're ready to create our first VM. Right-click on the host and select Quick Create. In here, we select the ISO of our choosing from some default options, or we could just upload our own from a local source. I happen to have one in my Downloads folder, so I'm going to go search and grab my Windows ISO. After selecting Open, we're able to go through and create our virtual machine.
Before booting, we need to check out some settings first. They make it handy by giving us the ability to launch the settings from here. In here are all the settings related to the VM we just created. We're able to tweak quite a few aspects, like Memory, Processor, Hard Drive, and more. Let's adjust some of these. Our memory is a little low, for default specs of Windows, we can up it to 4096. It does have the ability to dynamically change as well. Under Processor, it's set to 8. Let's adjust it to 2. Under Network Adapter, we need to configure this VM to use the network we created. For our case, we need to use the isolated network. However, it's possible to create a firewall VM with two network adapters, one being connected to the physical network and the second one to the internal network we just created. Essentially, that'd give you total control of what comes in and out of your Hyper-V host VM. Lastly, let's give this a name. This could be a convention or something of your choosing. Apply and click OK.
Connect allows us to start the process to power on the VM. This is essentially the VM's console, just like you'd see from a computer booting up from a monitor. Click Start. And just like that, we've started the process to install Windows.
And that's it for this demo. In this demo, we went over how to install Hyper-V. We also configured a new virtual switch and created a VM.

10.1.6 Create Virtual Machines (Simulation)

Scenario

You have installed Hyper-V on ITAdmin. You're experimenting with creating virtual machines.

In this lab, your task is to create two virtual machines named VM1 and VM2. Use the following settings as specified for each machine:

VM1:

- Virtual machine name: **VM1**
- Virtual machine location: **D:\HYPERV**
- Generation: **Generation 1**
- Startup memory: **1024 MB** (do not use dynamic memory)
- Networking connection: **External**
- Virtual hard disk name: **VM1.vhdx**
- Virtual hard disk location: **D:\HYPERV\Virtual Hard Disks**
- Virtual hard disk size: **50 GB**
- Operating system will be installed later

VM2:

- Virtual machine name: **VM2**
- Virtual machine location: **D:\HYPERV**
- Generation: **Generation 1**
- Startup memory: **2048 MB** (use dynamic memory)
- Networking connection: **Internal**
- Virtual hard disk name: **VM2.vhdx**
- Virtual hard disk location: **D:\HYPERV\Virtual Hard Disks**
- Virtual hard disk size: **250 GB**
- Operating system will be installed later
- Minimum RAM: **512 MB**
- Maximum RAM: **4096 MB**

Explanation

While completing this lab, use the following virtual machine (VM) specifications:

VM1:

Virtual machine name: **VM1**

Virtual machine location: **D:\HYPERV**

Generation: **Generation 1**

Startup memory: **1024 MB** (do not use dynamic memory)

Networking connection: **External**

Virtual hard disk name: **VM1.vhdx**

Virtual hard disk location: **D:\HYPERV\Virtual Hard Disks**

Virtual hard disk size: **50 GB**

Operating system will be installed later

VM2:

Virtual machine name: **VM2**

Virtual machine location: **D:\HYPERV**

Generation: **Generation 1**

Startup memory: **2048 MB** (use dynamic memory)

Networking connection: **Internal**

Virtual hard disk name: **VM2.vhdx**

Virtual hard disk location: **D:\HYPERV\Virtual Hard Disks**

Virtual hard disk size: **250 GB**

Operating system will be installed later

Minimum RAM: **512 MB**

Maximum RAM: **4096 MB**

Complete this lab as follows:

Access the Hyper-V Manager.

Select **Start** .

Expand **Windows Administrative Tools** and then select **Hyper-V Manager** .

Create virtual machines on ITAdmin.

Use all default settings unless directed otherwise.

Right-click **ITADMIN** and then select **New** > **Virtual Machine** .

From the Before You Begin dialog, select **Next** .

In the Name field, enter ***VM_ name*** and then select **Next** .

Make sure **Generation 1** is selected, and then select **Next** .

In the Startup memory field, enter ***size*** .

Set the **Use Dynamic Memory for this virtual machine** appropriately, and select **Next** .

Use the Connection drop-down menu to select ***connection_type*** and then select **Next** .

In the Size field, enter ***disk_size*** and then select **Next** .

Make sure **Install an operating system later** is selected and then select **Next** .

Review your configuration and then select **Finish** to create the virtual machine.

Repeat step 2 to create the second virtual machine.

Adjust virtual machine memory for VM2.

From the Hyper-V Manager, under Virtual Machines, right-click **VM2** and select **Settings** .

From the left pane, select **Memory** .

In the Minimum RAM field, enter **512** .

In the Maximum RAM field, enter **4096** .

Select **OK** .

10.1.7 Use Windows Sandbox (Demo Video)

Transcript:

As an IT administrator, you'll often be asked to install new software on the Windows systems running in your office. Before installing any new software you're unfamiliar with, it's always important to first test the software to see how it will function. This can be done using Hyper -V virtual machines, but that requires the extra steps of installing the operating system and getting things ready. It also requires additional space on your disk to store the virtual machine.

To make testing software easier, Microsoft offers a lightweight desktop environment known as Windows Sandbox, where you can safely run applications in an isolated environment. The beauty of using Windows Sandbox is that once Windows

Sandbox is closed, all the software and files that were added when the application was installed are deleted. This means you get a brand-new instance of the sandbox every time you open the application.
To use Windows Sandbox, you must add this feature to your system.
To do this, first, open the Settings app. Next, select Apps. Now, from the right, select Optional features. From this page, scroll down and select More Windows features. It's from here that you can add or remove features.
From this dialog, scroll down and select Windows Sandbox and click OK. If the Windows Sandbox option is unavailable, your computer doesn't meet the requirements to run Windows Sandbox. As you can see, after the feature has been installed, you'll be required to restart your system, so I'll click Restart now.
With the computer restarted, you can now use Windows Sandbox to install and test a new application. To do this, let's click on Start and select All apps. I'll then go down and run Windows Sandbox. Notice that the Windows Sandbox window is opened, which looks like another Windows machine.
For this demo, I'm going to install the Audacity program. To save time, I've already downloaded the install file for this program and saved it to my Downloads folder on the host computer. Let's copy and paste this to the desktop of our sandbox. Now, let's maximize the sandbox window for easier viewing.
From this point, you simply install the application as you would in a normal Windows environment. So, let's double-click on the install file and follow the remaining prompts to install Audacity. Once the application has been installed, I can test it to verify it didn't have any ill effects on my system and functioned the way I wanted it to.
When you're done testing your application, all you need to do is close Windows Sandbox. Notice that when you do, you're warned that all your changes will be permanently lost. That's fine, so I'll click OK.
Just to verify that everything was deleted, let's open Windows Sandbox again. This time let's use the Search feature to find and open this tool. Notice that the installation file for Audacity is gone, as well as the shortcut to run the program. And when I access All apps, you can see that Audacity isn't available.
That's it for this demonstration. In this demo, we showed you how to install the Windows Sandbox feature. We then showed you how to use Windows Sandbox to install and test applications.

10.1.8 Create Containers (Demo Video)

Transcript:

Were going to give you an overview on how you can create a container. If your not familiar with a container it is similar to a virtual machine however instead of having the overhead of several operating systems for each software you can just run the software from an image a container engine. Today were going to be using a container engine called docker desktop. This is widely used by developers and for the use of learning containers. We already have this installed so lets go ahead and launch it from the start menu.

Typically to start you will have an image in which you would build a container from. If you were a developer you would of course make your own image with the required software in it to run as a container. If you don't have an image and want to start from a basic one you could go up to the search bar and type apache for example. If you don't know what apache is it is a web server. In order to grab an image we need to pull it. Once we click pull it will download the image and put it in our Image repository. If there are any updates to an image you would have to pull again to obtain your update.
Now that we have our image downloaded we can now create a container from the image. By clicking on the run option from the image it starts the process to create the container. It does give some optional settings like changing the ports or the volumes it may use. Were going to assign it a random port so we will just type zero here and click run. To check our running containers we can venture to the other menu called containers. All running containers will be displayed here. You can see we have one running which is our web server. Locally on the container it is using port 80 however its redirecting it to port "" . clicking the port reference will allow us to launch the web page from our browser. Since we actually see a page and its presenting a text means our container is working properly. Not all containers will have a web page like this one, for example if its a database container you will have connecting ports available but no website to test.
Along with the gui you can still utilize command line tools to manage your docker images and containers. Were just going to check the status of our running container by launching our terminal. Once launched we can type the command "docker ps" this will show us all our running containers. Once we have the container we want we can run a command like "docker stop c764f54a8429" to stop a container. You can see from the docker ps the container isnt running anymore. Each container has a unique container ID. This ID has to be used when using these commands to manage a container. Just like we can run "docker start c764f54a8429" to start the container we just stopped. Running a docker ps will show the container is running again.

That is it for this demo. In this demo we showed you how to create a container on docker desktop. We also showed you docker containers can be managed by command line tools.

10.1.9 Secure Containers (Demo Video)

Transcript:

In this demo, we will explore various ways to enhance the security of your containers.

In the world of IT, we are always vigilant, searching for vulnerabilities that hackers might exploit to compromise our systems. This concern isn't limited to just bare-bone servers and virtual machines; it extends to containers as well. Containers, such as this Apache web server, are streamlined versions of Linux with only the essential software required to run Apache. When we inspect the image we have in our image store, we can see that it has 32 vulnerabilities with the current container we are running. The top one is marked as "high" priority. The medium and low vulnerabilities are less concerning. If you wish to learn more about the Common Vulnerabilities and Exposures (CVE) or Debian Security Advisories (DSA) associated with these vulnerabilities, you can access that information through the provided links. You can also observe the breakdown of the Docker image, which consists of multiple layers, each possibly having vulnerabilities.
Now, if you examine the image closely, you'll find it comprises two parts: a base Debian image and an httpd image. Keep this in mind as we explore potential fixes. Notably, the httpd image doesn't have any updates, whereas the base image does. While you can review the recommended base image, remember that the image we downloaded can only be modified by its owner. As we are not the owner, our best course of action is to either pull down a new image or create our own image to address this issue. Let's start by attempting to pull a new image using the option to "pull a new image." However, as you can see, when we exit and re-enter, there are no changes to the vulnerabilities.
One potential solution is to update the running container to patch vulnerabilities. Keep in mind that if this container were deleted and rebuilt from the image, the changes we make inside the container will be lost. The primary aim is to address vulnerabilities while waiting for an updated image. As we have one running container from our Apache container image, let's proceed. Within the exec window, we can use the command line to access the Linux system inside the container. Running "apt update" will download the latest packages from the repository, similar to a regular Linux server. If you are wondering if the high vulnerability fix is included in these packages, you can check by running "apt list --upgradable" to see if it's on the list. It appears it isn't, but there are other fixes we can apply. Running "apt upgrade" will begin the process to upgrade the packages. Let's proceed and confirm. We'll fast forward a bit.
Now our container is patched. It's a good practice to restart the container after applying patches. As mentioned earlier, this is a workaround until the image is updated with the latest patches.
Each running container will receive an IP address. The network configuration may vary depending on where your containers are hosted. In our specific setting under "resources" and "network," you can observe a Docker subnet of 192.168.65.0/24, which is the default setting. However, you may need to adjust this based on your requirements. The core concept behind network segmentation is to grant designated servers and users access only to specific network resources. For example, if our accounting department uses an Apache website container, while the marketing department does not, we can block the marketing department from using it. Adding more hurdles within the network may make it more complex, but it also reduces the attack surface for potential hackers.
Simple adjustments, such as using alternate ports, can enhance security. If you examine our currently running container, you'll see it might be using port 80, but it's being redirected to port number 32771. The idea behind using alternate ports is that hackers often scan for specific port numbers. Typically, these are the default port numbers like 80 or 443 for HTTP and HTTPS. While you can't change port 443 for a regular website on the internet, you can do so on your private network. For instance, if we were to set up another Apache website, we could run it on a different port. In the optional settings, you can either allow it to select a random port or choose one yourself. Let's select "8080" as an alternate port to port 80. Now, if we try to launch the web page, you can see it works on port 8080. It's worth noting that this container now requires the patches applied to the previous container.
There are various methods to enhance the security of your containers, and these are just a few strategies to consider when securing your network. That concludes this demonstration. In this demo, we discussed how to identify vulnerabilities within a container image. Additionally, we explored the concepts of network segmentation and the use of alternate ports for added security.

10.1.10 Practice Questions (Section Quiz)

q_virt_browser_01_secp8

You have a development machine that contains sensitive information relative to your business. You are concerned that spyware and malware might be installed while users browse websites, which could compromise your system or pose a confidentiality risk.

Which of the following actions would BEST protect your system?

Answers:

***Run the browser within a virtual environment.**

Configure the browser to block all cookies and pop-ups.

Run the browser in protected mode.

Change the security level for the internet zone to High.

Explanation:

To best protect your system, run the browser in a virtual environment. Virtualization creates an environment that is logically separated from the main system. Any problems that occur within the virtual environment are contained within that environment and do not affect the rest of the system.

While configuring the browser to block all cookies and pop-ups can somewhat help, in this scenario, you need a more robust solution, such as running the browser within a virtual environment.

While running the browser in a protected mode limits how much access malware, spyware, or other potentially harmful code has to your system, it does not work as well as running the browser within a virtual environment.

Once again, setting the internet security zone to High can provide some measure of security; in this scenario, the best solution is to run the browser within a virtual environment.

q_virt_browser_02_secp8

Which of the following is an advantage of a virtual browser?

Answers:

***Protects the host operating system from malicious downloads**

Prevents adware and spyware that monitor your internet activity

Prevents phishing and drive-by downloads

Filters internet content based on ratings

Explanation:

A virtual browser operates within a security sandbox that keeps activities within the browser from affecting the rest of the system. For example, malware downloaded by the virtual browser is limited to the security sandbox and cannot harm the operating system.

The virtual browser does not prevent adware, spyware, or phishing. These threats are still possible within the virtual browser. However, if malware is installed within the virtual session, the malware cannot harm the rest of the system, and the virtual browser can be easily restored to remove the malicious software.

q_virt_containerization_01_secp8

To address the escalating operational costs and complexities stemming from multiple standalone applications, an organization plans to restructure its software deployment process.

They want to minimize overhead, increase flexibility in development environments, and enhance the efficient use of system resources.

What approach would be the MOST effective?

Answers:

***Containerization**

Virtualization

Microservices

Hybrid cloud infrastructure

Explanation:

Containerization encapsulates applications and their dependencies, which provides the flexibility to run them across different environments. It also allows for better resource utilization, as each container only holds the application and its related binaries/libraries, effectively reducing overhead.

Virtualization can provide some cost savings and flexibility but generally consumes more resources than containerization, as each virtual machine requires its own operating system.

Microservices bring flexibility and go in a container, but they do not directly lead to better resource utilization, as they do not impact how applications use system resources.

Hybrid cloud infrastructure provides scalability and potential cost savings but does not enhance the efficient use of current system resources.

q_virt_containerization_02_secp8

A tech company wants to increase its security measures by isolating its various development, testing, and production environments.

The company wants to ensure that these environments are reproducible and managing these dependencies consistently.

Which approach would be MOST beneficial in meeting these requirements?

Answers:

***Containerization**

Virtualization

Software-defined networking (SDN)

Industrial control systems (ICS)/supervisory control and data acquisition (SCADA)

Explanation:

Containerization allows the isolation of environments while also providing reproducibility and efficient dependency management. Each container includes the application and all its dependencies, ensuring that it will run consistently across different environments.

Virtualization does not inherently provide the level of isolation between applications or manage dependencies as effectively as containerization.

Software-defined networking (SDN) can be useful for managing network traffic and isolating parts of the network, but it does not address the reproducibility and dependency management concerns mentioned in the scenario.

Industrial control systems (ICS)/supervisory control and data acquisition (SCADA) systems control industrial processes and collect data from them, respectively. They are not particularly relevant for creating isolated and reproducible software development environments.

q_virt_escape_01_secp8

Which of the following is an exploit in which malware allows the virtual OS to interact directly with the hypervisor?

Answers:

***Escape**

Jump

Bottleneck

Load balancing

Explanation:

Virtual machine escape is an exploit in which malware allows the operating system within a virtual machine to break out and interact directly with the hypervisor.

Jump is not a type of VM exploit.

Load balancing is a technique that disperses a workload between two or more computers or resources to achieve optimal resource utilization, throughput, or response time.

A bottleneck is an area (software, hardware component, etc.) where all traffic slows down.

q_virt_escape_02_secp8

Evaluating the security risks tied to a company's virtualized environment, a network administrator relies on multiple virtual machines (VMs) for service distribution throughout the infrastructure.

The administrator's primary concern is a specific risk: an application compromised within a VM might interact with the host system and potentially propagate harmful activities.

What strategy should the network administrator employ to mitigate this risk and guarantee the individual VMs' integrity and isolation in the company's virtualized environment?

Answers:

***Mitigating virtual machine escape**

Implementing network segmentation

Establishing firewall rules

Enforcing user access controls

Explanation:

Virtual machine escape is a critical security issue in a virtualized environment, where an application, process, or user within a virtual machine can bypass the virtual machine's barriers and interact directly with the host system.

Network segmentation enhances security but does not directly address a virtual machine escape scenario.

Firewalls mainly govern inbound and outbound network traffic. They do not prevent a virtual machine escape situation.

Enforcing user access controls is primarily about controlling who has access to specific resources within a system or network. It does not directly secure a VM from the possibility of breaking its isolation and interacting with the host system.

q_virt_hyper_secp8

Which of the following devices is computer software, firmware, or hardware that creates and runs virtual machines?

Answers:

Virtual switch

Virtual router

Virtual firewall

***Hypervisor**

Explanation:

A hypervisor is computer software, firmware, or hardware that creates and runs virtual machines. A computer on which a hypervisor runs one or more virtual machines is called a host machine. Each virtual machine is called a guest machine. The hypervisor provides the guest operating systems with a virtual operating platform and manages the execution of the guest operating systems.

Virtual switches, routers, and firewalls are part of the virtual environment that enable transmission of network data but have nothing to do with creating and running the virtual machines.

q_virt_load_balance_secp8

Which of the following is a technique that disperses a workload between two or more computers or resources to achieve optimal resource utilization, throughput, or response time?

Answers:

Virtualization

Hypervisor

***Load balancing**

Bottleneck

Explanation:

Load balancing is a technique that disperses a workload between two or more computers or resources to achieve optimal resource utilization, throughput, or response time. The primary goal of load balancing is to improve performance and create high availability by configuring multiple devices to respond as one.

A hypervisor is a thin layer of software that resides between the guest operating system and the hardware.

Virtualization refers to installing and running multiple operating systems concurrently on a single physical machine.

A bottleneck is an area (software, hardware component, etc.) where all traffic slows down.

q_virt_sandbox_secp8

What is isolating a virtual machine from the physical network to allow testing to be performed without impacting the production environment called?

Answers:

Resource pooling

***Sandboxing**

Testing

Workload balancing

Explanation:

Isolating a virtual machine from the physical network to allow testing to be performed without impacting the production environment is known as sandboxing.

Resource pooling creates shared logical pools of CPU and memory resources from many physical machines within the hypervisor. This guarantees a level of resources for specific virtual machines.

Virtual machines can be configured in a lab environment that mirrors a production network to provide a testing environment.

Workload balancing distributes a workload (the total requests made by users and applications of a system) across multiple computers or a computer cluster to achieve optimal resource utilization, maximum throughput, minimal response time, and less overload.

q_virt_server_secp8

Which of the following is a disadvantage of server virtualization?

Answers:

***A compromised host system might affect multiple servers.**

It increases hardware costs.

A compromised guest system might affect multiple servers.

Systems are isolated from each other and cannot interact with other systems.

Explanation:

Virtualization allows a single physical machine (known as the host operating system) to run multiple virtual machines (known as guest operating systems). The virtual machines appear to be self-contained and autonomous systems. Disadvantages of virtualization include:

An attack on the host machine could compromise all guest machines operating on that host.

A bottleneck or failure of any hardware component that is shared between multiple guests, such as a failure in a disk subsystem, could affect multiple virtual machines.

While administration is centralized, virtualization is a newer technology and requires new skills, so managing virtual servers could add complexity.

A compromise of a guest system is typically limited to that system only because each virtual machine is kept partitioned from other guest machines. System isolation, if configured, is an advantage of virtualization. Isolation is typically used for testing purposes and prevents unreliable applications from interfering with other systems. Virtual systems do not need to be isolated. They can be configured to have full network access to other virtual machines or other network devices.

An advantage of virtualization is reduced hardware costs.

q_virt_type2_secp8

Which type of hypervisor runs as an application on the host machine?

Answers:

Type 1

***Type 2**

Type 3

Type 4

Explanation:

A Type 2 hypervisor is known as a hosted hypervisor. It runs as an application on a conventional operating system.

A Type 1 hypervisor is like a thin operating system that directly interfaces with the computer hardware.

There are no Type 3 or Type 4 hypervisors.

q_virt_virtualize_secp8

Which of the following are advantages of virtualization? (Select two.)

Answers:

***Centralized administration**

***Easy migration of systems to different hardware**

Redundancy of hardware components for fault tolerance

Reduced utilization of hardware resources

Improved host-based attack detection

Explanation:

Virtualization allows a single physical machine (known as the host operating system) to run multiple virtual machines (known as guest operating systems). The virtual machines appear to be self-contained and autonomous systems. Advantages of virtualization include:

Server consolidation

The ability to migrate systems between different hardware

Centralized management of multiple systems

Increase utilization of hardware resources

Isolation of systems and applications

Disadvantages of virtualization include:

A compromise in the host system could affect multiple guest systems.

A failure in a shared hardware resource could affect multiple systems.

q_virt_workload_secp8

Which load balancing method distributes a workload across multiple computers?

Answers:

Resource pooling

Virtualization

Bottleneck

***Workload balancing**

Explanation:

Workload balancing distributes a workload (the total requests made by users and applications of a system) across multiple computers or a computer cluster to achieve optimal resource utilization, maximum throughput, minimal response time, and less overload.

Resource pooling creates shared logical pools of CPU and memory resources from many physical machines within the hypervisor. This guarantees a level of resources for specific virtual machines.

Virtualization refers to installing and running multiple operating systems concurrently on a single physical machine.

A bottleneck is an area (software, hardware component, etc.) where all traffic slows down.

10.2 Virtual Networking

As you study this section, answer the following questions:

How does a virtual network differ from a physical network?

What is a Virtual Private Network (VPN)?

What is a virtual machine?

What terms are associated with virtualization and what do they mean?

What is the Dynamic Host Configuration Protocol (DHCP)?

How can physical devices become virtual ones?

Who are some of the network virtualization service providers?

In this section, you will learn to:

Configure virtual network devices.

Create virtual switches.

Key terms for this section include the following:

Term	Definition

Virtual network	A computer network consisting of virtual and physical devices.
Virtual local area network (VLAN)	A virtual LAN running on top of a physical LAN.
Virtual private network (VPN)	A secure tunnel to another network that connects multiple remote end-points.
Virtual machine (VM)	A virtual computer that functions like a physical computer.
Virtual switch (vSwitch)	Software that facilitates the communication between virtual machines by checking data packets before moving them to a destination.
Virtual router (vRouter)	Software that replicates the functionality of a physical router.
Virtual firewall appliance (vFA)	Software that functions as a network firewall device. A virtual firewall appliance provides packet filtering and monitoring functions.
Virtual machine monitor (VMM)/hypervisor	Software, firmware, or hardware that creates and runs virtual machines.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
TestOut Security Pro	3.3 Implement virtualization 3.3.1 Create virtual machines 3.3.2 Create virtual switches
CompTIA Security+ SY0-701	3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts Network infrastructure Virtualization 4.1 Given a scenario, apply common security techniques to computing resources.

	Sandboxing

10.2.1 Virtual Networking Overview (Lesson Video)

Transcript:

One of the benefits of virtualization is the fact that the network environment can be virtualized, as well as the hardware environment. Each virtual machine on a hypervisor can be assigned a virtual network adapter. The virtual network adapter can be connected to either a physical network segment or to a virtual network segment. A virtual network segment has all the components that you would find on a physical network segment. You have the virtual network adapters, you have virtual network switches, and so on.

Let's take a look at how a virtual network works. Over here we have a typical physical network switch; we have traditional user desktops all interconnected using the switch and standard UTP cable, but notice over here that we also have a hypervisor host. This hypervisor host is also connected to the physical network switch with a UTP cable just like any other physical host would be. However, within the hypervisor we have four virtual machines running. One option for configuring virtual networking for these virtual machines is to take their virtual network adapters and bridge them logically--not with actual physical cables--but logically to the physical network interface installed in the hypervisor host, which of course is connected to the physical switch.

By doing this, each of these virtual machines then appears on the physical network as if they were a physical host, just like the systems over here are. The virtual adapter in each one of these virtual machines has their own MAC address and their own IP address. Therefore, they appear to be just a regular host on the physical network. This isn't the only option you have when networking virtual machines. In this example, we've created a virtual switch within the hypervisor. This is not a physical switch with real ports; instead, it's a switch that's running as software in the RAM of the hypervisor itself.

You can actually connect each one of these virtual network adapters and each one of these virtual machines to this virtual switch. We've depicted it here with what appears to be drop cables, but they're not really drop cables they're just logical electrical connections using the hardware, the hypervisor itself, to connect the virtual network adapters to this virtual switch. By doing this, we've created a virtual network segment.

Notice that this virtual switch is not connected in any way to the physical interface and the hypervisor at this time. Therefore, each one of these virtual machines can see each other on the virtual network through the virtual switch, but they cannot see any of these hosts out here on the physical network. This is sometimes called a sandbox environment. If you wanted to, you could actually connect the hypervisor itself to this virtual switch so the hypervisor can interact with these virtual machines on the virtual network. But it still keeps these virtual machines themselves isolated from the physical network and this can be a very valuable configuration, especially if you're in a testing environment.

For example, suppose you're about to roll out a new patch to all of your physical servers. You could set up virtual servers connected to an isolated virtual switch within the hypervisor and then test that update to see if it's going to break anything before you actually roll it out into your production environment. You can even create a router within your hypervisor.

In this case, we've set up a net router that connects our virtual network segment to the physical switch through the physical interface in the hypervisor. In this scenario, we've essentially created a virtual network segment that goes to the NAT router and then out on to your physical network segment. In this configuration, all of these internal virtual hosts are able to contact these physical hosts out here. However, because we're dealing with a NAT router, we can't initiate connections in the other direction of course, but you can go out in this direction. These hosts would be able to get out on the internet, for example, and download patches and updates.

There are a variety of different ways in which virtualization could be implemented. For example, you could implement virtualize servers. However, you could also virtualize desktops, using the virtual desktop interface, or VDI. There are actually many ways to do this. For example, you could create multiple virtual desktops on the same local workstation host. This is very useful in a situation where you're testing an application on multiple platforms to make sure that it runs properly. Another strategy would be to implement multiple desktops on one physical server, and then allow all of your end users to access those virtual desktops remotely.

Essentially, all of your user desktops are provided as virtual machines from a limited number of hypervisor hosts. This strategy could save you a lot of money in your desktop budget. You simply purchase a few high-end servers that will host the hypervisor and as desktop virtual machines. The end users on the other hand will require only very low-end workstations. In fact, they don't even need a hard drive if you have a basic operating system in the firmware of the system. These low-end workstations connect remotely to the hypervisor server and then run the desktop. You can even use virtualization to provide offsite virtualized network components.

For example, you could use virtualization to move your entire data center offsite. Instead of managing it onsite, it's taken care of by a vendor whose physical facility might be miles away from your physical location. In this scenario, the vendor manages your hardware and your software to provide the virtual network that's accessed by your end users. This can be very useful because it only requires very minimal hardware to be maintained at your physical site.

That's it for this lesson. It's important that you're familiar with how virtualization works. Almost all organizations are moving in that direction because of the cost savings associated with virtualization. In this lesson, we talked about how virtual bridging works. We talked about creating a sandbox with virtual networking. We talked about using a NAT router with virtual networking, and then we talked about virtualizing the network infrastructure.

10.2.2 Virtual Network Devices (Lesson Video)

Transcript:

Let's talk a little bit about virtual networks. A virtual network is a computer network consisting of virtual and physical devices. Virtual devices save organizations money. By using less physical storage space, a company is able to have at least twice as many devices in a network because they pay for very little space in a data center.

One form of network virtualization is protocol-based. You should already be familiar with this type of virtualization. VLANs and VPNs are two examples of protocol-based network virtualization.

Remember, with a VLAN, the network devices aren't physically segmented. The only thing that segments these devices is software defining how communications are routed by looking at the VLAN IDs of packets. The same is true with a VPN. There's no dedicated, physical connection between two devices using a VPN. It's a virtualized dedicated connection.

Now, let's go over some virtual networking devices and how they can be used to create a more secure network design.

The first network device we'll look at is a virtual switch, or vSwitch. A vSwitch is a software application that facilitates the communication between VMs by checking data packets before moving them to a destination. vSwitches are often integrated with virtual machine software. Sometimes, they're even part of a server's firmware.

The nice thing about a vSwitch is it's much easier to implement and manage than a traditional switch. In addition, a vSwitch can actually ensure the security integrity of virtual hosts, thereby creating a more secure network. For example, a vSwitch could make sure that a VM meets certain security criteria before it is allowed to communicate on the virtual network. If it fails the security check, its communications will be blocked.

Some of the most common vSwitch platforms are Open vSwitch (OVS), VMware virtual switch, and the Cisco Nexus 1000v. All three can function within a software-defined network as an SDN controller, allowing a much more dynamic network environment.

A virtual router, or vRouter, is a software function that replicates a physical router.

The nice thing about a virtual router is that it doesn't need to rely on the IP routing functionality used by physical routers. This means you can move routing functions around a network freely, creating a more dynamic network environment.

In addition, when you use a virtual router, you are free from a specific vendor ecosystem. This means you aren't locked in to proprietary applications or protocols and can more customize your networking environment. Virtual routers even work well with SDN infrastructure.

Note that, while virtual networking devices can be very flexible and offer a lot of benefits, they still aren't a replacement for physical networking devices.

Virtual networking devices use shared hardware resources, making them a poor choice for resource-intensive tasks, such as encrypting and decrypting information. Load balancing can also become an issue as the resources used to route, switch, and load-balance communication are shared among the devices.

Another drawback is all of these components rely on software applications and are susceptible to things like VM escape. If your entire network is virtualized, there is no physical boundary between certain systems. With physically segmented systems, it is impossible for an attacker to leap between segments without physical access. With virtual segmentation, an attacker only needs to know of an exploit that allows the leap.

That's it for this lesson. In this lesson, we looked at virtual networking devices. We looked at protocol-based virtualization, virtual switches, and virtual routers. We looked at how these virtual devices can benefit a networking environment. And we finished by looking at some of the drawbacks of virtual networking devices.

10.2.3 Configuring Virtual Network Devices (Demo Video)

Transcript:

In this demonstration, we're going to take a look at how to manage virtual devices. There are two types of virtual devices that we can easily manage from here.

One of them would be virtual switches, and I'm using the server version of Hyper-V, which is running on a Windows Server 2022. It's essentially the same as the client version, but all virtualization programs are going to have some type of virtual switch management. In Hyper-V, we're going to access the Virtual Switch Manager. The virtual switch should be created before you create your virtual machines. Now, in Hyper-V, we have different types of virtual switches. For example, I can create a private switch, and I'll just click 'Create Virtual Switch.' The private switch allows the virtual machines to communicate with each other, and that's it. If I wanted to establish an internal network, they could communicate with other virtual machines, interact among themselves and with the host, but they can't access the external network.
Alternatively, I could set up an external network where they can actually use the host's network card directly. You can see there's a check mark here for 'Allow management operating system to share this network adapter.' This means I'm using the same network adapter for both the virtual machines and the host. In a real server environment, it would be best practice to install a couple of network cards, allowing the host to use one network card and the virtual machines to use the other network card.
I can also enable VLANs on my virtual switches if I'm using VLANs. I've created a couple of private switches here, 'private' and 'private 2.' I also have an external switch called 'Internet.' I have plenty to work with. After setting up your virtual switches, the next step is to connect the virtual network cards within the virtual machines to the virtual switch. We're going to examine the settings in this test VM that I have here to see what happens.
I already have a synthetic network adapter installed in this machine, and it's connected to the private network. Again, if I'm using VLANs, I can enable VLAN identification. Depending on your virtualization system, you may have other additional features.
For instance, I can enable bandwidth management to prevent this virtual machine from monopolizing the network card's bandwidth. There are also additional features available when expanding the network card settings. For example, I can configure IPsec offloading, allowing the network card to handle some of the IPsec work when encryption using IPsec is in use. I can specify the details of how it should be handled. Furthermore, there are advanced features where I can customize the MAC address or enable MAC spoofing, which is required for supporting network load balancing. I also have DHCP guard to prevent this virtual machine from acting as a rogue DHCP server and router guard to stop it from becoming a rogue router. Additionally, I can designate it as a protected network, meaning that if its network is disconnected and this machine is part of a high availability solution, it would fail over to the other node in that cluster. Port mirroring allows me to send a copy of network traffic to another machine, which can be useful for monitoring purposes. For instance, if I'm using a product like Network Monitor or Wireshark. I can also implement NIC Teaming, allowing me to use multiple adapters in the guest operating system and link them together for either increased bandwidth or fault tolerance.
In this demonstration, we examined the various options for managing virtual devices.

10.2.4 Virtualization Implementation Facts

This lesson covers the following topics:

- Virtual networking
- Networking virtualization providers

Virtual Networking

A virtual network is made up of one or more virtual machines configured to access local or external network resources. Important facts about virtual networks include the following:

- Virtual machines support an unlimited number of virtual networks. Also, be aware that an unlimited number of virtual machines can be connected to a virtual network.
  - Multiple virtual networks can be associated with a single physical network adapter.
  - When a virtual network is created, its configuration is dependent on the configuration and physical hardware (such as the type and number of network adapters) of the host operating system.
  - The physical devices are partitioned into one or more virtual devices, depending on the network necessity and the device's capability.
  - When setting up a new virtual device, the system administrator will define how much of the physical device capability each partition will have. This means that one physical server could act as two or three virtual machines that work separately from one another and have their own specifications.
  - The available resources in a network are split up so the available bandwidth is turned into channels. Each channel can be assigned to a particular server or device in real-time. Each channel is independently secured.
- A virtual network includes a virtual Dynamic Host Configuration Protocol (DHCP) server that can provide IP address leases only to virtual machines. Even though the DHCP server is isolated, it assigns unique IP addresses from the range specified.
- Accessing a network and network resources requires that the operating system on the virtual machine be configured as a part of the network.
- Internal network virtualization configures a single system with software containers, or pseudo-interfaces, to emulate a physical network with software. This can improve a single system's efficiency by isolating applications to separate containers or pseudo-interfaces.
- External network virtualization combines one or more LANs into virtual networks to improve a large network's efficiency. Using this technology, systems physically attached to the same local network can be configured to be separate virtual networks. Systems from separate LANs can also be combined into a single VLAN that spans segments of a large network.
- Network virtualization should allow a virtual network, including all of its IP addresses, routes, network appliances, and so on, to appear to be running directly on the physical network. This allows the servers connected to that virtual network to continue to operate as if they were running directly on the physical network, even though multiple virtual networks share the physical network.

Network Virtualization Providers

Some of the main network virtualization service providers are:

Provider	Description
VMware	Be aware of the following regarding VMware solutions. VMware introduced the first x86 server virtualization products in 2001, making it a virtualization pioneer. VMware desktop software runs on Microsoft Windows, Linux, and macOS. In contrast, its enterprise software hypervisor for servers, VMware ESXi, is a bare-metal hypervisor that runs directly on server hardware without requiring an additional underlying operating system. ESXi is primarily used for data center virtualization.
Microsoft	Microsoft solutions include: Hyper-V Network Virtualization that provides virtual networks to virtual machines. This is similar to how server virtualization (hypervisor) provides virtual machines to the operating system. Hyper-V Network Virtualization has high scalability, with a capacity for over 1,000 virtual machines per host. Microsoft Azure that provides network virtualization in the cloud.
Citrix	Citrix virtualization solutions: Provide a virtualization solution called XenServer, also referred to as Citrix Hypervisor. Support the widest range of graphics applications. Support Intel GVT-g GPU virtualization, a CPU-embedded GPU requiring no additional hardware.

10.2.5 Virtual Networking Facts

This lesson covers the following topics:

- Virtual networks
- Virtual networking devices

Virtual Networks

A virtual network is a computer network consisting of virtual and physical devices. Organizations generally use virtual devices to save money. By using less physical storage space, a company is able to have considerably more devices in a network while using very little space in a data center. With virtualization, companies can take advantage of the efficiencies and agility of software-based devices and storage resources.

The physical networking devices are responsible for the forwarding of packets, while the virtual network (software) provides an intelligent abstraction that makes it easy to deploy and manage network services and underlying network resources.

The following are some network virtualization terms to be familiar with:

Term	Description
Virtual local area network (VLAN)	Several physical LANs can function as a single logical LAN or the partitioned network can be on a single router.
Virtual area network (VAN)	This is a virtual LAN running on top of a physical LAN. This configuration enables guest virtual machines on separate physical hosts to communicate.
Virtual private network (VPN)	A VPN is usually used as a secure tunnel over another network, connecting multiple remote end-points, such as routers. A multipoint VPN is a VPN connecting more than two end-points.
Virtual machine (VM)	VMs are virtual computers that function like a physical computer. Virtual servers are virtual machines capable of providing services such as databases, email, domains, and applications. The traffic between virtual machines can be routed using virtual switches alongside virtual routers and virtual firewalls for network segmentation and data isolation.

Virtual Networking Devices

The following table describes virtual networking devices that can be used to create a more secure network.

Device	Description
Virtual switch (vSwitch)	Software that facilitates the communication between virtual machines by checking data packets before moving them to a destination. A vSwitch may be a part of software installed in the virtual machine or part of the server firmware.
Virtual router (vRouter)	A software function that replicates the functionality of a physical router. Because virtual routing liberates the IP routing function from specific hardware, you can more freely move routing functions around a network.
Virtual firewall appliance (VFA)	Software that functions as a network firewall device that provides the usual packet filtering and monitoring. The VF can run as a traditional software firewall on a virtual machine.
Virtual machine monitor/hypervisor (VMM/hypervisor)	Software, firmware, or hardware that creates and runs virtual machines. A computer on which a hypervisor runs to provide one or more virtual machines is called a host machine. Each virtual machine is called a guest machine. The hypervisor provides the guest operating systems with a virtual operating platform and manages the execution of the guest operating systems.

10.2.6 Create Virtual Switches (Simulation)

Scenario

You have installed Hyper-V on the CorpServer server. You want to use the server to create virtual machines. Prior to creating the virtual machines, you are experimenting with virtual switches.

In this lab, your task is to:

Create an internal virtual switch named *Switch 1.*

Create a private virtual switch named *Switch 2.*

Explanation

Complete this lab as follows:

Open the Virtual Switch Manager.

From Hyper-V Manager, right-click **CORPSERVER** .

Select **Virtual Switch Manager** .

Create an internal switch named *Switch 1* .

Select **Create Virtual Switch** .

In the Name field, enter **Switch 1** .

Under Connection type, select **Internal network** .

Select **Apply** .

Create a private switch named *Switch 2* .

From the left pane, select **New virtual network switch** .

From the right pane, select **Private** .

Select **Create Virtual Switch** .

In the Name field, enter **Switch 2** .

Select **OK** .

10.2.7 Practice Questions (Section Quiz)

q_virt_impl_citrix_secp8

Which of the following provides the network virtualization solution called XenServer?

Answers:

Microsoft

***Citrix**

VMWare

Cisco

Explanation:

Citrix provides a virtualization solution called XenServer, also referred to as Citrix Hypervisor.

Microsoft provides a virtualization solution called Hyper-V Network Virtualization.

VMWare provides a virtualization solution called ESXi.

Cisco does not provide a virtualization solution but does offer a vSwitch platform called Nexus 1000v.

q_virt_impl_hyper-v_secp8

You are a system administrator for a large corporation that is planning to implement network virtualization across its data centers.

The corporation has a high demand for scalability, with the need to support over 1,000 virtual machines per host. The corporation also has a significant investment in Microsoft technologies and wants to leverage existing resources and expertise.

Which network virtualization provider should you recommend?

Answers:

VMware

***Hyper-V**

Citrix

VLAN

Explanation:

Hyper-V Network Virtualization is the correct answer. It provides virtual networks to virtual machines, similar to how server virtualization provides virtual machines to the operating system. It has high scalability, with a capacity for over 1,000 virtual machines per host, which matches the corporation's needs. Additionally, as a Microsoft solution, it would allow the corporation to leverage its existing investment in Microsoft technologies and expertise.

While VMware is a pioneer in virtualization and offers robust solutions, it may not be the best fit for a corporation with a significant investment in Microsoft technologies. VMware's ESXi is primarily used for data center virtualization, but the question does not provide information about the need for this specific feature.

Citrix is a company that sells virtualization software that enables users to work from remote locations. However, it uses Xen server as its hypervisor, which makes it difficult to use with Microsoft technologies, including existing resources and expertise.

VLAN, or Virtual Local Area Network, is a network topology configuration that allows for the partitioning and isolation of devices in a larger network. While it can be used in conjunction with network virtualization, it is not a network virtualization provider itself.

q_virt_impl_micro_secp8

Which of the following is a network virtualization solution provided by Microsoft?

Answers:

VMware

VirtualBox

***Hyper-V**

Citrix

Explanation:

Hyper-V Network Virtualization provides virtual networks to virtual machines. This is similar to how server virtualization (hypervisors) provides virtual machines to the operating system. Hyper-V Network Virtualization has high scalability, with the capacity for over 1,000 virtual machines per host.

None of the other virtualization solutions are provided by Microsoft.

q_virt_impl_virtual_networking_01_secp8

You are a system administrator for a large corporation that is planning to implement virtual networking to improve efficiency. You have been tasked with setting up a new virtual device.

Which of the following steps would be the most appropriate to ensure optimal utilization of the physical device capability?

Answers:

Assign all available resources of the physical device to the new virtual device.

***Partition the physical device into multiple virtual devices, each with a portion of the physical device's capability.**

Assign a small portion of the physical device's resources to the new virtual device to ensure other devices can also use the resources.

Avoid partitioning the physical device and use it as a single virtual device.

Explanation:

Partitioning the physical device into multiple virtual devices, each with a portion of the physical device's capability, is correct. This allows for optimal utilization of the physical device's resources as it ensures that each virtual device has the resources it needs without monopolizing the entire physical device.

Assigning all available resources of the physical device to the new virtual device is incorrect. This would not allow for optimal utilization as it would prevent other virtual devices from using the physical device's resources, potentially leading to resource wastage if the new virtual device does not require all the resources.

Assigning a small portion of the physical device's resources to the new virtual device to ensure other devices can also use the resources is incorrect. While it is important to ensure that resources are available for other devices, assigning a small portion may not provide the new virtual device with the resources it needs to function effectively.

Avoiding partitioning the physical device and using it as a single virtual device is incorrect. This would not allow for optimal utilization of the physical device's resources as it would prevent the creation of additional virtual devices, limiting the overall efficiency and flexibility of the network.

q_virt_impl_virtual_networking_02_secp8

As a network administrator for a tech startup, you are tasked with improving the efficiency of a single system that runs multiple applications.

The system is currently experiencing performance issues due to the applications competing for network resources.

Which type of network virtualization would be the most appropriate solution in this scenario?

Answers:

External network virtualization

Virtual Private Network (VPN)

Virtual Local Area Network (VLAN)

***Internal network virtualization**

Explanation:

Internal network virtualization is correct. This type of virtualization configures a single system with software containers, or pseudo-interfaces, to emulate a physical network with software. This can improve a single system's efficiency by isolating applications to separate containers or pseudo-interfaces, thus reducing competition for network resources.

External network virtualization is incorrect. This type of virtualization is used to combine one or more LANs into virtual networks to improve a large network's efficiency. It is not typically used for improving the efficiency of a single system running multiple applications.

Virtual Private Network (VPN) is incorrect. While a VPN can provide secure access to a private network from a remote location, it does not specifically address the issue of improving the efficiency of a single system running multiple applications.

Virtual Local Area Network (VLAN) is incorrect. A VLAN is used to group workstations that are not within the same geographical location into the same broadcast domain. It does not specifically address the issue of improving the efficiency of a single system running multiple applications.

q_virt_impl_vmware_esxi_secp8

Which of the following is a bare-metal hypervisor that runs directly on server hardware without requiring an additional underlying operating system and is primarily used for data center virtualization?

Answers:

VMware Workstation

***VMware ESXi**

VMware Fusion

VMware Horizon

Explanation:

VMware ESXi is correct because it is a bare-metal hypervisor that runs directly on server hardware without requiring an additional underlying operating system. It is primarily used for data center virtualization.

VMware Workstation is incorrect because it is a hosted hypervisor that runs on x64 versions of Windows and Linux operating systems, allowing users to set up virtual machines (VMs) on a single physical machine and use them simultaneously along with the actual machine.

VMware Fusion is incorrect because it is a software hypervisor developed by VMware for Macintosh computers with Intel processors, allowing users to run Windows, Linux, and other operating systems simultaneously with Mac OS X on Intel-based Macs.

VMware Horizon is incorrect because it is a product suite that provides virtual desktops and applications to end users. It does not run directly on server hardware without an underlying operating system.

q_virt_net_network_secp8

Which of the following statements about virtual networks is true? (Select two.)

Answers:

A virtual network is independent of the configuration and physical hardware of the host operating system.

***A virtual network is dependent on the configuration and physical hardware of the host operating system.**

Each virtual network must be associated with a single physical network adapter.

***Multiple virtual networks can be associated with a single physical network adapter.**

Accessing network resources requires that the operating system on the virtual machine be configured on an isolated network.

Explanation:

A virtual network is made up of one or more virtual machines configured to access local or external network resources. Some important facts about virtual networks include:

Virtual machines support an unlimited number of virtual networks, and an unlimited number of virtual machines can be connected to a virtual network.

Multiple virtual networks can be associated with a single physical network adapter.

When a virtual network is created, its configuration is dependent on the configuration and physical hardware (such as the type and number of network adapters) of the host operating system.

Accessing a network and network resources requires that the operating system on the virtual machine be configured as a part of the network.

q_virt_net_switch_secp8

Which of the following devices facilitates communication between different virtual machines by checking data packets before moving them to a destination?

Answers:

***Virtual switch**

Virtual router

Virtual firewall

Hypervisor

Explanation:

A virtual switch is software that facilitates the communication between different virtual machines. It does so by checking data packets before moving them to a destination. They may already be a part of software installed in the virtual machine, or they may be part of the server firmware.

A virtual router is a software function that replicates the functionality of a physical router and contributes to the functioning of a virtual switch. However, it does not focus on checking data packets before moving them to a destination.

A virtual firewall is software that functions as a network firewall device that provides the usual packet filtering and monitoring. It does not check data packets before moving them to a destination.

The hypervisor is software, firmware, or hardware that creates and runs virtual machines, including virtual switches.

q_virt_net_van_secp8

Which of the following is a virtual LAN that runs on top of a physical LAN?

Answers:

VLAN

***VAN**

VFA

VMM

Explanation:

A virtual area network (VAN) is a virtual LAN running on top of a physical LAN. This configuration enables guest virtual machines on separate physical hosts to communicate.

VLANs allow several physical LANs to function as a single logical LAN.

A VFA is a virtual firewall appliance. This is software that functions as a network firewall device.

A virtual machine monitor is software, firmware, or hardware that creates and runs virtual machines. This is also known as a hypervisor.

q_virt_net_vfa_secp8

Which of the following virtual devices provides packet filtering and monitoring?

Answers:

VLAN

vSwitch

***VFA**

VMM

Explanation:

A VFA is a virtual firewall appliance. This is software that functions as a network firewall device that provides the usual packet filtering and monitoring. A VFA can run as a traditional software firewall on a virtual machine.

VLANs allow several physical LANs to function as a single logical LAN.

A vSwitch is software that facilitates the communication between virtual machines by checking data packets before moving them to a destination.

A virtual machine monitor is software, firmware, or hardware that creates and runs virtual machines. This is also known as a hypervisor.

q_virt_net_vlan_secp8

Which of the following is an example of protocol-based network virtualization?

Answers:

***VLAN**

vSwitch

VFA

VMM

Explanation:

VLANs and VPNs are two examples of protocol-based network virtualization.

A vSwitch is software that facilitates the communication between virtual machines by checking data packets before moving them to a destination.

A VFA is a virtual firewall appliance. This is software that functions as a network firewall device.

A virtual machine monitor is software, firmware, or hardware that creates and runs virtual machines. This is also known as a hypervisor.

q_virt_net_vpn_secp8

Which of the following is used as a secure tunnel to connect two networks?

Answers:

VLAN

VAN

VFA

***VPN**

Explanation:

A virtual private network (VPN) is usually used as a secure tunnel over another network, connecting multiple remote endpoints (such as routers). A multipoint VPN is a VPN connecting more than two endpoints.

VLANs allow several physical LANs to function as a single logical LAN.

A virtual area network (VAN) is a virtual LAN running on top of a physical LAN.

A VFA is a virtual firewall appliance. This is software that functions as a network firewall device.

10.3 Software-Defined Networking

As you study this section, answer the following questions:

Which three layers exist in the software-defined networking (SDN) architecture?

What is the function of the controller?

What technology allows network and security professionals to manage, control, and make changes to a network?

What are the advantages of SDN?

What are the disadvantages of SDN?

Key terms for this section include the following:

Term	Definition
Software-defined networking	An architecture that allows network and security professionals to manage, control, and make changes to a network.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts Software-defined networking (SDN)

10.3.1 Software-Defined Networking Basics (Lesson Video)

Transcript:

Even though software-defined networking, also know as SDN, is a relatively new approach to networking, its use has grown exponentially the last few years.

The idea behind SDN is that network engineers should be able to use software to configure and intelligently control the network, rather than relying on the individual static configuration files that are located on each network device. By using SDN, network engineers are given the ability and flexibility to control their networks programmatically in order to accommodate rapidly changing environments.
For example, let's say you work in a datacenter. In this datacenter, you need a lot of equipment to create a network servers, switches, bridges, load balancers, cables, et cetera.
All of these devices are highly capable of making truly intelligent decisions within their individual capabilities. However, they require individual configurations on each of the devices. And if you need to make a change that affects multiple devices, then you need to manually make that change on each of these devices. In addition, making all of these devices work together perfectly can be a bit of a headache. For example, devices from different vendors might not work properly with each other.
With SDN, however, the configuration, management, and communication of all these devices is standardized and centralized. Software-defined networking takes all of these devices and combines them in much the same way a computer combines internal hardware components. It does this by using what's called a software-defined network controller.
An SDN controller functions a lot like traditional desktop operating system. It is able to inventory hardware components in the network, gather network statistics, make routing decisions based on gathered data, and facilitate communication between devices from different vendors. It can also be used to make wide-spread configuration changes on just one device. In essence, it's sort of like an operating system for the network.
For example, take our datacenter here. Let's say this datacenter suddenly gets an influx of user connections, and it needs to spin up new virtual machines to handle the load. Or perhaps it needs to offload some of these connections to another datacenter.
In a traditional networking environment, spinning up new VMs, routing connections to these VMs, and propagating these changes throughout the network could take too much time, and users wouldn't be able to use their resources.
With SDN, however, this influx of users is identified by the controller. The network administrator can then make configuration changes on the controller to redirect users to the new VMs. And because all these configurations are controlled at a central location the controller they are propagated out to the network almost instantaneously, allowing the

users to have no interruption in their connections. When the influx of user connections returns to normal, the controller can then return the network to the state it was in before.
One of the primary advantages to using an SDN controller is that it can also act autonomously in situations like this. For example, if this scenario occurs again, the controller can remember the actions that were taken and perform them automatically.
So, it's pretty easy to see why software-defined networking is here to stay.
That's it for this lesson. In this lesson, we learned the basics of software-defined networking, including how it works and how the controller communicates with network devices and responds to events like an influx of user connections.

10.3.2 SDN Infrastructure and Architecture (Lesson Video)

Transcript:

In this lesson, we're going to take a deeper look at software-defined networking, or SDN. We'll go over how software-defined networking can enhance your infrastructure to be more responsive, scalable, and secure.

In a previous lesson, we looked at how the SDN controller can respond to changing network conditions and make changes to data flow. Let's take a look at the underlying SDN architecture to see how this is done.
So, we have our controller right here. Remember, the controller itself is just a software platform that contains other applications it's the network's operating system.
The SDN architecture consists of three layers. In the middle, there's the control layer. This is where the controller resides.
Above that is the application layer. This is where various applications reside. One of these could be an app that creates a network map of all the devices in your network. Another one could be a load balancer that stops and starts VMs as resource use increases.
The application layer and these various apps communicate with the control layer through what's called the northbound interface. These are sometimes called northbound APIs.
Below the control layer is the physical layer. This is where the physical networking devices reside. Even though it's called the physical layer, it's also where the virtual networking devices reside. The physical layer communicates to the control layer through the southbound interface. The individual networking devices use southbound APIs to communicate with the control plane, and vice versa.
Understand that this control layer, the control plane, removes that control plane from the physical networking devices. In traditional networks, each of these devices would have an integrated control plane located on the device. However, SDN removes this from the devices and creates a single control plane.
There's one last thing to be aware of regarding software-defined networks. As with the implementation of any new feature or technology, the transition comes with some inherent challenges.
For example, a centralized controller introduces a new target for attackers. Imagine a third-party application that uses the northbound API to gain complete knowledge of your entire network. That could be very dangerous. Therefore, it's important to be aware of proper security techniques and how these interfaces can be compromised.
That's it for this lesson. In this lesson, we took a deeper look into software-defined networking, or networking programmability. We also talked about some of the security concerns you need to be aware of with SDN.

10.3.3 SDN Facts

This lesson covers the following topics:

- Software-defined networking (SDN)
- SDN advantages and disadvantages

Software-Defined Networking (SDN)

Software-defined networking (SDN) is a recent technology that allows network and security professionals to manage, control, and make changes to a network. The idea is that network engineers are able to use software to configure and intelligently control the network rather than relying on the individual static configuration files located on each network device.

SDN uses a controller to manage the devices. The controller is software that is able to inventory hardware components in the network, gather network statistics, make routing decisions based on gathered data, and facilitate communication between devices from different vendors. It can also be used to make widespread configuration changes on just one device.

The SDN architecture consists of three layers. The table below shows the functions:

SDN Layer	Function
Application layer	The Application layer communicates with the Control layer through what is called the northbound interface. These are sometimes called northbound APIs.
Control layer	The Control layer receives its requests from the Application layer and then provides the Physical layer with its configuration and instructions.
Physical layer	The Physical layer, also known as the Infrastructure layer, communicates to the Control layer through the southbound interface. The individual networking devices use southbound APIs to communicate with the control plane and vice versa. Even though this layer is called the Physical layer, it is where both physical and virtual network devices sit.

This architecture allows for fully automated deployment (or provisioning) of network links, appliances, and servers. This makes SDN an important part of the latest automation and orchestration technologies.

SDN Advantages and Disadvantages

Some advantages of SDN include:

- Centralized management
- More granular control
- Lower overall cost and labor
- Give new life to old networking hardware
- Gather network information and statistics
- Facilitate communication between hardware from different vendors

Some disadvantages of SDN include:

- It is currently a new technology
- Lack of vendor support
- Standards are still being developed

Centralized control opens a new target for security threats

10.3.4 Practice Questions (Section Quiz)

q_sdn_advantage_secp8

Which of the following is an advantage of Software Defined Networking (SDN)?

Answers:

It's currently a new technology.

Standards are still being developed.

***More granular control.**

It lacks vendor support.

Explanation:

One of the advantages of SDN is more granular control.

Some disadvantages of SDN include:

It's currently a new technology.

It lacks vendor support.

Standards are still being developed.

q_sdn_app_01_secp8

Which of the following BEST describes the Application SDN layer?

Answers:

Communicates with the Control layer through the Southbound Interface.

***Communicates with the Control layer through the Northbound Interface.**

Receives requests and then provides configuration and instructions.

Is software that is able to inventory hardware components in the network.

Explanation:

The Application layer communicates with the Control layer through what is called the Northbound Interface. These are sometimes called Northbound APIs.

The Physical layer, also known as the Infrastructure layer, communicates with the Control layer through the Southbound Interface.

The Control layer receives requests from the Application layer and then provides the Physical layer with its configuration and instructions.

The controller is software that is able to inventory hardware components in the network.

q_sdn_app_02_secp8

Which SDN layer would a load balancer that stops and starts VMs as resource use increases reside on?

Answers:

Physical

***Application**

Session

Control

Explanation:

Applications reside on the Application layer. A load balancer that stops and starts VMs as resource use increases is an example of an application that would reside on this layer.

The Physical layer is where both physical and virtual network devices sit.

The Session layer is the fifth layer of the OSI model.

The Control layer is the middle layer. This is where the controller resides.

q_sdn_controller_secp8

Software Defined Networking (SDN) uses a controller to manage devices. The controller is able to inventory hardware components on the network, gather network statistics, make routing decisions based on gathered data, and facilitate communication between devices from different vendors. It can also be used to make widespread configuration changes on just one device.

Which of the following BEST describes an SDN controller?

Answers:

***The SDN controller is software.**

The SDN controller is hardware.

The SDN controller is a virtual networking device.

The SDN controller is a networking protocol.

Explanation:

SDN uses a controller to manage devices. The controller is software that is able to inventory hardware components on the network, gather network statistics, make routing decisions based on gathered data, and facilitate communication between devices from different vendors. The controller can also be used to make widespread configuration changes on just one device.

SDN is not a virtual networking device, a networking protocol, or hardware.

q_sdn_def_secp8

A company is deploying a software service to monitor traffic and enforce security policies in its cloud environment.

Considering the need for responsiveness, which technology should the company consider using?

Answers:

***Serverless platforms and Software Defined Networking (SDN)**

Infrastructure as code (IaC)

Microservices

Virtual private cloud (VPC)

Explanation:

Serverless platforms allow the company to focus on application development by managing the underlying infrastructure, while SDN helps in efficient traffic monitoring and security policy enforcement.

While IaC is ideal for automated and consistent deployment and management of infrastructure, it does not inherently provide traffic monitoring or security policy enforcement. Furthermore, IaC may not ensure system responsiveness.

Although microservices support modular and independent application development, they do not directly address traffic monitoring, security policy enforcement, or system responsiveness requirements.

Traditional VPC offerings provide some level of security in a cloud environment but may lack the flexibility, scalability, and efficiency of serverless platforms. Additionally, they do not inherently offer effective traffic monitoring or system responsiveness.

q_sdn_layer_secp8

Drag the software defined networking (SDN) layer on the left to the appropriate function on the right. (Each SDN layer may be used once, more than once, or not at all.)

Answers:

Application layer

Control layer

Physical layer

Explanation:

The SDN architecture consists of three layers:

Application layer - communicates with the Control layer through the northbound interface. These are sometimes called northbound APIs.

Control layer - receives its requests from the Application layer and then provides the Physical layer with its configuration and instructions.

Physical layer - communicates with the Control layer through the. southbound interface. The individual networking devices use southbound APIs to communicate with the control plane and vice versa. Even though this is called the Physical layer, it is where both physical and virtual network devices sit. It is also known as the Infrastructure layer.

q_sdn_north_secp8

Which of the following does the Application layer use to communicate with the Control layer?

Answers:

***Northbound APIs**

Controllers

Southbound APIs

These layers do not communicate

Explanation:

The Application layer communicates with the Control layer through what is called the Northbound Interface. These are sometimes called Northbound APIs.

The controller is just a software platform that contains other applications. It can be thought of as the network's operating system.

The individual networking devices on the Physical layer use Southbound APIs to communicate with the control plane and vice versa.

The Application and Control layers do communicate.

q_sdn_phys_secp8

Which of the following BEST describes the Physical SDN layer?

Answers:

***Also known as the Infrastructure layer.**

Sometimes called Northbound APIs.

Receives its requests from the Application layer.

Gives new life to old networking hardware.

Explanation:

The Physical layer is also known as the Infrastructure layer.

The Application layer is sometimes called a Northbound API.

The Control layer receives its requests from the Application layer.

One advantage of SDN is that it gives new life to old networking hardware.

q_sdn_software_secp8

Network engineers have the option of using software to configure and control the network rather than relying on individual static configuration files that are located on each network device.

Which of the following is a relatively new technology that allows network and security professionals to use software to manage, control, and make changes to a network?

Answers:

***Software Defined Networking (SDN)**

Control layer networking

Load balancing software

Infrastructure software networking

Explanation:

Software Defined Networking (SDN) is a relatively new technology that allows network and security professionals to manage, control, and make changes to a network. Network engineers are able to use software to configure and control the network rather than relying on individual static configuration files that are located on each network device.

The Control layer is one of three layers that comprise Software Defined Networking. The other layers are the Application layer and the Physical layer.

Load balancers can be a component of the Application layer.

The Physical layer can also be referred to as the Infrastructure layer.

q_sdn_south_secp8

Which APIs do individual networking devices use to communicate with the control plane from the Physical layer?

Answers:

Northbound

Northbound and Southbound

***Southbound**

None

Explanation:

Individual networking devices on the Physical layer use Southbound APIs to communicate with the control plane and vice versa.

The Application layer communicates with the Control layer through what is called the Northbound Interface.

q_sdn_standards_secp8

Which of the following is a disadvantage of Software Defined Networking (SDN)?

Answers:

***SDN standards are still being developed.**

SDN creates centralized management.

SDN gathers network information and statistics.

SDN facilitates communication between hardware from different vendors.

Explanation:

Some of the disadvantages of SDN include:

Still a newer technology

Lack of vendor support

Standards are still being developed

Centralized control opens a new target for security threats

Some of the advantages of SDN include:

Centralized management

More granular control

Lower overall cost and labor

Gives new life to old networking hardware

Gathers network information and statistics

Facilitates communication between hardware from different vendors

10.4 Cloud Services

As you study this section, answer the following questions:

What is the difference between a hybrid cloud and a community cloud?

What is the difference between infrastructure as a service (IaaS) and platform as a service (PaaS)?

Which two implementations are available for software as a service (SaaS)?

What services does cloud computing provide?

Which cloud computing model allows the client to run software without purchasing servers, data center space, or network equipment?

Key terms for this section include the following:

Term	Definition
Cloud	A metaphor for the internet.
Cloud computing	Software, data access, computation, and storage services provided to clients through the internet.
Public cloud	A cloud that is deployed for shared use by multiple independent tenants.
Private cloud	A cloud that is deployed for use by a single entity.
Community cloud	Platforms, applications, storage, or other resources that are shared by several organizations.
Hybrid cloud	A cloud deployment that uses both private and public elements.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.2 Summarize fundamental security concepts. Authentication, Authorization, and Accounting (AAA) Authenticating people 2.2 Explain common threat vectors and attack surfaces. Supply chain Managed service providers (MSPs) Vendors

	Suppliers 2.3 Explain various types of vulnerabilities. Cloud-specific Supply chain Service provider 3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts Cloud Hybrid considerations Third-party vendors Serverless Virtualization Considerations 4.1 Given a scenario, apply common security techniques to computing resources. Hardening targets Cloud infrastructure 5.3 Explain the processes associated with third-party risk assessment and management. Vendor assessment Penetration testing Right-to-audit clause Independent assessments Vendor monitoring

10.4.1 Cloud Services Introduction (Lesson Video)

Transcript:

More and more networks are shifting to a decentralized resource approach by utilizing various cloud services. Because of this, it's important that you have a solid understanding of cloud concepts and how cloud services impact a network.

Chances are you've heard about the cloud. It's used in almost every conversation about networking or the internet. But what exactly is the cloud? Well, it's actually a lot of different things and a lot of them have been around for a while.
Let's say we have an enterprise network here. And within this network, we have several switches, routers, some servers, workstations, and a connection to the internet. Traditionally, each of these workstations would have all the necessary applications and hardware components in order to carry out daily tasks, and these servers would each have a single OS installed and provide a specific function, such as a file server or DHCP server.
However, the cloud changes how a traditional network model works. For example, let's say these workstations need to perform a lot of calculations. In a traditional networking model, each of these workstations would need the necessary software and hardware to match to carry out these tasks. That can get expensive. What the cloud does is outsource these tasks to other machines, which are either located on the same network or provided by a third party via the Internet.
In essence, the cloud is computing resources that are offered or delivered as a service over a network. These computing resources include performing calculations or computations, the ability to store data, or the ability to network resources together. The cloud name itself comes from the cloud-shaped symbol used to denote a complex infrastructure in system and network diagrams.
In order for a service to be considered a true cloud service, it needs to have five characteristics, which have been determined by the National Institute of Standards and Technology.
First, it needs to be an on-demand self-service, meaning users must be able to dynamically obtain resources.
Second, it needs to be provided over a network, typically the Internet, and be available on multiple platforms, such as mobile phones, tablets, laptops, and workstations. This is called broad network access.
Third, it needs to have resource pooling. This means multiple users can use the same resources. These resources can be physical or virtual, but they need to be able to scale dynamically according to demand. For example, if a server suddenly gets a thousand connections, it needs the ability to provision additional computing power or offload clients to different VMs or servers.
Fourth, the service needs to have rapid elasticity. This means the services can seamlessly provision resources and scale resource usage back depending on demand.
And finally, the fifth characteristic is what's known as a measured service--that is, resources can be controlled and optimized automatically. In addition, this also means that the service provider can collect information about the service.
Now, cloud services can be categorized based on the way they are deployed, and there are a few different cloud deployment models you should know about. The first is a public cloud.
A public cloud is made available to the public by a service provider. These services are sometimes free, but often use a pay-as-you-go model.
With a private cloud, the service consists of an infrastructure provisioned and operated solely for a single organization. Private clouds are typically hosted at the organization. However, there are some private cloud providers that provide remote hosting.
Sometimes several organizations share infrastructure for a specific community with common concerns. This is called a community cloud.
And the final cloud deployment model is a hybrid cloud. Hybrid clouds are becoming increasingly common. Hybrid clouds are a combination of private, community, or public clouds for different aspects of the services that are provided. For instance, a hybrid cloud service can provide special load balancing between different cloud types if there is a spike in resource usage. Hybrid clouds also use both on-site and off-site resource hosting.
Now that you have an understanding of some of the basic concepts of the cloud service model, let's take a look at the different types of cloud services that are available to organizations.
The first cloud service we'll look at is called Infrastructure as a Service (IaaS).
I want to point out that all cloud services end with as a service. This is a quick way for you to identify a cloud service. They almost all use this initialism model, too.
Now, Infrastructure as a Service provides an organization with infrastructure components that is, computer hardware components as a service. And these hardware components can be anything from networking devices to storage and data processing resources.
For example, instead of having to install multiple file servers with redundant hard drives in your server room, you can pay a company for storage space on their servers. This eliminates the need to maintain and secure local file servers.
And let's say you need to process large amounts of data or compile and test applications. Instead of needing the hardware infrastructure on site, you can outsource this to an IaaS company, such as AWS.

Another nice thing about IaaS is that it can scale as needed. For example, let's say you need to add more computing resources. Without IaaS, you would have to go out and buy all that hardware, set it up, configure it, et cetera. However, if you are using IaaS, you just tell the cloud company that you need more resources, and they are immediately provided.
One thing to know about using IaaS is that it only provides the hardware resources. It's still your job to handle all the configuration and setup and interface with the cloud infrastructure.
The next cloud service is Platform as a Service (PaaS).
Platform as a Service provides all the underlying resources that IaaS provides; however, it goes a step further. In addition to the hardware resources, PaaS also provides the configuration, setup, and management of the cloud platform. For example, it handles installing operating systems, connecting virtual networks, and creating an entire environment that is ready for you to use immediately. One common example of PaaS is for software developers. A lot of companies that offer PaaS have packages that are specifically designed for developing, testing, and deploying software programs. Some PaaS cloud service providers also provide additional features, such software design systems, software development resources, testing, and deployment resources. Like IaaS, PaaS provides scalability and flexibility; it can grow or shrink with your organization's needs.
Next is Software as a Service (SaaS). Software as a Service is designed for your average end user. It provides end users with the applications that they need to perform their day-to-day work.
Instead of installing the applications locally, they use a web browser to access programs. Some SaaS providers charge a monthly or annual fee. But often, with SaaS, you pay for only the applications that you need. For example, if a user needs a word processing application for nine hours a day, that is how much you pay for. If another user needs the same application for only three hours a month, you pay much less.
SaaS also allows you to try new software before committing to it. You can try it out, paying only for the time you use it. If you really like it, you can pay for more use. If you don't like it, you can look for something else without losing much money.
SaaS comes in two forms, simple multi-tenancy and fine-grained multi-tenancy. With simple multi-tenancy, each cloud service customer has their own dedicated resources segregated from other customers' resources.
Fine-grained multi-tenancy offers the same level of segregation as simple multi-tenancy, but all of the resources used by all customers are pooled together and shared. Your data is segregated, so other customers can't access it. However, your computing resources, applications, and other cloud resources are shared with other customers.
The last cloud service model we'll look at is Security as a Service (SECaaS).
Now, you might be thinking, wait a second, I'm a security professional--why would I want to outsource my security services to the cloud? This isn't what SECaaS does.
In one way, SECaaS is similar to SaaS it provides a subscription model for applications and software. However, instead of being used for productivity on workstations, the applications and software are specific to organizational security.
For example, you might subscribe to a SECaaS system that provides a high-level anti-virus detection service that includes continuous anti-virus updates. Other services provided by SECaaS include DDoS protection, intrusion detection, and authentication services. One of the most common SECaaS providers is CloudFlare.
SECaaS can sometimes be much more cost effective for an organization than having to purchase all the necessary hardware equipment and personnel to properly protect a network from viruses, malware, and instruction. However, it is still a necessity to have an on-site security professional.
The cloud is an extremely useful service that more and more organizations implement. Because of this, it's important that you understand the underlying structure of the cloud and what it means to your organization's systems and infrastructure. In addition, by better understanding the cloud deployment models, you can better protect your organization.

10.4.2 Enhancing Cloud Performance (Lesson Video)

Transcript:

In this video, we're going to look at five different ways the cloud is being enhanced with technologies for performance: fog computing, edge computing, serverless architecture, services integration, and resource policies. Let's get started.

Fog computing, also known as fogging, is the cloud plus the Internet of Things.
Fog is a new distributed architecture that extends services offered in the cloud to edge devices. Fog nodes are made up of intelligence, computing power, and storage resources. This can be in the form of routers or smart gateways that communicate with the cloud.

These fog nodes might, for example, process signals coming in from sensors in a certain part of a city to measure CO2 emissions and then send alerts.

Edge devices are designed to accomplish specific tasks using apps. They come in all shapes and sizes, from smartwatches to autonomous cars to smart buildings. Edge devices can also be routers, switches, or firewalls. Fog computing uses decentralized local network architectures to speed up the analysis and retrieval of data near the source. With growing 5G Wireless networking and embedded artificial intelligence, we're about to have billions of apps and devices coming online and a tsunami of data that needs to be processed. Fog can help with that.

With fog, critical core functions are distributed. Computing, communications, control, storage, and decision making are all close to where the data originates locally. Smart devices and sensors are being developed so the components can instantly interact via wireless networks.

Fog promises to be a revolutionary new way of connecting, living, and working. Its benefits over cloud computing include lower latency, greater security, and enhanced capacity. Since fog nodes are physically closer to devices in the network, users can enjoy much lower latency with instant responses to their computing needs.

Fog provides greater security mainly because the data travels a much shorter distance in a distributed network. With fog, the storage capacity of the cloud is also enhanced. For example, a smart vehicle in trial right now is currently generating 35 gigabytes of data per hour. Secure fog computing has the power and reach to process this amount of data.

In addition, fog has the monitoring, detecting, and reporting capabilities to provide real-time incident response for security breaches, allowing it to quickly detect and isolate threats and minimize disruption of services.

While fog computing has many positive aspects, it also inherits a cornucopia of security issues from cloud computing: account hijacking, denial of service, access control issues, unsecure APIs, system and application vulnerabilities, shared technology issues, and much more.

Now let's discuss Edge computing. Edge computing is performed at or near the source of the data, not in the cloud. It's a component of fog computing where the architecture is distributed with decentralized processing power. We capture, store, process, and analyze the data near the client, where the data is usually generated.

From the wearable on your wrist to streaming video optimization, from controlling intersection traffic flow to smart homes and buildings, edge computing's future is exponentially expanding with the Internet of Everything, artificial intelligence, 5G, robotics, machine learning, and all the other technological developments taking place now.

For edge devices to be smart, they must look at incoming data, process it effectively, share it, and take some sort of action. Edge computing means the edge devices take these actions without requiring data to be transported elsewhere. Using a hub and spoke model, the cloud is the hub, and everything outside the spokes is the edge, like a spiderweb.

Think of it like this: edge computing is about processing the data locally, where cloud computing is focused on processing data in a remote data center that's a public or private cloud.

There are many benefits of edge computing. And much like fog computing, these include lower latency, increased bandwidth, greater resiliency, and data sovereignty.

Data sovereignty is the ability to own and manage your own data, and companies are very concerned about making sure their data remains theirs regardless of the technology they utilize.

Edge also empowers workloads that need processing in near real time, like autonomous cars communicating with each other. This speed and efficiency allows organizations to make more impactful and timely decisions, which reduces costs, helps them better engage with customers, and increases privacy.

Edge computing also suffers from many of the same security risks as fog and cloud computing.

Another way to enhancing cloud performance is by using serverless architecture, or serverless computing. It lets you build and run your apps and services without having to actually manage the infrastructure they run on. Yes, your apps are still running on a server, but you don't have to take care of it or its components.

Instead, your cloud provider takes care of all the server provisioning management, leaving your developers to focus on what they do best: creating their core product. And this saves them precious time and energy.

Basically, a serverless architecture eliminates most of the infrastructure management tasks of server provisioning, patching, OS and database maintenance, storage, and more. The cloud service provider takes care of fault tolerance and high availability.

Ultimately, serverless architecture reduces costs and frees the company and its developers to focus on product innovation and a faster time to market. This gives them great agility and responsiveness while they enjoy automatic application scaling and market competitiveness.

The serverless model is often referred to as Backend as a Service, or BaaS, meaning that companies simply pay for the resources consumed on the back end. Companies can also rent functions and compute runtimes, known as Function as a Service, or FaaS. This allows companies to execute application logic, but none of their data is stored. Major FaaS vendors are Amazon, Google, IBM, and Microsoft.

Benefits of cloud services integration include synchronized data and apps, increased agility, faster time to market, improved operational efficiency, reduced operational costs, increased flexibility, and scalability. Whether single-cloud or multi-cloud focused, businesses are enjoying the tremendous, feature-rich benefits of cloud services integration.
While there are many positive aspects to serverless, there are a few drawbacks.
The first is performance. Some code could suffer from latency because the cloud provider typically spins down the serverless code while it's not in use. If the code you need has to take time to start up, that will cause a delay. Also, serverless may not be appropriate for some workloads, like high-performance computing, due to resource limits.
The next drawback is security.
In serverless computing, the total attack surface is due to each component being an entry point to the serverless application. Some of these would include network sniffing, man-in-the-middle attack, phishing, SQL injection, DDoS, and code exploit. Further, because of limitations, companies can't implement an intrusion detection/prevention system, or IDS/IPS.
The next challenge is privacy. Many serverless environments use proprietary public cloud environments, and resources are often shared. To overcome this, serverless computing can be done on private clouds or even on-premeses, which allows companies full control over system privacy.
Integration with the cloud has really grown in popularity as Software as a Service solutions continue to increase. More businesses are running a hybrid mix of on-premises apps and SaaS apps, and this is creating a much greater need for innovative integration methods.
There are three major integration types of cloud technologies: cloud-to-cloud, cloud-to-on-prem, and a hybrid combination of the two. Data and app integration needs are the core concern when you're choosing from these strategies. Businesses can build their own integration solutions for their enterprise, or they can employ a third-party provider with a solution that's reusable, agile, and scalable. More than likely, integrating with the cloud could be far more cost-effective as well.
However, data and apps need to be protected from internal and external threats. Misconfigurations can open devastating security vulnerabilities. A good cloud access security broker, or CASB, can be a dedicated security solution that monitors and automates security configuration audits.
A resource policy is attached to a specific resource where you can specify who has access to it and what they can do with it. This helps to lock down applications and data on mobile devices and integrate with cloud resources. You can create policies in something like Microsoft Intune and then roll them out to all your users. This includes your users who would like to bring your own device, or BYOD.
You can keep your corporate apps and data secure and encrypted on these devices, regardless of the OS Android, IoS, or Windows. Policies are usually applied to groups of users or groups of devices. If you're using Microsoft Intune for your resource policies, you'll need to integrate with Azure Active Directory services in the Azure cloud.
That's it for this lesson. In this lesson, we looked at other technologies that enhance cloud performance like fog computing, edge computing, and serverless architecture. We also discussed services integration, and we ended by exploring resource policies. The cloud will continue to expand, and more options will become available to enhance its performance.

10.4.3 Cloud Computing Security Issues (Lesson Video)

Transcript:

Let's talk about cloud computing security issues. The benefits offered by cloud computingâ€”"the ability to use applications, platforms, and infrastructure as needed, and not use them when you don'tâ€”"is attractive. However, security is a key issue.

In a traditional system, you secure data behind layer after layer of security mechanismsâ€”"firewalls, ACLs, encryption, et cetera. And even after all that, it's still a challenge to keep your network safe. Add in the cloud component, and now all that data is being sent across the internet to a third-party organization who also needs to maintain their own system security.
Ultimately, the decision to utilize a cloud provider comes down to a partnership of trust. The cloud computing service provider has to ensure the security and privacy of your information. Security is part of the service they provide.
However, you, as a security administrator, are still responsible for protecting your company's data. One of the key things you need to remember is that industry and government regulations created to protect personal and business information still apply. Even though the data is being stored by the cloud computing provider, you're still responsible.

Whenever an organization is evaluating a move to the cloud, I always tell them that they need to approach the process of picking a cloud service provider in the same way they would buying a used car from a dealership. A used car may look great on the surface, but what you really need to be concerned with is what's under the hood. Take the same approach when selecting a cloud service provider.

Let's go over some of the key security considerations you need to keep in mind if you use a cloud service provider.

First, there's an issue of trust. You have to trust that your cloud service provider is good at information security. If your provider hasn't done a good job securing their environment, you could be in trouble. You can insist that the cloud services provider implement specific security measures, but you can't physically make them.

In addition, there's a monitoring issue. It's difficult to monitor security issues when your environment is provided by a cloud service provider. You're not on site, so you don't know what security issues they're facing. You don't see the midnight attack that they had to fight off last night. The cloud service provider probably doesn't want to let you know about it because they're afraid you might terminate their services.

Likewise, it's difficult to measure a cloud provider's degree of competence with information security because they probably don't want to expose their infrastructure to customers. Therefore, as we talked about with monitoring, it's hard to know how things are really going with your cloud computing environment. All you see really is the user interface.

Another thing to consider is authentication. Make sure that the cloud service provider authenticates everyone who's going to use the service. Don't choose the cloud service provider if they allow free access.

The next key thing to look for is partitioning. In other words, they make sure that your information and your data is kept completely separate from other customers' information and data. You don't want a fellow cloud computing customer gaining access to your data.

Within your organization, make sure that your individual users only have access to the applications that they need. Do not allow them to choose whatever they want to use.

One way to do this is to use a Cloud Access Security Broker (CASB). A CASB is a software tool or a service that sits between an organization and a cloud service provider. Its job is to make sure that all communication and access to the cloud service provider complies with the organization's security policies and procedures. For example, it might make sure devices connecting to the cloud meet certain security standards, such as full-device encryption, up-to-date malware protection, et cetera.

The next key thing to look for is updating. Make sure that the cloud service provider maintains a rigorous patch management program to ensure that the systems are updated. This will help protect your information from potential exploits.

After that, check out their processes. A good cloud computing service provider should have processes, policies, and procedures in place to handle various events. These processes, policies, and procedures should include everything, from something as simple as requesting access to a new application or something as critical as dealing with a major security breach. When you're evaluating a company, ask the company for a copy of these policies and procedures so you can see what they are going to do if a certain event happens.

In addition, verify that the cloud service provider has policies and procedures in place for monitoring security logs, monitoring unusual behavior, and performing the various tasks required to keep their system safe.

Next, make sure that they use some form of encryption to ensure that the data passing between your organization and their service is encrypted and can't be sniffed. Most likely, the data will pass through the untrusted network connection that is the internet. Secure data transmission is critical.

Last, the cloud computing service provider should probe their system on a regular basis. They should contract with a third party whose expertise is breaking into systems. The third party should probe the cloud computing service to see if there are any weaknesses that can be exploited.

Cloud services are here to stay. No matter the organization you work for, they are probably going to use some type of cloud service. This is because cloud services are very cost-effective and convenient. However, with convenience comes risk. And it's your job as a security professional to identify those risk, account for them, and minimize them as much as possible.

10.4.4 Cloud Computing Facts

This lesson covers the following topics:

- Cloud computing
- Types of clouds

Cloud computing models

Cloud security risk reduction

Threat actors and attack surfaces

Virtual Desktop Infrastructure (VDI)

Cloud Computing

Cloud computing is software, data access, computation, and storage services provided to clients through the internet. The term *cloud* is a metaphor for the internet. It is based on the basic cloud drawing used to represent the telephone network. It is now used to describe the internet infrastructure in computer network diagrams. Characteristics of cloud computing include:

Delivery of common business applications that are accessed from a web service or software (like a web browser).

The cloud connection can exist over the internet or a LAN.

Cloud computing does not require end-user knowledge of the physical location and configuration of the system that delivers the services.

Types of clouds

Cloud computing can be implemented in several different ways, including the following:

Type	Description
Public cloud	A *public cloud* can be accessed by anyone. Cloud-based computing resources, such as platforms, applications, storage, or other resources, are made available to the general public by a cloud service provider. The service provider may or may not require a fee for using these resources. For example, Google provides many publicly accessible cloud applications, such as Gmail and Google Docs.
Private cloud	A *private cloud* provides resources to a single organization. Access is restricted to the users within the organization. Private clouds can be hosted internally. Because of the expense and expertise required to implement, clouds are typically hosted externally by a third party. An organization commonly enters into an agreement with a cloud service provider, which provides secure access to cloud-based resources. The organization's data is kept separate and secure from any other organization using the same service provider.
Community cloud	A *community cloud* is designed to be shared by several organizations. Access is restricted to users within the organizations who are sharing the community cloud infrastructure. Community clouds can be hosted internally or on-premise, with each organization sharing the cost of implementation and maintenance. Because of the expense and expertise required, community clouds are commonly hosted externally by a third party.
Hybrid cloud	A *hybrid cloud* is composed of a combination of public, private, and community cloud resources from different service providers. The goal behind a hybrid cloud is to expand the functionality of a given cloud service by integrating it with other cloud services.

The advantages of cloud computing are:

- Flexible access.
- Ease of use.
- Self-service resource provisioning.
- API availability.
- Service metering.
- The ability to try software applications in cloud computing service models.

Cloud Computing Models

Cloud computing service models include the following:

Model	Description
Infrastructure as a Service (IaaS)	IaaS delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments. The client deploys and runs software without purchasing servers, data center space, or network equipment.
Platform as a Service (PaaS)	PaaS delivers everything a developer needs to build an application. The deployment comes without the cost and complexity of buying and managing the underlying hardware and software layers.
Software as a Service (SaaS)	SaaS delivers software applications to the client over the internet or on a local area network. SaaS comes in two implementation types: Simple multi-tenancy in which each customer has its own resources that are segregated from other customers. Fine grain multi-tenancy segregates customers, but resources are shared.
Security as a Service (SECaaS)	SECaaS providers integrate their services into a corporate infrastructure. The applications and software are specific to organizational security. SECaaS is based on the Software-as-a-Service cloud computing model but is limited to information security services and does not require on-premises hardware. These security services can include authentication, anti-virus, anti-malware, spyware, intrusion detection, penetration testing, and security event management. SECaaS can sometimes be much more cost-effective for an organization than having to pay for all the necessary equipment and personnel to properly protect a network from viruses, malware, and instruction. However, it is still necessary to have an on-site security professional.

Cloud Security Risk Reduction

Cloud service providers reduce the risk of security breaches through the following actions.

- Authenticate all users who access the service and allow users to access only the applications and data that they need.
- Use a Cloud Access Security Broker (CASB). A CASB is a software tool or service that sits between an organization and a cloud service provider. Its job is to make sure that all communication and access to the cloud service provider complies with the organization's security policies and procedures.
- Segregate each organization's centrally stored data.
- Verify, test, and apply updates to the infrastructure.
- Establish a formal process for all facets of the service, from user requests to major data breaches and catastrophic events.
- Implement security monitoring for usage, unusual behavior, and other events.
- Implement encryption up to the point of use, such as the client's web browser.
- Probe for security holes with a third-party service provider.
- Comply with all regulatory measures, such as the Sarbanes-Oxley Act.

Threat Actors and Attack Surfaces

The attack surface is all the points at which a malicious threat actor could try to exploit a vulnerability. Any location or method where a threat actor can interact with a network port, app, computer, or user is part of a potential attack surface. Minimizing the attack surface means restricting access so that only a few known endpoints, protocols/ports, and services/methods are permitted. Each of these must be assessed for vulnerabilities and monitored for intrusions.

One potential threat to cloud services is what can be referred to as the supply chain. Because cloud services are used by organizations and other customers to create a number of possible end products and services, they can be considered a link in a supply chain. A supply chain is an end-to-end process of designing, manufacturing, and distributing goods and services to customers. Rather than attack the target directly, a threat actor may seek ways to infiltrate it via companies in its supply chain, such as an IaaS, PaaS, or SaaS.

The supply chain breadth and complexity expose organizations to a huge attack surface. For example, for a computer motherboard to be trustworthy, the supply chain of chip manufacturer, firmware code developer, OEM reseller, courier delivery company, and administrative staff responsible for provisioning the computing device to the end user must all be trustworthy. Anyone with the time and resources to modify the computer's firmware could create backdoor access. The same is true for any computer or network hardware, software, or service. This means that when employing companies offering cloud services, you must trust that their hardware, software, and services are secure.

Another important consideration regarding the supply chain is a Managed Services Provider (MSP). MSP provisions and supports IT resources such as networks, security, or web infrastructure. MSPs are useful when an organization finds it cheaper or more reliable to outsource all or part of IT provision rather than try to manage it directly. From a security point of view, this type of outsourcing is complex, as it can be difficult to monitor the MSP. The MSP's employees are all potential sources of insider threat.

Establishing a trusted supply chain for computer equipment and services essentially means denying malicious actors the time or resources to modify the assets supplied. For most businesses, using reputable vendors will represent the best practical effort at securing the supply chain. Government, military/security services, and large enterprises will exercise greater scrutiny. Particular care should be taken if using secondhand machines.

Virtual Desktop Infrastructure (VDI)

Cloud-based services can be hosted externally by third-party service providers or internally on your own virtualization infrastructure. For example, internal private clouds are commonly used to provide a VDI. Using VDI, user desktops are virtualized, running on high-end hardware in the data center instead of the end user's workstation hardware. The physical workstation is merely used to establish a remote connection to the user's virtualized desktop. This is sometimes called a *thin client* deployment because most of the computing power is provided by servers in the data center. Traditional deployments, where most of the processing load is handled by the local workstation, are called *thick client* deployments.

Using VDI provides increased flexibility, enhanced security, efficient management, and better data protection than the traditional workstation-based desktop model. Consider the following advantages:

- Workstation hardware costs are reduced. Only minimal workstation hardware is required to run a Remote Desktop (Windows) or VNC (Linux) client and connect to the private cloud.
- User data on the desktop can be protected centrally by backing up the hypervisors where the virtualized desktops are running. There is no need to back up physical workstations separately.
- If a user's physical workstation fails, no data is lost. The user can access the virtualized desktop from a different workstation while the failed hardware is repaired or replaced.
- If a widespread malware infection hits multiple user desktops, the affected virtual systems can be quickly re-imaged on the hypervisor. There is no need to push large images down to end users' workstations over the network.
- If a user loses a device, such as a notebook or tablet, there is much less of a chance that critical data will be compromised because no data is saved on the device.

10.4.5 Cloud Storage Security Facts

This lesson covers the following topics:

- Cloud storage
- Advantages of cloud storage

Cloud Storage

Cloud storage is a data storage model. It is usually provided by a third party as a service. Some of the most widely used cloud storage for enterprise providers are Google Cloud, Amazon Web Services, and Microsoft Azure. Many companies take advantage of cloud services to decrease costs and meet ever-increasing storage needs.

Cloud storage services may be accessed through a co-located cloud computer service, a web service application programming interface (API), or applications that utilize the API. Cloud desktop storage that uses a cloud storage gateway or web-based content management system is an example of an application that uses the API.

A cloud access security broker (CASB) may act as a gatekeeper, extending an organization's security policies into the cloud storage infrastructure. A CASB focuses on the visibility of the company data, regulation compliance, user access to prevent threats, and data security through encryption and loss prevention.

Cloud storage is:

- Made up of many distributed resources but still acts as one in a federated or cooperative storage cloud architecture.

Highly fault tolerant through redundancy and distribution of data.

Highly durable through the creation of versioned copies.

Cloud Storage is a virtual service; the infrastructure is the responsibility of the storage provider. Access controls should be set in the same way as a local file system would be set. There is no need for the provider to have access to the stored data. Measures for securing cloud storage include:

Implement security controls in the same way as in a physical datacenter.

Use data classification policies.

Assign information into categories that determine storage, handling, and access requirements.

Assign security classification based on information sensitivity and criticality.

Use specialized tools to dispose of data securely when it is no longer needed.

Advantages of Cloud Storage

The advantages of Cloud Storage are:

Companies pay only for the storage used. This does not necessarily mean that cloud storage is less expensive, but it incurs only operating expenses.

Cloud storage can cut energy consumption by up to 70%, making an organization more green.

Organizations can choose between off-premises and on-premises cloud storage options or a mixture of the two options.

Storage availability and data protection are intrinsic to object storage architecture. Depending on the application, you can eliminate the costs, effort, and additional technology to add availability and protection.

Storage maintenance tasks, such as purchasing additional storage capacity, are the responsibility of the service provider.

Cloud storage can be used to copy virtual machine images from the cloud to on-premises locations or import a virtual machine image from an on-premises location to the cloud image library.

Cloud storage can be used as natural disaster backup since cloud storage providers' backup servers are typically located in different places around the globe.

10.4.6 Analyze Infrastructure Types and Functions

10.4.7 Practice Questions (Section Quiz)

q_cloud_comp_characteristics_secp8

Which of the following is NOT a characteristic of cloud computing?

Answers:

Delivery of common business applications accessed from a web service or software.

The cloud connection can exist over the internet or a LAN.

***Cloud computing requires end-user knowledge of the physical location and configuration of the system that delivers the services.**

Cloud computing does not require end-user knowledge of the physical location and configuration of the system that delivers the services.

Explanation:

Cloud computing requires end-user knowledge of the physical location and configuration of the system that delivers the services is NOT a characteristic of cloud computing. One of the key features of cloud computing is that it abstracts the complexity and details of the system infrastructure from the end user. Users can access and use the services without needing to understand the underlying technology or infrastructure.

Delivery of common business applications accessed from a web service or software is a characteristic of cloud computing. Common business applications are delivered over the internet and can be accessed from a web service or software like a web browser.

The cloud connection can exist over the internet or a LAN is also a characteristic of cloud computing. The cloud connection can exist over the internet or a LAN (Local Area Network).

Cloud computing does not require end-user knowledge of the physical location and configuration of the system that delivers the services is a characteristic of cloud computing. Users do not need to know the physical location and configuration of the system that delivers the services.

q_cloud_comp_cloud_secp8

Match each description on the left with the appropriate cloud technology on the right.

Answers:

Provides cloud services to just about anyone.

Allows cloud services to be shared by several organizations.

Integrates one cloud service with other cloud services.

Provides cloud services to a single organization.

Explanation:

Cloud computing can be implemented in several different ways, including the following:

A public cloud can be accessed by anyone. Cloud-based computing resources are made available to the general public by a cloud service provider. The service provider may or may not require a fee for use of these resources. For example, Google provides many publicly accessible cloud applications, such as Gmail and Google Docs.

A private cloud provides resources to a single organization. Access is restricted to only the users within that organization. An organization commonly enters into an agreement with a cloud service provider, which provides

secure access to cloud-based resources. The organization's data is kept separate and secure from any other organization using the same service provider.

A community cloud is designed to be shared by several organizations. Access is restricted to only users within the organizations who are sharing the community cloud infrastructure. Community clouds are commonly hosted externally by a third party.

A hybrid cloud is composed of a combination of public, private, and community cloud resources from different service providers. The goal behind a hybrid cloud is to expand the functionality of a given cloud service by integrating it with other cloud services.

q_cloud_comp_community_secp8

A group of small local businesses have joined together to share access to a cloud-based payment system.

Which type of cloud is MOST likely being implemented?

Answers:

Hybrid

Public

Private

***Community**

Explanation:

A community cloud is designed to be shared by several organizations. Access is restricted to users within the organizations who are sharing the community cloud infrastructure.

A hybrid cloud is composed of a combination of public, private, and community cloud resources from different service providers.

A public cloud can be accessed by anyone.

A private cloud provides resources to a single organization.

q_cloud_comp_hybrid_secp8

A large organization is planning to move its operations to the cloud and is considering different cloud deployment models.

The organization wants to achieve a balance of cost, security, flexibility, and control over its data and applications and is considering a hybrid cloud model but has concerns about the security implications.

Which of the following is a potential security challenge the organization should consider when using a hybrid cloud model?

Answers:

***The organization may struggle with managing multiple cloud environments and enforcing consistent security policies.**

The organization will have no control over the security of its data and applications in the cloud.

The organization will have to bear the full cost of managing and securing the cloud infrastructure.

The hybrid cloud model is not scalable and may not be able to meet the organization's growing needs.

Explanation:

A hybrid cloud model can present security challenges, including the complexity of managing multiple cloud environments and enforcing consistent security policies across all environments.

In a hybrid cloud model, the organization can control the security of its data and applications in the private cloud infrastructure. However, it needs to ensure that the public cloud provider also has robust security measures.

In a hybrid cloud model, the organization would typically be responsible for securing the private cloud infrastructure, while the public cloud provider would be responsible for securing the public cloud infrastructure.

A hybrid cloud model allows the organization to use the private cloud for sensitive data and applications and use the public cloud for less sensitive, scalable workloads.

q_cloud_comp_iaas_secp8

A company is considering moving its applications and data to the cloud. The company handles sensitive data and wants to maintain control over the security of its applications and data.

It is considering using an infrastructure as a service (IaaS) model.

Which of the following is a key responsibility the company will need to manage in an IaaS model?

Answers:

Securing foundational elements of networking, such as DDoS protection

Physical security of the cloud infrastructure

***Protection of operating systems when deployed**

Cloud storage backup and recovery

Explanation:

In an IaaS model, the customer is responsible for protecting the operating systems it deploys on the cloud infrastructure. This includes tasks like applying security updates and patches, managing access controls, and implementing intrusion detection systems.

In an IaaS model, the cloud service provider is typically responsible for securing foundational elements of networking, including distributed denial of service (DDoS) protection.

The cloud service provider, not the customer, typically manages the physical security of the cloud infrastructure.

While customers must manage their data and backups, the cloud service provider typically provides and manages the infrastructure for cloud storage backup and recovery.

q_cloud_comp_paas_secp8

Which of the following BEST describes the platform as a service (PaaS) cloud computing service model?

Answers:

***PaaS delivers everything a developer needs to build an application on the cloud infrastructure.**

PaaS delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments.

PaaS delivers software applications to the client either over the internet or on a local area network (LAN).

PaaS stores and provides data from a centralized location without the need for local collection and storage.

Explanation:

Platform as a service (PaaS) delivers everything a developer needs to build an application on the cloud infrastructure. The deployment comes without the cost and complexity of buying and managing the underlying hardware and software layers.

Software as a service (SaaS) delivers software applications to the client either over the internet or on a local area network. Infrastructure as a service (IaaS) delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments. The client deploys and runs software without purchasing servers, data center space, or network equipment. Data as a service (DaaS) stores and provides data from a centralized location without the need for local collection and storage.

q_cloud_comp_risk_reduction_secp8

You are the CISO of a large organization that is transitioning to cloud services. One of your main concerns is ensuring the security of your organization's data in the cloud.

Which of the following actions would be the LEAST effective in reducing cloud security risks?

Answers:

Implementing a Cloud Access Security Broker (CASB) to ensure all communication and access to the cloud service provider complies with the organization's security policies and procedures.

Segregating each organization's centrally-stored data.

***Regularly updating the organization's social media accounts with information about the transition to the cloud.**

Establishing a formal process for all facets of the service, from user requests to major data breaches and catastrophic events.

Explanation:

Regularly updating the organization's social media accounts with information about the transition to the cloud would be the LEAST effective measure. While transparency is important, regularly updating social media accounts with information about the transition to the cloud does not directly contribute to reducing cloud security risks. In fact, it could potentially provide threat actors with information they could use to target the organization.

A CASB is a software tool or service that sits between an organization and a cloud service provider to ensure all communication and access complies with the organization's security policies and procedures.

Segregating each organization's centrally-stored data can help prevent unauthorized access and data breaches.

Establishing a formal process for all facets of the service can help ensure that potential security issues are addressed promptly and effectively, reducing the risk of data breaches and other security incidents.

q_cloud_comp_saas_01_secp8

Which of the following cloud computing solutions delivers software applications to a client either over the internet or on a local area network?

Answers:

IaaS

PaaS

***SaaS**

DaaS

Explanation:

Software as a service (SaaS) delivers software applications to the client either over the internet or on a local area network (LAN).

Infrastructure as a service (IaaS) delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments. The client deploys and runs software without purchasing servers, data center space, or network equipment.

Platform as a service (PaaS) delivers everything a developer needs to build an application on the cloud infrastructure. The deployment comes without the cost and complexity of buying and managing the underlying hardware and software layers.

Data as a service (DaaS) stores and provides data from a centralized location without the need for local collection and storage.

q_cloud_comp_saas_02_secp8

A rock band wishes to set up a system for communicating with their fans upon arrival at concerts and providing them with relevant hashtags for participation.

Which type of cloud service model would be MOST beneficial to recommend to the rock band?

Answers:

***Software as a service (SaaS)**

Platform as a service (PaaS)

Infrastructure as a service (IaaS)

Third-party vendor

Explanation:

The software as a service (SaaS) model would be the most appropriate recommendation, enabling the band to use preconfigured applications for sending text messages. It also manages fan engagement without extensive development or infrastructure setup.

Platform as a service (PaaS) provides resources and platforms for developing software applications. However, the band does not need to develop its software in this scenario.

Infrastructure as a service (IaaS) allows for provisioning IT resources such as servers, load balancers, and storage components. However, this is unnecessary as the band does not require infrastructure.

A third-party vendor refers to providers offering cloud services. While this type of vendor can be part of the solution, it is not a service model.

q_cloud_comp_secaas_secp8

You are the security administrator for your organization. You have implemented a cloud service to provide features such as authentication, anti-malware, intrusion detection, and penetration testing.

Which cloud service have you MOST likely implemented?

Answers:

IaaS

***SECaaS**

PaaS

SaaS

Explanation:

Security as a service (SECaaS) providers integrate their services into a corporate infrastructure. The applications and software are specific to organizational security. SECaaS is based on the software as a service (SaaS) cloud computing model. However, it is limited to information security services and does not require on-premises hardware. These security services can include authentication, antivirus, anti-malware, spyware, intrusion detection, penetration testing, and security event management.

IaaS delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments.

PaaS delivers everything a developer needs to build an application.

SaaS delivers software applications to the client over the internet or on a local area network.

q_cloud_comp_supply_chain_secp8

A recent attack on a major retail chain resulted in stolen customer private information, including credit card information.

The report explained that a heating, ventilation, and air conditioning (HVAC) contractor copied the information to an external hard drive while servicing an air conditioner unit and later uploaded the data to a cloud storage resource.

A security engineer would classify this type of attack as which of the following?

Answers:

***Supply chain attack**

Cloud-based attack

Birthday attack

USB cable attack

Explanation:

A supply chain attack involves a threat actor seeking methods to infiltrate a company in its supply chain. An HVAC supplier is one example of using a maintenance service to gain access to sensitive areas like a data center.

A cloud-based attack involves a threat actor compromising one account with access to cloud resources to compromise other cloud assets further.

A birthday attack is a brute-force attack aimed at exploiting collisions in hash functions.

A Universal Serial Bus (USB) cable attack involves accessing unsuspecting users after they try to plug their devices into malicious USB cables or plugs, similar to card skimmers.

q_cloud_comp_thin_secp8

The IT manager has tasked you with installing new physical machines. These computer systems are barebone systems that simply establish a remote connection to the data center to run the user's virtualized desktop.

Which type of deployment model is being used?

Answers:

***Thin client**

IaaS

PaaS

Thick client

Explanation:

This type of deployment is often referred to as a thin client deployment. This deployment utilizes virtual desktop infrastructure (VDI) to virtualize a user's desktop. The client machine is essentially only used to connect to the high-end machines in the data center.

IaaS delivers infrastructure to the client, such as processing, storage, networks, and virtualized environments.

PaaS delivers everything a developer needs to build an application.

Traditional deployments, where most of the processing load is handled by the local workstation, are called thick client deployments.

q_cloud_comp_vdi_secp8

Which of the following are true concerning virtual desktop infrastructure (VDI)? (Select two.)

Answers:

***User desktop environments are centrally hosted on servers instead of on individual desktop systems.**

User desktop environments are provided by individual desktop systems instead of by remote servers.

***In the event of a widespread malware infection, the administrator can quickly reimage all user desktops on a few central servers.**

In the event of a widespread malware infection, the administrator can reimage user desktops by pushing an image out to each user desktop system over the network.

Roaming profiles must be configured to allow mobile users to keep their same desktop environment across systems.

Explanation:

Virtual desktop infrastructure (VDI) is a service that hosts user desktop environments on centralized servers. Users access their desktops from low-end systems over a network connection using a remote display protocol such as Remote Desktop or Virtual Network Computing (VNC). This allows users to access their desktop environment with their applications and data from any location and from any client device. Roaming profiles are not needed.

VDI provides administrators with a centralized client environment that is easier and more efficient to manage. For example, if a widespread malware infection hits multiple user desktops, the affected systems can be quickly reimaged on the VDI server. There is no need to push large images down to client systems over the network.

q_cloud_stor_available_secp8

Google Cloud, Amazon Web Services (AWS), and Microsoft Azure are some of the most widely used cloud storage solutions for enterprises.

Which of the following factors prompt most companies to take advantage of cloud storage? (Select two.)

Answers:

***Growing demand for storage**

***Need to bring costs down**

Need for a storage provider to manage access control

Need for platform as a service (PaaS) for developing applications

Need for software as a service (SaaS) for managing enterprise applications

Explanation:

Some of the most widely used cloud storage for enterprises are Google Cloud, Amazon Web Services, and Microsoft Azure. Because of the growing demand for storage and desire to bring costs down, many companies have been taking advantage of cloud storage.

The majority of companies prefer to manage access control to data in the cloud in order instead of turning over this critical responsibility to a third-party, such as a storage provider.

While PaaS and SaaS are types of cloud environments that provide tools and applications for developing applications or managing enterprise applications, most companies want to reserve access control to the data stored on these platforms in order to maintain a high level of security.

q_cloud_stor_casb_secp8

Which of the following cloud storage access services acts as a gatekeeper, extending an organization's security policies into the cloud storage infrastructure?

Answers:

***A cloud-access security broker**

A web service application programming interface

A co-located cloud computer service

A cloud storage gateway

Explanation:

A cloud-access security broker (CASB) may act as a gatekeeper, extending an organization's security policies into the cloud storage infrastructure. A CASB focuses on the visibility of company data, regulation compliance, user access, and data security through encryption and loss prevention.

Cloud storage services may be accessed through a co-located cloud computer service, a web service application programming interface (API), or by applications that utilize the API, such as cloud desktop storage (in other words, cloud storage gateways or web-based content management systems).

q_cloud_stor_casb_sol_secp8

A large multinational corporation is planning to move a significant portion of their data storage to the cloud.

As the company's lead cybersecurity analyst, you are tasked with ensuring the security of the company's data during and after the transition.

Which of the following would be the most effective solution to extend the company's security policies into the cloud storage infrastructure, provide visibility of the company data, ensure regulation compliance, prevent threats through user access control, and secure data through encryption and loss prevention?

Answers:

Implementing a robust firewall system

***Using a Cloud Access Security Broker (CASB)**

Regularly updating antivirus software

Conducting frequent penetration testing

Explanation:

Using a Cloud Access Security Broker (CASB) is the correct answer. A CASB acts as a gatekeeper, extending an organization's security policies into the cloud storage infrastructure. It provides visibility of the company data, ensures regulation compliance, controls user access to prevent threats, and secures data through encryption and loss prevention.

While a firewall is an essential part of any security infrastructure, it primarily protects the network from unauthorized external access. It does not extend an organization's security policies into the cloud or provide visibility of the company data in the cloud.

While regularly updating antivirus software is a good practice for protecting against malware, it does not specifically address the security needs of cloud storage.

Penetration testing is a valuable tool for identifying vulnerabilities in a system. However, it does not provide the continuous monitoring and policy enforcement that a CASB does.

q_cloud_stor_cloud_secp8

Cloud storage is a virtual service, so the infrastructure is the responsibility of the storage provider. Access control should be set as a local file system would be, with no need for the provider to have access to the stored data.

You are implementing the following measures to secure your cloud storage:

Verify that security controls are the same as in a physical data center.

Use data classification policies.

Assign information into categories that determine storage, handling, and access requirements.

Assign information classification based on information sensitivity and criticality.

Which of the following is another security measure you can implement?

Answers:

***Dispose of data when it is no longer needed by using specialized tools.**

Create versioned copies of your cloud data.

Configure redundancy and distribution of data.

Configure distributed resources to act as one in a federated architecture.

Explanation:

Disposing of data when it is no longer needed by using specialized tools is another security measure you can implement.

Creating versioned copies of your cloud data, configuring redundancy and distribution of data, and configuring distributed resources to act as one in a federated architecture are all measures that improve the fault tolerance and durability of your data.

q_cloud_stor_risk_secp8

A tech company plans to launch a new application on a cloud platform to cater to its growing customer base. The lead security analyst examines potential vulnerabilities to ensure the application remains secure after deployment.

The analyst focuses on potential weak points within the application's design and the cloud platform's infrastructure.

Considering vulnerabilities associated with applications and cloud platforms, which of the following issues poses the highest risk related to unauthorized data access in cloud-hosted applications?

Answers:

Inefficiently allocated cloud resources

Disabled logging features within the application

***Misconfigured cloud storage access controls**

Absence of multi-factor authentication (MFA) for application users

Explanation:

Misconfigured access controls on cloud storage can allow unauthorized users to access, modify, or delete data. Misconfigured access controls pose a direct threat to data integrity and confidentiality.

While inefficient resource allocation can lead to performance issues and increased costs, it does not directly correlate with unauthorized data access.

While logs are crucial for monitoring and detecting malicious activities, their absence primarily hampers post-incident investigations rather than directly causing unauthorized data access.

While MFA provides an added layer of security, its absence primarily affects user account security. However, a misconfigured cloud storage can allow unauthorized data access even with MFA.

10.5 Mobile Devices

As you study this section, answer the following questions:

Which process allows you to define specific apps that users can have on mobile devices?

Which two configurations can be used to deploy Windows Intune?

What does a mobile device management (MDM) solution allow you to do?

How do jailbreaking and sideloading differ?

In this section, you will learn to:

Enforce security policies on mobile devices.

Sideload an application.

The key terms for this section include:

Term	Definition
App whitelisting	The process of identifying apps that users are allowed to have on mobile devices.
Geotagging	The process of embedding GPS coordinates within mobile device files, such as image or video files created with the device's camera.
Data exfiltration	The unauthorized copy, transfer, or retrieval of data from a computer, server, or network.
Sandboxing	The isolation of an app so that it can't affect other areas of a computer or network.
Jailbreaking	The process of removing inherent protections placed by the device manufacturer.
Sideloading	Installing an app on a mobile device via a method other than the manufacturer's app repository.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
TestOut Security Pro	2.2 Harden network devices 2.2.6 Bring Your Own Device (BYOD) security
CompTIA Security+ SY0-701	2.3 Explain various types of vulnerabilities. Mobile device Side loading Jailbreaking 2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Application allow list Hardening techniques Encryption

3.3 Compare and contrast concepts and strategies to protect data

- Methods to secure data
  - Encryption

4.1 Given a scenario, apply common security techniques to computing resources.

- Secure baselines
  - Establish
  - Deploy
- Hardening targets
  - Mobile devices
- Wireless devices
  - Installation considerations
- Mobile solutions
  - Mobile device management (MDM)
  - Deployment models
    - Bring your own device (BYOD)
    - Corporate-owned, personally enabled (COPE)
    - Choose your own device (CYOD)
  - Connection methods
    - Cellular
    - Wi-Fi
    - Bluetooth
  - Application security
    - Code signing
  - Sandboxing

4.5 Given a scenario, modify enterprise capabilities to enhance security.

	Operating system security Group Policy 4.6 Given a scenario, implement and maintain identity and access management. Password concepts Password managers

10.5.1 Mobile Device Connection Methods (Lesson Video)

Transcript:

Mobile devices pose a unique threat to modern networks. The days when you only had to worry about static workstations that sit in a cubicle are gone. Instead, security professionals also have to worry about countless mobile devices that can be brought in and out of office and are subject to a host of security vulnerabilities.

In this lesson, we're going to take a look at some considerations you need to keep in mind when it comes to mobile devices and the threats they pose to a network.
Let's first take a look at the various connection methods used by mobile devices. Mobile devices use a variety of ways to connect to the internet, the network, and even other devices.
You're probably familiar with cellular and Wi-Fi connections. This is something practically all mobile devices are equipped with. However, mobile devices can also use Bluetooth, NFC, ANT, and infrared to communicate wirelessly.
And each of these connection methods have their own set of security concerns you should be aware of.
For example, Bluetooth is susceptible to Bluejacking and Bluesnarfing, and NFC is susceptible to relay attacks, data corruption, and eavesdropping. So, when implementing mobile devices, be sure to account for the various vulnerabilities each of these connection methods have.
One way to protect against these is to simply disable these connection methods when they aren't being used. This is probably the best way to protect against attacks that leverage vulnerabilities in these systems.
Another way to secure mobile device communications is to employ proper security settings and ensure the use of security protocols. For example, make sure to only allow connections with trusted devices.
Another thing to consider with mobile devices is that of geolocation settings.
Most mobile devices are equipped with GPS, allowing them to use geolocation services. This helps with certain apps, such as maps and weather applications. However, you can also use the GPS unit in mobile devices for security purposes.
For example, using a technique called geofencing, you can lock mobile devices to a particular geographical area. You specify a geographic area where the mobile device is allowed to function a virtual boundary of sorts. If the mobile device moves outside of that area, it can either instruct the user to move back into that area, or even lock the user out from accessing the device altogether.
This functionality can be useful if you issue mobile devices to employees, but don't want them to be able to take them home to use.
Geofencing can also be used to trigger alerts or notifications. For example, it can be used to remind a user to carry out a particular task when they reach a geographic location.
Geolocation services can be of great value to mobile devices, but they also create some security concerns. One of these concerns is that of geolocation data embedded in images.
See, when someone takes a photo on their phone or mobile device, the geographic location where that photo was taken is embedded in the image's EXIF data. If the user was to upload this photo to the internet, a malicious individual could use the EXIF data to carry out a social engineering attack.

To combat this, be sure to disable geotagging on mobile devices.
Another concern with mobile devices is the fact that they are mobile. Because users are able to take them home, to the coffee shop, to wherever, they have the added risk of being lost or stolen. And if that device contains sensitive information or company documents, you risk compromising that information.
To protect against this threat, you can do a couple of things. First, you can employ full device encryption on all mobile devices and require them to have some type of screen lock and authentication method, whether it's a pin, password, biometric, whatever. Just make sure the device requires authentication for access.
Another thing you can do is require all mobile devices to have some type of remote wipe feature. Most mobile devices have built-in remote wipe features, but you might also have to install a third-party remote wipe feature if necessary.
And lastly, mobile devices pose a risk for organizations in the form of data exfiltration.
For example, a disgruntled employee could use their phone to take photos of sensitive information or transfer documents to their phone via Wi-Fi, Bluetooth, or USB. They could even use the device to record sensitive conversations.
If this is a concern for your organization, consider having an extremely strict mobile device policy or only allow the use of company-owned mobile devices on the premises.
Mobile devices pose a unique threat to an organization. And mobile device use is only going to increase in the future. Because of this, it's important that you understand the threats that mobile devices pose to an organization and the steps you can take to properly protect your network.

10.5.2 Mobile Device Connection Facts

Whether it is a tablet, smartphone, or e-reader, all mobile devices share some common characteristics.

This lesson covers the following topics:

- Connection types
- Security considerations
- Application management
- Apps security issues

Connection Types

Mobile devices can use various methods to connect to the internet, network, and other devices. Connection methods include:

- Cellular
- WiFi
- Bluetooth
- NFC
- ANT
- Infrared
- USB
- SATCOM (satellite)

Security Considerations

Mobile device security considerations include:

- Device content management.
- Remote wipe.
- The ability to restrict the device to a particular geographical area (geofencing).
- The ability to manage location information (known as geolocation).
- The requirement to lock the screen with passwords.
- The management of push notification services that can send messages and information to the device when the screen is locked, and the application is not active.
- The ability to store and manage passwords for networks, websites, etc.
- Biometrics.
- Full device encryption.

Application Management

Security considerations regarding the management of applications on the mobile devices include:

- Rooting/jailbreaking/sideloading to load apps from third-party app stores or other websites.
- Flashing with custom firmware.
- Carrier unlocking. This is the ability to use different mobile carrier networks.
- The ability to receive over-the-air (OTA) firmware updates and app updates.
- Camera usage and geolocation information in pictures.
- Text and multimedia message protocols (SMS/MMS).
- Connection to external media.
- Connection using USB OTG (on-the-go).
- The use of a microphone for recording purposes.
- *Tethering* . This is the ability to share internet connectivity with other devices.

Apps Security Issues

When working with mobile device apps, be aware of the following security issues:

Security Issue	Implementation
App control	Application control is implemented in a similar manner for most mobile device operating systems. For iOS devices, all apps come from Apple's App Store, which uses the following mechanisms to secure apps: Running apps are sandboxed. This means they cannot access data stored by other running apps, nor can they access system files and resources. All iOS apps must be digitally signed by Apple or by a third-party developer using an Apple-issued certificate. This ensures that apps from the App Store haven't been tampered with. App developers can use encryption APIs to protect app data. Data can be symmetrically encrypted using AES, RC4, or 3DES. For Windows RT devices, all apps come from Microsoft's Windows Store. The following mechanisms secure apps: Windows RT refuses to load modules not digitally signed by Microsoft. This ensures that apps from the Windows Store have not been tampered with. All apps available through the Windows Store use the Windows RT API, which contains significant security enhancements, including: Windows anti-buffer-overflow memory restrictions Data Execution Prevention (DEP) Address Space Layout Randomization (ASLR) SafeSEH, sacrificial canary values Be aware, however, that iOS devices can be jailbroken. *Jailbreaking* allows apps to be installed from sources other than the App Store. Likewise, apps that aren't from the Windows Store can be installed on Windows RT devices using a process called *sideloading* . Either of these actions can seriously compromise the security of the device and should be avoided. Apps for the Android operating system are not as tightly controlled as those for iOS and Windows RT. Some Android app stores implement good security and tightly controlled apps, much like the App Store and the Windows Store, but others do not. It is strongly recommended that you use apps that come only from a reputable source, such as the following: Google Play Store Amazon Appstore for Android

	Samsung Apps
Authentication and credential management	The average end user must remember passwords for various network resources and services, including web-based services. To make life easier, the credential management function implemented in most mobile operating systems can store usernames and passwords for the end user. A good example is Credential Manager in Windows RT. The iOS operating system performs a similar function using an encrypted keychain for storing digital identities, usernames, and passwords. When the user accesses a password-protected network resource or website, the credential management software supplies the necessary username and password, effectively allowing the user to log in automatically. While credential management software is convenient for the end user, it can also represent a security risk. For example, suppose a user has stored credentials to a sensitive network resource or website on a mobile device and then loses that device. If the user fails to secure the device with a password or PIN, a malicious individual could exploit the stored credentials to gain unauthorized access. It is recommended that you train users not to store credentials to sensitive network resources on their mobile devices.
App whitelisting	App whitelisting is the process of defining specific apps that users can have on their mobile devices. For example, Windows RT provides a feature named Assigned Access, which allows you to define a whitelist of Windows Store applications. Assigned Access ensures that the device has installed only the apps required for its intended purpose. Apps that aren't on the whitelist are not allowed. For iOS and Android devices, app whitelists can be defined and enforced using a mobile device management (MDM) solution.
Geo-tagging	Geo-tagging embeds GPS coordinates within mobile device files, such as image or video files created with the device's camera. While this feature can be useful in some circumstances, it can also create security concerns. For example, if a user regularly posts geo-tagged images to a social media site, cybercriminals could analyze the images and quickly discover where the user works, even the cubicle location. The attacker could possibly derive the user's work hours and personal habits, such as restaurants the user visits for lunch. All of this information could be compiled and used for social engineering attacks on the organization. As a consequence, it is recommended that this functionality be disabled on mobile devices you manage.

10.5.3 Enforcing Mobile Device Security (Lesson Video)

Transcript:

Let's look at mobile device application security.

You need to be aware of several key security issues related to mobile device apps. These issues include making sure that the apps haven't been tampered with, that they don't contain malware, and that they're not sending information to other parties without approval.

The first issue we're going to look at is application control. Let's start by looking at iOS devices.

All apps on iOS devices come from Apple's app store. The Apple app store uses several different mechanisms to secure those apps. One mechanism is sandboxing. A sandboxed app cannot access data stored by other apps running on the device. They cannot access system files or system resources.

In addition, all iOS apps are digitally signed by Apple or a third-party developer. The digital signature uses an Apple-issued certificate and ensures that the apps from the app store haven't been tampered with. App developers can use encryption APIs to protect their app's data. Developers can use symmetric encryption, generated using AES, RC4, or Triple DES.

For Windows mobile devices, all apps come from the Windows store. Like iOS apps, Windows Store apps are digitally signed by Microsoft before they can be loaded on Windows mobile devices. Again, this ensures that the apps from the Windows store haven't been tampered with.

All apps available through the Windows store use the Windows RTAPI, which contains significant security enhancements, such as anti-buffer overflow memory restrictions, data execution prevention (DEP), address space layout randomization, Safe Structured Exception Handling (SafeSEH), and sacrificial canary values.

The Android operating system is based on the Linux kernel and is released through open source licenses.

Some Android stores implement good security and tightly control their apps, much like the App store and the Windows store do. However, other Android app stores do not. If your users have devices with the Android operating system, it is strongly recommended that you require them to use apps that come from a reputable source, such as Google Play Store, Amazon App Store for Android, and Samsung Apps.

Now, even though Apple, Microsoft, and Android control which apps are installed on their devices, it is possible to circumvent these protections by either jailbreaking the device or sideloading an app.

Jailbreaking a device is the process of removing inherent protections placed by the device manufacturer. In the case of an Apple or Android phone, the operating system can be jailbroken in order to allow the installation of non-Apple store apps or to gain elevated root privileges.

In addition, Windows and Android phones are susceptible to app sideloading. With Windows devices, this is when non-Windows store apps are installed on the Windows device. These apps have not been signed by Microsoft and could contain malware. With Android devices, you sideload by installing an application via an APK that was downloaded from the internet.

Authentication and credential management are also key issues with mobile devices.

The average user has to remember usernames and passwords for a variety of network resources and services, including web-based resources. To make life easier, many mobile device operating systems implement some type of credential management system that automatically stores user names and passwords for the user.

When a user accesses a password-protected network resource or website the first time, credential management stores the credentials for that resource. When the user accesses that same resource again, the credential management software automatically supplies the necessary user name and password. This allows the user to automatically log in to that resource. Windows RT has a credential manager. iOS also has a similar function that uses an encrypted key chain for storing digital identities, usernames, and passwords. Android devices can use the Google ecosystem or a third-party app.

Using credential management software is really convenient for the user. From a security standpoint, it presents risks. For example, suppose a user has stored credentials to a sensitive network resource or website on their mobile device, and they lose that device. Any individual who finds the device could exploit that information to gain unauthorized access, especially if the user failed to secure the device with a password or pin number.

Therefore, as a best practice, train your users not to store credentials to sensitive network resources on their mobile devices.

App whitelisting is another mobile device application security consideration. App whitelisting defines specific apps a user can install on a mobile device.

Windows RT provides a feature called Assigned Access. Assigned Access allows you to define a list of allowed Windows Store applications. The mobile device can only have the specified apps installed. For example, the mobile device could be a point of sales system or an educational device. For those purposes, you don't want Angry Birds installed on the device. Any app that's not found on the whitelist is not allowed on the device.

On iOS and Android devices, you can use a Mobile Device Management, MDM, solution to define and enforce an application whitelist. You can use an MDM solution, such as Windows Intune, to provide application whitelisting for Windows RT devices.

Another key issue related to mobile device apps is geolocation data. Geolocation embeds GPS coordinates within mobile device files, such as an image or video file, created with the device's camera.
If geolocation is enabled, the device's GPS location at the time the file is created is embedded within the device files. This includes all pictures taken, such as those on your vacation, with co-workers at lunch, or in your cubicle.
This feature can be useful in some circumstances, but it can also create security concerns. If these pictures or videos are posted on the internet, an attacker can obtain information about you that you don't want them to have.
For example, let's say a user in your organization regularly posts images with geolocation embedded to a social media site like Facebook. A cybercriminal could analyze these images and quickly discover information, such as where the user works, who they work for, and where the user's cubicle is located. A cybercriminal could even derive the user's work hours, work projects, and personal work habits, such as the restaurant they go to for lunch.
All of this information can be compiled and used for social engineering attacks against the organization. Therefore, it is best practice to require that users disable the geolocation setting for mobile devices.
In this lesson, we talked about mobile device application issues. We first talked about making sure you get apps from a reputable source. We talked about credential management and authentication. We looked at application whitelisting. Then we ended this lesson by talking about geotagging.

10.5.4 Enforcing Mobile Device Security Facts

One of the key problems associated with managing mobile devices is the fact that they cannot be joined to a Windows domain. This means Group Policy cannot be used to push security settings to mobile devices automatically.

This lesson covers the following topics:

- Mobile Device Management (MDM)
- Windows Intune
- Windows Intune configurations
- System configuration for Windows Intune

Mobile Device Management (MDM)

One option you can use instead of Group Policy is Mobile Device Management (MDM). Its security settings include the following:

- Security settings can be manually configured on each device. This option doesn't require any additional infrastructure to be implemented. However, it can be a time-consuming task for the administrator (especially in a large organization with many mobile devices) and is not recommended.
- For devices running Apple's iOS operating system, security settings can be distributed in a configuration profile for users to install. The profile can be defined so that only an administrator can delete the profile, or you can lock the profile to the device so that it cannot be removed without completely erasing the device. This option also doesn't require any additional infrastructure for implementation. However, it does rely on the end user to implement the profile, which can be problematic. Additionally, it is not a dynamic strategy, so making even the smallest change to your Mobile Device Security policies would require a great deal of effort to implement.
- A Mobile Device Management solution that pushes security policies directly to each device over a network connection can be implemented. This option enables policies to be remotely enforced and updated without any action by the end user. Many companies have MDM products, including Apple, Cisco, and Microsoft.

Windows Intune

One widely used MDM solution is Windows Intune, which provides cloud-based Mobile Device Management that allows you to remotely manage and secure mobile devices (as well as standard desktop systems starting with Windows 7 or later). Intune cannot be used to manage Windows Server.
The table below shows which operating systems Windows Intune currently supports:

Device	Supported
Apple	Apple iOS 8.0 and later Mac OS X 10.9 and later
Windows	Windows 10 (Home, S, Pro, Education, and Enterprise versions) Windows 10 Mobile Windows Phone 8.1 Windows 8.1 RT PCs running Windows 8.1 Devices running Windows 10 IoT Enterprise (x86, x64) Devices running Windows 10 IoT Mobile Enterprise Windows Holographic & Windows Holographic Enterprise
Google	Google Android 4.0 Google Android for Work

Customers with Enterprise Management + Security (EMS) can also use Azure Active Directory (Azure AD) to register Windows 10 devices.

Windows Intune Configurations

Windows Intune can be deployed in two different configurations:

- Intune Standalone is the recommended deployment method. Intune Standalone is a cloud-only solution that is managed using a web console that can be accessed from anywhere with internet access.
- Hybrid MDM with Configuration Manager is a solution that combines Intune's Mobile Device Management capabilities into Configuration Manager. It uses Intune for policies, profiles, and applications for devices, but it uses Configuration Manager to administer content and manage the devices.

This course covers only cloud-only deployments. Deploying Intune in United Configuration Mode requires experience and skill beyond the scope of this course.

You must first sign up for an account at Microsoft's website before you can use Intune. After you sign up for an Intune account, you can manage the deployment using the following Intune Management Portals:

Account Portal (https://account.manage.microsoft.com) is used to manage subscriptions, users, groups, and domains. End users can also use the account portal to manage their passwords.

Admin Portal (https://admin.manage.microsoft.com) is used to manage enrolled devices and policies.

Company Portal (https://portal.manage.microsoft.com) is used by end users to manage their own accounts and enroll devices.

System Configuration for Windows Intune

After signing up for a Windows Intune subscription, you need to configure the system by completing the tasks listed in the table below:

Configuration Task	Description
Add Intune users	Windows Intune uses administrative and standard users. The first user account created when you sign up for an Intune subscription is made an administrator by default. Additional standard users can be created and managed using the account console by selecting **Management** > **Users** > **New** > **User** . You can also synchronize users and groups into the account console from your Active Directory domain.
Define Intune policies	Intune policies allow you to manage your mobile devices. You can perform tasks such as: Configuring security settings. Applying updates. Configuring firewall settings. Policy settings can be applied to both standalone and domain-joined devices. However, policy conflicts can occur with domain-joined devices. To prevent this from happening, verify that domain-joined devices are not configured to receive the same configuration settings from both Active Directory Group Policies and Windows Intune. Intune provides the following policy templates containing recommended settings that you can deploy: Mobile Device Security Policy Windows Firewall settings Windows Intune Agent settings

	Windows Intune Center settings To set up your Intune policies, access the admin console and select **Policy** > **Add Policy** . Select the policy you wish to deploy and select **Create and Deploy a Policy** . At a minimum, it is recommended that you deploy all of the above policies using the default settings and apply them to either all devices or all users. If necessary, you can later modify the default settings in the policy. You can also configure specific devices or users that a policy applies to.
Manage users and groups	Windows Intune uses two types of groups: User groups allow you to deploy software and Mobile Device Security policies to specific user accounts. Device groups allow you to deploy software, Intune agent settings, and firewall settings to specific devices. To add groups using the Account Console, select Admin > Security Groups > New > **Group** .
Enroll computers	You can enroll standard computer systems (desktops and notebooks) in Windows Intune in one of two ways: Administrator enrollment requires an Intune administrator to set up the enrollment for a specific user. User enrollment allows a user to enroll a computer through the Company Portal. Before you can enroll a system in Intune, you must first download and install the Intune client software on the computer. To do this using administrator enrollment, complete the following: Open a browser and access the Admin Console. Select Administration > Client Software Download > **Download Client Software** . Once this zip file has been downloaded, extract its contents and run the **Windows_Intune_Setup.exe** file as an administrator user. After the installation is complete, restart the computer. The newly managed computer should appear in the Intune Admin Console after a few minutes. Administrator-enrolled computers must be manually linked to an Intune user ID. In the Admin Console, go to Groups > All Devices; then select the device and **Link User** . Users can self-enroll a computer by opening a browser, accessing the company portal, and logging in using their Intune user ID. Then, they select the option to enroll the current device. User-enrolled devices are automatically linked to the user ID that enrolled them.
Enroll mobile devices	To enroll mobile devices in Intune, you must first enable Mobile Device Management in the Admin Console. Select the Administration workspace; then select Mobile Device Management > **Set Mobile Device Management Authority** > **Yes** .

	Users must configure mobile devices with the address of the Intune enrollment server (enterpriseenrollment-s.manage.microsoft.com) during the enrollment process. Be sure users are provided with this address prior to starting the device enrollment process. At this point, Windows RT mobile devices can be enrolled with Windows Intune. To enroll a Windows RT device, search for and run **Company Apps** , then enter your Intune user ID and password along with the address of the enrollment server. Once enrolled, select the link displayed to install the management app from the Windows store. If you want to enroll other types of mobile devices, you must configure Intune for each platform you plan to support. For example, if you want to manage iOS devices, you must obtain an Apple Push Notification service (APNs) certificate and then upload it to Intune. Alternatively, if you plan to support Windows Phone 8 devices, you must get a Windows Phone Dev Center account and upload a signed enterprise mobile code certificate to Intune.

10.5.5 Enforcing Security Policies on Mobile Devices (Demo Video)

Transcript:

There are a lot of things you can do to secure your infrastructure. This is thanks to Microsoft's Intune. In this demonstration, we'll take some steps to secure our environment with Intune. We're going to take a look at Intune security policies, specifically some nice baselines that we're provided with that can really assist us in this manner.

So, what we do is search All Services here and do a search on baselines. This brings us to security baselines. There are these great Microsoft security baselines that we can call on to enact good, secure practices inside of our enterprise. These baselines include some basic security settings that we want to consider.
For example, there's a Microsoft Edge baseline here. We can go ahead and incorporate this into the security posture of our environment. Thanks to Profiles, we can link it in. So let's go ahead and take a look at that. Under Profiles, notice there are no profiles set up for this baseline. But we can easily change that. We'll go in and say this is my Edge profile. We could give it a description if we wanted to. It's automatically limited to Windows 10 and later. As of October 2019, that's Edge version 77 and later. So we'll say Next. Edge has a lot of settings. The defaults are to enable the supported authentication schemes and then list which ones those are. We can set those.
There's the Adobe Flash settings, extension controls, and the ability to save passwords in the software built into Edge. We have many security settings. Notice they're preset a certain way to give a good baseline of security when it comes to the Edge browser. Once we manipulate those, we can then set our scope tags and indicate where we want to assign them. We could go in and set it up for certain groups of users that we've defined, or we could always say we want to make sure this gets applied to every user and every device. The last step is to create this profile. So now we have this nice Edge profile based on this good Microsoft Edge security baseline that we have, and we can deploy this out to our systems.
Notice we've done that by assigning it to all of our devices. After the next sync of our clients, as far as their Edge settings go, they'll be in compliance with the security baseline that we borrowed from Microsoft. That's the one that Microsoft made available to us.
And remember, there were other security baselines for you to look at, too. There's the Windows 10 security baseline, the Defender Advanced Threat Protection baseline, and then of course the Microsoft Edge baseline that we took a look at in this demonstration. Notice that these have versions, too; you're going to have situations where you get new additions of them from Microsoft, and the version increments at that point.

10.5.6 Sideload an App (Demo Video)

Transcript:

In this demonstration, we'll walk through the process of sideloading an app on a Windows 10 workstation system.

Sideloading is the act of installing apps that we create or own on a Windows system without going through the Microsoft Store. This is a significant change from earlier versions of Windows, such as Windows 8 and Windows 8.1.
In Windows 8 and 8.1, sideloading an app was discouraged, and was therefore very difficult to implement. On Windows 10 that has all changed. Sideloading is relatively easy now. With that in mind, let's walk through the process that you need to follow in order to sideload an app.
The first thing we must do is configure Windows to allow sideloading because sideloading is typically not allowed by default. To do this, you right-click Start and select Settings app. Then go to Update and Security > For Developers. Here you have three options.
First, there is Microsoft Store apps, then Sideload apps, and finally Developer mode. This is already set to allow Sideloading apps, so we don't have to change anything. On some versions of Windows, the top option, Microsoft Store, is set as the default. When you change to Sideload apps, you get a message warning of the danger of installing an app by sideloading rather than going through the Microsoft Store.
You can also go into Developer mode. It is similar to the sideloading option, but it also includes advanced development features, which we're not going to work with today. We're just going to use the Sideload apps option. Close this window.
There is another way you can enable sideloading an app and that is through the Group Policy Editor. The great thing about Group Policy is that if you do this on the domain, all systems on the domain that are assigned this Group Policy will be able to sideload an app.
Deciding if you want to do that or not depends on the number of systems involved. To show you how to do that, we'll go into the Local Group Policy and configure this. Remember, you typically would do this on the server, but the settings are the same.
Go down to Search, type â€˜gpedit', and then select Edit Group Policy from the list. The Local Group Policy Editor opens. We'll adjust the size so we can see things better.
Under Computer Configuration, expand Administrative Templates, Windows Components and select App Package Deployment. Next, double-click this setting right here, Allow all trusted apps to install.
When the dialog box opens you will see that by default it's set to Not Configured. We can enable it here, if we want. We're not going to enable it because we already did in the Settings App. This is just another way of doing it, especially if your system is part of a domain.
As always, down here under Help, you can read more about what this setting does if you are not sure. Let's exit out of these windows now.
With sideloading enabled, now we can practice sideloading an app. First, you must have an app to sideload. We've already done that on this system. You could create your own app, but who has time for that?
For this demo, we downloaded one and saved it to the hard disk. Key thing here is that we did not use the Microsoft Store. We determined where this app was hosted on the web and downloaded it. Note that this app has an APPX file extension. This file is the app that we're going to sideload.
Before continuing, we want to check the security certificate for this app. We downloaded the app from the internet, so, you want to make sure the digital signature is OK before you install it. Also keep in mind, if this was an app that we created, we'd have to create a certificate and install that certificate.
Without a certificate, Windows will not allow that app to install. We know this because we tried to do it and guess what? It doesn't work. There are probably work arounds to make it work but that is beyond the scope of this demo.
So, let's check the digital signature of this app. We'll right-click and go to Properties and click the Digital Signatures tab. Next, we'll select the certificate in the Signature list box. Click Details. Under Digital Signature Information, it says, "Hey, this signature is OK." That's a positive thing and we should not have any problems with our app. Click Cancel to close the dialog box.
So, now we have enabled sideloading on the system. We've checked the certificate that was used to sign the app and we've verified that the signature on the app file is valid. The next thing we must do is to sideload the app.
Starting with the Windows 10 Anniversary Edition, you can double click the APPX file and install the app. When we do that, the app installer launches. Here, you can see the name of the app, publisher info, version, and some other info.
If we click Install, the app installs. Let's do things the hard way. We'll install this app using a PowerShell cmdlet. The first thing we must do is run PowerShell. Close the installer here.
We'll right-click the Start and then click Windows PowerShell (Admin). We'll elevate privileges and PowerShell opens.
To make things easier, we put the app into a folder on the C: drive named Install. Let's change directories and go to that folder. To do that type â€˜cd c:/Install' and press Enter. Let's do a â€˜dir' command to see the contents of the folder. The APPX file is there. This makes things easier as you will see in a minute.

Now that we're in the right directory, all we do is type 'Add-AppPackage' followed by the name of the package file that we want to install. We type â€˜./' and instead of typing out this long filename, we'll highlight it, select Edit, right-click, choose Copy, come down here and right-click. When we do, it gets pasted in. Hit Enter and wait a minute while the app is installed on the system.
Something happened, but are we sure? Well, let's see if the app is installed. We'll close these windows, click Start, and scroll down to find the app we just installed. Click it and it opens.
If for some reason we don't want this app any longer, we can uninstall it like we do any Microsoft Store app. You find it in the list, right-click, select Uninstall, select it from the list again, click Uninstall again, and the app is gone.
That's it for this demo. In this demonstration we walked through the process for sideloading an app on Windows 10. First, you must have the app that you want to install. Then you must enable sideloading. You verify that the digital signature on the app is valid, and then use the add appx package PowerShell command to install the app file.

10.5.7 Implement Mobile Device Management

10.5.8 Practice Questions (Section Quiz)

q_mbl_dev_conn_cell_secp8

Your organization recently purchased 18 iPad tablets for use by the organization's management team. These devices have iOS pre-installed on them.

To increase the security of these devices, you want to apply a default set of security-related configuration settings.

What is the BEST approach to take to accomplish this? (Select two. Each option is part of a complete solution.)

Answers:

Require users to install the configuration profile.

Join the tablets to a Windows domain.

Configure security settings in a Group Policy Object.

Configure and distribute security settings in a configuration profile.

***Enroll the devices in a mobile device management (MDM) system.**

***Configure and apply security policy settings in a mobile device management (MDM) system.**

Explanation:

A mobile device management (MDM) solution can push policies directly to each tablet device over a network connection. This option enables policies to be remotely enforced and updated without any action by the end user. The tablet devices must be enrolled in the MDM system before the policy settings can be applied.

One of the key problems associated with managing mobile devices is the fact that they can't be joined to a Windows domain. This means Group Policy can't be used to automatically push security settings to mobile devices.

For devices running Apple's iOS operating system, security settings can be distributed in a configuration profile. The profile can be defined so that only an administrator can delete the profile, or you can lock the profile to the device so that it cannot be removed without completely erasing the device. However, this option relies on the end user to install the profile, which can be problematic.

It's also not a dynamic strategy. Making even the smallest change to your mobile device security policies requires a great deal of effort.

q_mbl_dev_conn_geo_tag_secp8

Recently, a serious security breach occurred in your organization. An attacker was able to log in to the internal network and steal data through a VPN connection using the credentials assigned to a vice president in your organization.

For security reasons, all individuals in upper management in your organization have unlisted home phone numbers and addresses. However, security camera footage from the vice president's home recorded someone rummaging through her garbage cans prior to the attack. The vice president admitted to writing her VPN login credentials on a sticky note that she subsequently threw away in her household trash. You suspect the attacker found the sticky note in the trash and used the credentials to log in to the network.

You've reviewed the vice president's social media pages. You found pictures of her home posted, but you didn't notice anything in the photos that would give away her home address. She assured you that her smartphone was never misplaced prior to the attack.

Which security weakness is the MOST likely cause of the security breach?

Answers:

***Geotagging was enabled on her smartphone.**

Sideloaded apps were installed on her smartphone.

Weak passwords were used on her smartphone.

A Christmas tree attack was executed on her smartphone.

Explanation:

Geotagging embeds GPS coordinates within mobile device files (such as image or video files) created with the device's camera. While this feature can be useful in some circumstances, it can also create security concerns. In this scenario, the vice president probably posted geotagged images to her social media accounts. The attacker likely analyzed the images to discover where she lived and then conducted a dumpster dive attack that yielded the sticky note with the vice president's VPN credentials. The best way to remedy this weakness is to simply disable this functionality in the mobile devices you manage.

Sideloaded apps can only be installed if the device administrator has specifically configured the device to allow them, so this is an unlikely cause.

A weak smartphone password is a concern, but this would not be the cause of the exploit if the device were always in the vice president's possession.

A Christmas tree attack is used to fingerprint network devices, not to gather personally identifiable information.

q_mbl_dev_conn_jailbreak_secp8

A software technician presents a forum on sideloading and jailbreaking to a group of new mobile users.

Which of the following points will the technician include in their discussion of the use of jailbreaking? (Select two.)

Answers:

***It is a method used to gain elevated privileges and access to system files on mobile devices.**

***It allows users to install unauthorized applications and customize device appearance and behavior.**

It refers to the installation of applications from sources other than the official application store of the platform.

It does not undergo the same scrutiny and vetting process as those on official application stores.

It provides the ability to share internet connectivity to other devices.

Explanation:

Jailbreaking is a method used to gain elevated privileges and access to system files on mobile devices.

Jailbreaking allows users to install unauthorized apps, customize the device's appearance and behavior, access system files, and bypass restrictions implemented by Apple.

Sideloading refers to installing applications from sources other than the official app store of the platform, such as Google's Play Store for Android or Apple's App Store for iOS.

While sideloading allows for greater software flexibility and choice, it poses significant risks as sideloaded apps do not undergo the same scrutiny and vetting process as those on official app stores.

Tethering (not jailbreaking) is the ability to share internet connectivity to other devices.

q_mbl_dev_conn_lock_secp8

Which of the following mobile device security considerations disables the ability to use the device after a short period of inactivity?

Answers:

Remote wipe

***Screen lock**

GPS

TPM

Explanation:

A lockout (or screen lock) disables the ability to use the device after a short period of inactivity. The correct password or personal identification number (PIN) unlocks the device.

Remote wipe, also known as sanitization, remotely clears specific, sensitive data on a mobile device. This task is also useful if you are assigning the device to another user or after multiple incorrect password or PIN entries. Data encryption also ensures data confidentiality on the device. Voice encryption (on mobile phones) ensures data confidentiality during transit.

Global Positioning System (GPS) tracking can assist in a device's recovery by displaying its current location.

Trusted Platform Module (TPM) is a hardware chip on the motherboard that can generate and store cryptographic keys to check the integrity of startup files and components.

q_mbl_dev_conn_security_considerations_secp8

Which of the following is NOT a common security consideration for mobile devices?

Answers:

Remote wipe

Geofencing

Full device encryption

***Water resistance**

Explanation:

The following is NOT a common security consideration for mobile devices:

While water resistance can be an important feature for mobile devices, it is not a security consideration. It is more related to the physical durability and resilience of the device, not the protection of data or prevention of unauthorized access.

The following are common security considerations for mobile devices:

Remote wipe is a common security feature for mobile devices. It allows an administrator or device owner to remotely erase all data on the device, which can be especially useful if the device is lost or stolen.

Geofencing is a security feature that restricts the use of a device to a specific geographical area. If the device leaves the designated area, certain functionalities can be disabled or alerts can be sent.

Full device encryption is a security feature that encrypts all data on the device. This means that even if someone gains physical access to the device, they cannot access the data without the encryption key (usually a password or PIN).

q_mbl_dev_conn_sideload_01_secp8

A cyber team presents a discussion on the use of sideloading and jailbreaking to a group of board members.

Which of the following BEST describes sideloading? (Select two.)

Answers:

***It refers to the installation of applications from sources other than the official application store of the platform.**

***It does not undergo the same scrutiny and vetting process as those on official application stores.**

It is a method used to gain elevated privileges and access to system files on mobile devices.

It allows users to install unauthorized applications and customize device appearance and behavior.

It provides the ability to share internet connectivity to other devices.

Explanation:

Sideloading refers to installing applications from sources other than the official app store of the platform, such as Google's Play Store for Android or Apple's App Store for iOS.

While sideloading allows for greater software flexibility and choice, it poses significant risks as sideloaded apps do not undergo the same scrutiny and vetting process as those on official app stores.

Jailbreaking is a method used to gain elevated privileges and access to system files on mobile devices.

Jailbreaking allows users to install unauthorized apps, customize the device's appearance and behavior, access system files, and bypass restrictions implemented by Apple.

Tethering (not sideloading) provides the ability to share internet connectivity to other devices.

q_mbl_dev_conn_sideload_02_secp8

An IT administrator observes that a significant number of mobile devices within the organization have applications installed from outside official app stores.

Concerned about the security implications, the administrator decides to assess the vulnerabilities introduced by this practice.

Which of the following BEST describes the process that allows users to install applications on their devices from sources other than official app stores, potentially exposing the device to malware or unauthorized data access?

Answers:

Rooting

***Sideload**

Jailbreaking

Keylogging

Explanation:

Sideloading refers to the process of installing applications from sources other than official app stores. It poses a risk as the sideloaded apps might not undergo the same security checks as those in official stores.

While rooting provides users with elevated privileges on their devices, allowing them to modify the operating system and bypass certain restrictions, it does not specifically pertain to the installation of apps from outside official app stores.

Jailbreaking allows users to bypass restrictions imposed by Apple and install unauthorized apps, but the term "sideloading" more universally describes the act of installing apps from unofficial sources.

Keylogging is a method used by attackers to record a user's keystrokes, capturing everything typed.

q_mbl_dev_conn_types_secp8

Which of the following is NOT a connection type used by mobile devices?

Answers:

WiFi

Bluetooth

NFC

***HDMI**

Explanation:

The following is NOT a connection type used by mobile devices:

HDMI (High-Definition Multimedia Interface) is a type of connection used primarily for transmitting high-quality video and audio from a device to a display, such as a TV or monitor. While some mobile devices may support HDMI output through a special adapter, it is not a common connection type used by mobile devices in the same way as WiFi, Bluetooth, or NFC.

The following are common connection types used by mobile devices:

WiFi is a common connection type used by mobile devices to connect to the internet or local networks wirelessly.

Bluetooth is another common connection type used by mobile devices for short-range connections to other devices such as headphones, speakers, or other mobile devices.

NFC (Near Field Communication) is a connection type used by mobile devices for very short-range connections, often used for things like contactless payments or transferring data between devices by touching them together or bringing them very close to each other.

q_mbl_dev_conn_unauthorized_apps_secp8

An IT security specialist at a mid-size corporation observes a trend of unauthorized apps appearing on company-provided mobile devices. The specialist suspects the employees are either sideloading apps or have jailbroken their devices.

What steps should the security specialist take to verify the cause of the unauthorized applications and to re-establish proper security protocols? (Select two.)

Answers:

***Conduct device audits to identify unauthorized applications and to detect any signs of jailbreaking or sideloading.**

***Implement mobile device management (MDM) policies to restrict unauthorized application installation.**

Purchase new mobile devices to replace all current ones.

Hire external IT consultants to manage mobile device usage.

Implement a credential management policy.

Explanation:

Audits allow the IT security specialist to directly identify whether unauthorized applications are present, which could indicate sideloading or jailbreaking activities.

Implementing MDM policies ensures that only authorized apps, vetted for security and functionality, are on company devices, reducing the risk of security breaches.

The devices themselves are not the problem; the problem is the behavior leading to sideloading or jailbreaking, which could easily recur on new devices without proper management and policies.

Organizations employ external consultants for broader strategic initiatives when internal resources face an overwhelming amount of tasks, not for routine security management tasks.

Credential management is a feature implemented in most mobile operating systems for storing usernames and passwords for the end user. A good example is Credential Manager in Windows RT. However, implementing a policy for credential management will not help with verifying the cause of the unauthorized applications and re-establishing proper security protocols.

q_mbl_dev_conn_white_secp8

Your organization recently purchased 20 Android tablets for use by the organization's management team.

To increase the security of these devices, you want to ensure that only specific apps can be installed.

Which of the following would you implement?

Answers:

App blacklisting

Credential manager

***App whitelisting**

Application control

Explanation:

App whitelisting is the process of defining specific apps that users can have on their mobile devices. Apps not on the whitelist are not allowed to be installed.

Blacklisting apps is the process of defining specific apps that users cannot have on their mobile devices.

The credential manager function that is implemented in most mobile operating systems can store usernames and passwords for the end user.

Application control is implemented by each mobile operating system. It determines how apps are installed and where they come from.

q_mbl_dev_conn_wipe_secp8

A smartphone was lost at the airport. There is no way to recover the device.

Which of the following ensures data confidentiality on the device?

Answers:

***Remote wipe**

Screen lock

GPS

TPM

Explanation:

Remote wipe, also known as sanitization, remotely clears specific, sensitive data on a mobile device. This ensures that whoever has the device cannot see the sensitive data. This task is also useful if you are assigning the device to another user or after multiple incorrect entries of the password or PIN. Data encryption also ensures data confidentiality on the device. Voice encryption (on mobile phones) ensures data confidentiality during transit.

Global Positioning System (GPS) tracking can assist in the recovery of the device by displaying its current location.

A lockout (or screen lock) disables the device's interface after a short period of inactivity. The correct password or personal identification number (PIN) unlocks the device.

Trusted Platform Module (TPM) is a hardware chip on the motherboard that can generate and store cryptographic keys to check the integrity of startup files and components.

q_mbl_dec_sec_config_secp8

Which of the following is the recommend Intune configuration?

Answers:

Hybrid MDM

***Intune Standalone**

Account portal

Company portal

Explanation:

Intune Standalone is the recommended deployment method. Intune Standalone is a cloud-only solution that is managed using a web console that can be accessed from anywhere with internet access.

Hybrid MDM with Configuration Manager is a solution that combines Intune's mobile device management capabilities into Configuration Manager.

The Account portal is used to manage subscriptions, users, groups, and domains.

The Company portal is used by end users to manage their own account and enroll devices.

q_mbl_dec_sec_enroll_secp8

You are the IT manager of a medium-sized company that has recently adopted Windows Intune for mobile device management. The company has a mix of Windows, iOS, and Android devices. You have already added Intune users and defined Intune policies.

What should be your next step in the system configuration process?

Answers:

Create additional administrative accounts

***Enroll mobile devices**

Synchronize users and groups from your Active Directory domain

Deploy software to user accounts

Explanation:

Enroll mobile devices is the correct answer. After adding users and defining policies, the next step in the system configuration process for Windows Intune would be to enroll the mobile devices that will be managed by the system. This allows the defined policies to be applied to these devices.

While it's important to have administrative accounts for managing the system, the question scenario indicates that users have already been added to Intune. The next logical step would be to enroll the devices that these users will be using.

While synchronizing users and groups from your Active Directory domain is a possible step in the configuration process, the scenario indicates that users have already been added to Intune. Therefore, the next step would be to enroll the devices that these users will be using.

While deploying software is an important part of managing devices with Intune, it would be premature to do this before the devices have been enrolled. The next logical step would be to enroll the devices that will be managed by the system.

q_mbl_dec_sec_mdm_01_secp8

Which of the following is a solution that pushes security policies directly to mobile devices over a network connection?

Answers:

Credential Manager

Group Policy

***Mobile device management (MDM)**

Application Control

Explanation:

Mobile device management (MDM) is a solution that pushes security policies directly to each device over a network connection. MDM solutions enable policies to be remotely enforced and updated without any action by the end user. Many companies have MDM products, including Apple, Cisco, and Microsoft.

The Credential Manager function that is implemented in most mobile operating systems can store usernames and passwords for the end user.

Group Policy cannot be used to automatically push security settings to mobile devices. This is because the devices cannot be joined to a Windows domain.

Application Control is implemented by each mobile operating system. It determines how apps are installed and where they come from (App Store, etc.).

q_mbl_dec_sec_mdm_02_secp8

A large financial institution recently adopted a bring your own device (BYOD) policy. It understands the cost and flexibility advantages of this approach but is concerned about the potential security implications.

Specifically, the institution wants to ensure that its sensitive data remains protected even when accessed from or stored on employees' personal devices.

What would be the MOST effective strategy to safeguard data in this context?

Answers:

Regularly update the company's firewall and antivirus software

***Deploy a mobile device management (MDM) solution**

Implement mandatory password changes every 30 days

Conduct regular security training for employees

Explanation:

An MDM solution allows a company to manage, secure, and enforce policies on employees' mobile devices, even if they are personal devices.

While updating the firewall and antivirus software is a good general practice for any organization, it would not specifically address the security risks associated with a BYOD policy.

While regular password changes can enhance security by limiting the effectiveness of stolen or guessed passwords, they do not directly address the risks associated with a BYOD policy.

While security training is an important aspect of any organization's cybersecurity strategy, it would not directly mitigate the risks associated with a BYOD policy.

q_mbl_dec_sec_mdm_03_secp8

A large firm requires better control over mobile users' access to business applications in the cloud. This access will necessitate single sign-on and support for different device types.

Given the need for risk transference and ease of recovery, what solution should the company consider using?

Answers:

***Third-party mobile device management (MDM)**

Custom in-house software

Virtual private network (VPN) connections

Cloud-hosted desktops

Explanation:

Third-party MDM solutions allow single sign-on, device diversity support, and cloud application access control. They transfer some risk to the provider via service level agreements (SLAs) and often feature rapid recovery options.

While it could meet the exact needs of the firm, developing and maintaining in-house software presents risks and complexities. Additionally, it does not facilitate risk transference as the company retains all responsibility.

Virtual private networks (VPNs) secure network connections but do not manage device-level access controls or single sign-on. Moreover, VPNs do not inherently offer risk transference or ease of recovery.

While cloud-hosted desktops can provide a consistent environment accessible from any device, they do not offer the mobile-specific control and risk transference that a third-party MDM solution does.

q_mbl_dec_sec_mdm_04_secp8

An organization implemented a bring your own device (BYOD) policy for employees to use their mobile devices for work-related tasks. The organization's IT department identified concerns about the security risks associated with BYOD.

They determined that employees' mobile devices must meet the security requirements to protect sensitive company data.

Considering the scenario, which of the following measures is the MOST effective way to enhance the security of employees' mobile devices under the BYOD policy?

Answers:

***Using mobile device management (MDM) solutions to centrally control employees' mobile devices.**

Providing employees with company-owned mobile devices.

Restricting all access to company resources from mobile devices.

Enforcing complex passwords for all employee mobile devices.

Explanation:

Mobile device management (MDM) solutions enable the organization to control employees' mobile devices centrally, enforce security policies, perform remote data wipes in case of loss or theft, and ensure devices remain updated and compliant with security standards.

Although company-owned devices can offer better control, they may not always be feasible under a bring your own device (BYOD) policy and can incur significant costs for the organization.

Completely restricting access to company resources may hamper productivity and negate the advantages of the BYOD policy.

While strong passwords are crucial, relying solely on them does not encompass all security concerns related to BYOD. An MDM solution presents a more comprehensive approach.

q_mbl_dec_sec_mdm_cloud_secp8

The IT team of a medium-sized company plans to implement a mobile device management (MDM) solution to enhance security and streamline the management of its growing number of mobile devices.

The company has employees who use various devices, such as smartphones and tablets, for work tasks in and out of the office.

The IT team needs to choose the MOST appropriate deployment model for their MDM solution to ensure seamless device management and data protection.

Which deployment model for MDM provides the highest level of control and security for the company's diverse mobile devices?

Answers:

***Cloud-based deployment**

On-premises deployment with limited network access

Hybrid deployment with minimal cloud integration

Bring your own device (BYOD) deployment with partial control

Explanation:

A cloud-based MDM deployment allows the IT team to manage mobile devices centrally from the cloud, providing a high level of control, flexibility, and security.

An on-premises MDM deployment requires local infrastructure and may have limited access to manage devices outside the corporate network. This approach might not be suitable for employees using mobile devices off-site.

A hybrid MDM deployment combines on-premises and cloud components. While it offers some control, the minimal cloud integration may limit the ability to manage devices effectively, especially when employees are remote.

BYOD deployment allows employees to use personal devices for work, but it may not provide the desired level of control and security needed to protect sensitive data on diverse devices.

q_mbl_dec_sec_policies_secp8

The IT manager has tasked you with configuring Intune. You have enrolled the devices and now need to set up the Intune policies.

Where would you go to set up the Intune policies?

Answers:

***In the Admin portal, select Policy > Add Policy.**

In the Company portal, select Policy > Add Policy.

In the Admin portal, select Management > Policy > Add Policy.

In the Company portal, select Management > Policy > Add Policy.

Explanation:

To set up Intune policies, access the Admin portal and then select **Policy > Add Policy**.

q_mbl_dec_sec_portal_secp8

Which of the following Intune portals is used by end users to manage their own account and enroll devices?

Answers:

Admin portal

Add Intune Users

Account portal

***Company portal**

Explanation:

The Company portal is used by end users to manage their own account and enroll devices.

The Admin portal is used to manage enrolled devices and policies.

Add Intune Users is a configuration task that is completed in the Account portal.

The Account portal is used to manage subscriptions, users, groups, and domains.

q_mbl_dec_sec_settings_secp8

Your organization recently purchased 20 Android tablets for use by the organization's management team. You are using a Windows domain.

Which of the following should you use to push security settings to the devices?

Answers:

***Intune**

Credential Manager

Group Policy

Application Control

Explanation:

Intune is Microsoft's cloud-based mobile device management (MDM) platform that allows a network administrator to remotely manage and secure mobile devices.

The Credential Manager function that is implemented in most mobile operating systems can store usernames and passwords for the end user.

Group Policy cannot be used to automatically push security settings to mobile devices. This is because the devices cannot be joined to a Windows domain.

Application Control is implemented by each mobile operating system. This determines how apps are installed and where they come from.

q_mbl_dec_sec_windows_server_secp8

Which of the following operating systems does Windows Intune NOT support?

Answers:

Windows 10

Apple iOS 8.0 and later

Google Android 4.0

***Windows Server**

Explanation:

The document clearly states that Windows Intune cannot be used to manage Windows Server.

The following operating systems are supported by Windows Intune:

Windows 10 (Home, S, Pro, Education, and Enterprise versions)

Apple iOS 8.0 and later

Google Android 4.0

10.6 Mobile Device Management

As you study this section, answer the following questions:

What are four methods of mobile device management (MDM)?

What are the benefits of implementing mobile application management (MAM)?

What do Windows Information Protection (WIP) policies provide?

How does Intune help you to secure data?

In this section, you will learn to:

Enroll devices and perform a remote wipe.

The key terms for this section include:

Term	Definition
Windows Information Protection	A technology that helps protect against data leakage on company-owned and personal devices without disrupting the user experience.
Network fencing	Location compliance, known as network fencing, allows you to keep devices outside your corporate network from accessing network resources.
Mobile device management	The administration of mobile devices. MDM software generally allows for tracking devices; pushing apps and updates; managing security settings; and remotely wiping the device.
Mobile application management	The administration of applications on a mobile device. MAM software allows a system administrator to remotely install or remove organizational apps and to disable certain functions within the apps.
Enterprise mobility management (EMM)	A combination of MDM and MAM solutions in one package. EMM allows a system administrator to remotely manage hardware and applications on a mobile device.
Unified endpoint management (UEM)	An all-in-one device management solution. UEM allows a system administrator to manage local and mobile devices, including Internet of Things devices.
Bring your own device (BYOD)	The practice of having employees use their own personal mobile devices for business related tasks.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
TestOut Security Pro	2.2 Harden network devices 2.2.6 Bring Your Own Device (BYOD) security 3.2 Implement application defenses 3.2.1 Implement an application allow list

CompTIA Security+ SY0-701	2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Application allow list 3.1 Compare and contrast security implications of different architecture models. Considerations Ease of deployment 4.1 Given a scenario, apply common security techniques to computing resources. Mobile solutions Mobile device management (MDM) Deployment models Bring your own device (BYOD) 4.2 Explain the security implications of proper hardware, software, and data asset management. Disposal/decommissioning Sanitization Destruction Data retention

10.6.1 Mobile Device Management (Lesson Video)

Transcript:

Today, mobile devices are used in more workplaces than ever before. They create all kinds of new possibilitiesâ€”and all kinds of new problems. So managing mobile devices is a major focus for most organizations.

Most employees bring a personal mobile device to work, usually a cell phone, tablet, or laptop. When these personal electronics are used for business activity, they're called BYOD devices, which stands for bring your own device.
Before mobile devices were common, every device that connected to a network was stationary, such as a desktop or printer, so you could add it to a domain and manage it with Group Policy settings.
But it's not that simple anymore. Organizations need to manage mobile devices and enforce policies to secure their data. If an employee copies sensitive data to a device, the organization needs to be sure that the data will be kept safe outside the organizational network. This is where Mobile Device Management policies come in.
We're going to cover the four main types of mobile device management: Mobile Device Management, Mobile Application Management, Enterprise Mobility Management, and Unified Endpoint Management.
Let's start with Mobile Device Management, or MDM. MDM allows IT administrators to remotely manage a mobile device, even if it's a personally owned device used for work.
MDM lets you track the device, push apps and updates, manage security, and even remotely wipe the device.

This solution works well for company-owned devices, but the release of the iPhone in 2007 caused a huge increase in the number personal devices brought to work and used for work-related purposes, such as email.
Employees didn't want their employers to have too much control over their personal devices. This is when Mobile Application Management solutions were created.
Mobile Application Management, or MAM, solutions focus on managing the applications on a mobile device, not the device itself.
Applications that the organization has developed or any application that the organization provides licenses for falls under MAM policies.
The organization can put limitations on these apps, such as disabling copy and paste functions. IT administration can uninstall the app and the data related to it in case the device is lost or stolen.
As more devices were release and their use spread, MDM and MAM solutions evolved to keep up with changing demands and eventually merged into a solution called Enterprise Mobility Management.
One of the main drawbacks of MDM and MAM solutions is that there are so many different types of devices and operating systems. Each device type requires separate management tools and systems.
Enterprise Mobility Management, or EMM, solutions solve this problem. EMM is a combination of MDM and MAM methods into one package solution. EMM is hardware-agnostic and can remotely manage a mobile device's hardware and applications.
One of the more popular solutions for Enterprise Mobility Management is Microsoft's Intune.
Intune is a part of the Microsoft Enterprise Mobility and Security Suite that's accessed through an organization's Azure portal. Intune allows IT administrators to manage mobile devices and apps, control access to data, and ensure that devices comply with security policies.
Microsoft Intune is included with any Enterprise agreement of at least 500 users, and it supports all mobile device types.
I probably don't have to tell you that integrating device security with Azure's Active Directory make managing mobile devices much, much simpler.
Of course, IT administrators need to worry about managing everything else that's on their network, too: desktop computers, printers, Internet of Things devices, and wearables. This need was met by the creation of another solution called Unified Endpoint Management, or UEM.
UEM tools provide a single point of management for all network devices. Essentially, they are a marriage of traditional device management and Enterprise Mobile Device Management solutions.
All right, that's all for this video. In this lesson, we looked at mobile device management solutions, including Mobile Device Management, Mobile Application Management, Enterprise Mobility Management, and Unified Endpoint Management. We also talked about Microsoft's EMM solution, Intune.

10.6.2 Mobile Device Management Facts

The use of mobile devices in the workplace has increased rapidly over the past few years. The management of these devices has become a big concern for system administrators.

Many organizations allow users to bring their own devices and use them for work-related purposes. This practice, known as bring your own device (BYOD), requires the organization to develop a set of policies to manage these devices, which allow the organization to ensure that mobile devices are secured and can be managed remotely. There are four main types of mobile device management solutions.

This lesson covers the following topics:

- Mobile device management (MDM)
- Mobile application management (MAM)
- Enterprise mobility management (EMM)
- Unified endpoint management (UEM)

Mobile Device Management (MDM)

Mobile device management solutions allow IT administrators to remotely manage a mobile device, even if it's a personally owned device being used for work-related purposes. MDM focuses on managing the device itself but not the applications or software.

Mobile device management provides the ability to:

- Track the device.
- Push apps and updates (also known as provisioning the device).
- Manage security settings, such as lock screens, passwords, etc.
- Remotely wipe the device in case it is lost or stolen.

Mobile Application Management (MAM)

Mobile application management solutions focus on managing the applications on a mobile device but not the device itself. Licensed applications or custom-designed apps fall under MAM policies.

Mobile application management provides the ability to:

- Install and uninstall apps remotely.
- Update apps as needed.
- Limit functionality in an app as needed.

Enterprise Mobility Management (EMM)

Enterprise mobility management combines MDM and MAM solutions in one package. These policies allow a system administrator to remotely manage a mobile device's hardware and applications.

As different brands and manufacturers of mobile devices came on the market, the ability to manage them all became more difficult. Enterprise mobility management solutions address this problem by being able to manage multiple types of devices in a single package.

Microsoft's Intune is one of the most popular EMM solutions. Intune is included with any Windows Enterprise agreement of at least 500 users and supports all types of devices. Intune is integrated into the organization's Azure Active Directory, which simplifies device management even more. Intune allows the system administrator to:

- Manage mobile devices.
- Manage mobile apps.
- Control data access.
- Comply with security policies.

Unified Endpoint Management (UEM)

The need to manage many different devices has become an issue for organizations. Devices such as printers, workstations, servers, and others are managed in Active Directory. However, mobile devices need to be managed separately. A recent solution

to this is unified endpoint management. UEM is the next step in device management. These solutions provide a single point for all types of devices, including:

- Workstations.
- Printers.
- Mobile devices.
- IoT devices.
- Wearable devices.

UEM is the joining together of traditional device management and enterprise mobility management solutions.

10.6.3 Enroll Devices and Perform a Remote Wipe (Demo Video)

Transcript:

There are times when it may be necessary to remove company data from a device that is assigned to one of your users. Now, you could jump in a cab and go to the person's house, knock on the door, and demand to see the device, or you could use some of the cool features that Microsoft has created for us. In this demo, we're going to look at how to restart, retire, or wipe devices on a device remotely.

I'm already logged into Endpoint Manager. I'll come up to Devices and go over to the All Devices blade. Then, in my list of devices, select the Windows11-3 device. There is no particular reason why I picked this device for this demo. In your environment, you would obviously pick the one that you want to work with.
So, now we're seeing some of the basic properties for this device. I can do several things from here. Up here, we have Retire. I'll click on it. If you choose this option, it will remove company data from the device that is managed by Intune. It won't delete the user's personal data. There are some exceptions to what is removed, so make sure you read the documentation and understand what's happening before proceeding.
I don't want to do this, so I'll click No.
Now we'll look at how to wipe a device. I'll click on Wipe. Now a wipe is going to set the device back to a factory reset. You might do this if the person using the device has had an awkward dismissal from a company or the device is lost or stolen. You have two choices. You can wipe the device, but keep the enrollment state and associated account. The other option is to wipe even if the device loses power. It also says that the device might not run Windows 10 or later. This is the more extreme of the two. It's probably the right option if the device is lost or stolen. In fact, it's making me a little nervous. I'm going to click Cancel before I accidentally wipe my demo system!
Next, we have Delete a device. This one deletes the device, and you will no longer see it here in Intune. The device will no longer be able to reach company resources, and the company data may be wiped from the device.
We're going to look at the Restart feature, but first, let's talk about a few others. Here, we have Sync. Use this when you want to sync your device. Fresh Start will remove all preloaded Win32 apps. You can choose whether to retain user data or not. And finally, there are several more things you can do remotely. Now let's go back and look at how to restart a device remotely.
Now I'll click on Restart. I get a message here that basically asks if I'm sure about wanting to restart the device. It goes on to say that the users will not be automatically notified of the restart, and they might lose work. To prevent this, make sure your users are informed before you select this option. I know that there is no one using this device, so I'll go ahead and click on Yes here. You can see a message in the upper right-hand corner of the screen that says Initializing Restart.
Now I'll jump over this this other device and see what happens.
Okay. I'm on the Windows client here, and I've been waiting for a few minutes. It did not reboot instantly. I do have this message that says it's going to sign me out and Windows will shut down in two minutes. So, I'll pause the recording, wait for a few minutes, and see what happens.
Oay., That took about two minutes, and now my device is restarting.

That's it for this demo. In this demonstration, we covered the steps on how to restart, retire, or wipe devices on a device remotely in Intune.

10.6.4 Mobile Application Management (Lesson Video)

Transcript:

All organizations have mobile apps that they like to use. Due to the different types of device platforms as well at data security and ownership these apps can be a challenge to manage.

Mobile Application Management, or MAM, allows the organization to overcome these issues. Intune is Microsoft's MAM solution. MAM in Intune refers to the assortment of management features that lets the system administrator publish, push, configure, secure, monitor, and update mobile apps.
Each app in Intune goes through a life cycle. This cycle is Add, Deploy, Configure, Protect, and Retire. Intune provides a full range of tools to help you manage apps during the life cycle.
Intune allows the organization to develop its own app catalog, create its own self-service portal, and remotely manage apps.
There are a lot of apps available to perform different tasks. But it's important that you only use approved apps that your organization has licenses for and has tested to work with their systems.
An app catalog allows the organization to define which apps a user can and can't use. To put together the catalog, the system administrator often shortened to system admin adds the apps to Intune. Once added, security policies are applied to the apps themselves. But security isn't ensured if you use unapproved apps to access organizational data and resources.
When adding apps to the catalog, the system admin can assign them to specific users or groups. For example, tech support usually doesn't need to use the finance app that the accounting department uses. So that app wouldn't show up in their catalog.
One cool feature that was added to Intune is the ability to blacklist an app. These are apps that absolutely shouldn't be installed on a device that's accessing organizational resources. If the user has one of these apps installed, they'll receive an error message that they're unable to access company resources.
In a large organization, it's just not feasible for the network administrator often shortened to network admin to manually push apps out to all the different groups of devices. But a company can create a self-service portal using Intune that makes the distribution of apps easier for everyone.
Users can access the portal by using a web link. The most efficient way, though, is to have them install the Intune company portal app. When the user installs the app, they log in using their work credentials. The app then allows the user to access their company's portal.
When an organization adds an app to Intune, the system admin decides if it's mandatory to install or not. Intune pushes out mandatory app installs to devices within 24 hours.
Using the portal makes managing apps much easier for the system admins.
So, there's a lot that goes into managing the apps for an organization. That's why Intune is so valuable for its ease and simplicity. With users spread all over the world, knowing that you can remotely manage app installs and usage is a great benefit.
All app types except for the line-of-business apps automatically update as needed. Remember that line-of-business apps are those that someone created internally. So, those updates are pushed out manually through the company portal. Once you load updates to Intune, they should update themselves within 24 hours.
When an employee leaves the organization, the system admin needs to ensure that he or she takes away all access to company resources and removes any company data on the user's devices. Intune allows the admin to remotely remove apps and clear all data from the device without affecting the device itself.
That's it for now. In this lesson, we covered the basics of Mobile Application Management and how you can use Intune to facilitate this. We looked at how you can create a catalog of the apps that users need. Then we covered what a self-service portal is and how you can use it to make the management of apps easier. Finally, we reviewed how you can use Intune to remotely manage apps and even remove apps from user's devices.

10.6.5 Mobile Application Management Facts

Mobile application management (MAM) refers to the assortment of management features that lets a system administrator publish, push, configure, secure, monitor, and update mobile apps. The goal is to ensure users have the applications they need at all times while protecting the organization's data within the apps. This can be very challenging due to the wide variety of device platforms and application types. Intune is Microsoft's MAM solution in the Azure cloud.

This lesson covers the following topics:

- Mobile application management
- Intune application life cycle
- App deployment and update methods

Mobile Application Management

Microsoft app protection policies are rules that make sure the company's data is secure within an application. The user cannot move data or perform any action that is prohibited in a policy. Intune mobile device management (MDM) provides app protection policies that enable MAM to protect devices and data. MAM also provides protection through MAM without enrollment (MAM-WE) in Intune MDM. The following table describes the two possible configurations.

Configuration Option	Description
Intune MDM + MAM	Manage apps using MAM and app protection policies on devices enrolled in Intune MDM. In an MDM + MAM implementation, administrators use the Intune console in the Azure portal.
MAM-WE	Manage apps using MAM and app protection policies but with devices enrolled with third-party enterprise mobility management (EMM) providers. Sensitive data can be managed on any device, including personal devices.

App protection can require a PIN to launch an application.

Intune Application Life Cycle

Each app in Intune goes through a life cycle. Intune provides a full range of tools to help manage apps during each phase. The following table describes these phases.

Phase	Description
Add	Add the apps you would like to manage and assign them in Intune. You can add the following app types: Apps from the Windows Store Apps that are line-of-business apps written in-house Apps on the web Built-in apps

Deploy	Assign the app to users and devices you manage and monitor them on the Azure portal.
Configure	Update deployed apps with new versions using Intune.
Protect	Protect company data in deployed apps with conditional access to email and other corporate resources. Conditional access is based on the criteria you set in the app protection policies that lock down actions the users can perform on devices. Examples of locked-down actions include copying data and preventing app installation on rooted devices.
Retire	Remove apps that have reached end of life or become outdated and are no longer used.

App Deployment and Update Methods

The following table describes the three methods available to work with applications throughout their life cycle.

Method	Description
App catalog	An app catalog allows the organization to define the apps a user can and cannot use. Apps can be assigned to specific users and devices via groups to facilitate management. The catalog is configured to make available to specific users and groups only the apps that they have rights to access. An app can also be blacklisted so no user can use it to access company resources.
Self-service portal	In a large organization, it is not feasible for the network administrator to manually push apps out to all users and groups for all devices. Therefore, a company can create a self-service portal using Intune that makes the distribution of apps easier for everyone.
Remote management	All app types, except for the line-of-business apps, automatically update as needed. Updates can be uploaded into Intune, where they can be pushed out to users and updated within 24 hours. Administrators can push out updates for line-of-business apps through the company portal. When an employee leaves the organization, Intune allows the administrator to remotely remove apps and clear all data from the device without affecting the device itself.

10.6.6 Practice Questions (Section Quiz)

q_mdm_emm_secp8

Which of the following mobile device management (MDM) solutions is hardware-agnostic and supports many different brands of mobile devices?

Answers:

MAM

MDM

***EMM**

UEM

Explanation:

Enterprise mobility management (EMM) is the combination of MDM and MAM solutions in one package. EMM solutions are able to manage multiple brands and types of mobile devices in a single package.

Mobile application management (MAM) solutions focus on managing the applications on a mobile device, but do not manage the device itself.

Mobile device management (MDM) solutions allow IT administrators to remotely manage a mobile device even if it's a personally owned device used for work-related purposes.

Unified endpoint management (UEM) is the next step in device management. These solutions provide a single point for all types of devices.

q_mdm_mam_01_secp8

Mobile application management (MAM) provides the ability to do which of the following?

Answers:

***Remotely install and uninstall apps.**

Control data access.

Comply with security policies.

Manage mobile devices.

Explanation:

Mobile application management (MAM) solutions focus on managing the applications on a mobile device but not the device itself. Licensed applications or custom-designed apps fall under MAM policies.

Mobile application management provides the ability to:

Remotely install and uninstall apps.

Update apps as needed.

Limit functionality in an app as needed.

Microsoft Intune allows the system administrator to:

Manage mobile devices

Manage mobile apps

Control data access

Comply with security policies

q_mdm_mam_02_secp8

The IT department of a medium-sized company is exploring various mobile solutions to improve productivity and enable employees to work efficiently on their mobile devices. They aim to choose a solution ensuring data security and seamless integration with the existing infrastructure.

The team has narrowed the options to three potential mobile solutions: mobile device management (MDM), mobile application management (MAM), and corporate-owned personally enabled (COPE). Each solution offers different features and functionalities, and the IT team is assessing which one BEST meets the company's needs.

Which mobile solution focuses on securing and managing the applications installed on employees' mobile devices rather than the devices themselves?

Answers:

***Mobile application management (MAM)**

Mobile device management (MDM)

Corporate-owned personally enabled (COPE)

A combination of mobile device management (MDM) and mobile application management (MAM)

Explanation:

Mobile application management (MAM) focuses on securing and managing applications on employees' mobile devices. It allows the IT team to control app distribution, updates, and data access without directly managing the entire device.

Mobile device management (MDM) manages and secures the entire mobile device, including settings, configurations, and data.

While corporate-owned personally enabled (COPE) provides a degree of application management, its primary focus is on the complete ownership and management of mobile devices. The scenario seeks a solution focused on securing and managing the applications installed on employees' mobile devices.

While a combination of MDM and MAM is possible, the question specifically asks for a solution focusing on application management, making MAM the more suitable choice.

q_mdm_manage_secp8

What is the minimum number of users needed in a Windows Enterprise agreement for Intune to be included?

Answers:

No minimum

100

***500**

1,000

Explanation:

Intune is included with any Windows Enterprise agreement of at least 500 users and supports all types of devices.

q_mdm_mdm_secp8

Mobile device management (MDM) provides the ability to do which of the following?

Answers:

Update apps as needed.

***Track the device.**

Control data access.

Remotely install apps.

Explanation:

Mobile device management (MDM) solutions allow IT administrators to remotely manage a mobile device even if it's a personally owned device being used for work-related purposes.

Mobile device management provides the ability to:

Track the device.

Push apps and updates (this is also known as provisioning the device).

Manage security settings, such as lock screens, passwords, etc.

Remotely wipe the device in case it is lost or stolen.

Mobile application management provides the ability to remotely install and uninstall apps.

Microsoft Intune allows the system administrator to:

Manage mobile devices

Manage mobile apps

Control data access

Comply with security policies

q_mdm_uem_secp8

Which of the following mobile device management (MDM) solutions allows an organization to manage all devices, including printers, workstations, and even IoT devices?

Answers:

MAM

MDM

EMM

***UEM**

Explanation:

Unified endpoint management (UEM) is the next step in device management. These solutions provide a single point for all types of devices. This includes workstations, printers, mobile devices, IoT devices, and wearable devices.

Mobile application management (MAM) solutions focus on managing the applications on a mobile device, but not on managing the device itself.

Mobile device management (MDM) solutions allows IT administrators to remotely manage a mobile device even if it's a personally owned device being used for work-related purposes.

Enterprise mobility management (EMM) is the combination of MDM and MAM solutions in one package.

q_mam_add_secp8

Which of the following is the first phase of the Microsoft Intune application life cycle?

Answers:

Deploy

Configure

***Add**

Protect

Explanation:

The first phase of the Microsoft Intune application life cycle is to add the apps that are to be managed and assigned in Intune.

Deploy is the second phase.

Configure is the third phase.

Protect is the fourth phase.

q_mam_catalog_secp8

Which of the following app deployment and update methods can be configured to make available to specific users and groups only the apps that they have rights to access?

Answers:

Self-service portal

Remote management

BYOD

***App catalog**

Explanation:

An app catalog allows an organization to define the apps that a user can and cannot use. Apps can be assigned to specific users and devices via groups to facilitate management. The catalog is configured to make available to specific users and groups only the apps that they have rights to access. An app can also be blacklisted so no user can use it to access company resources.

A company can create a self-service portal using Intune that makes the distribution of apps easier for everyone.

With remote management, all app types (except for line-of-business apps) automatically update as needed.

Bring your own device (BYOD) is a policy that allows a user to use their personal device for business purposes.

q_mam_deploy_secp8

In which phase of the Microsoft Intune application life cycle would you assign an app to users and/or devices you manage and monitor them on the Azure portal?

Answers:

***Deploy**

Configure

Add

Protect

Explanation:

During the Deploy phase, apps are assigned to users and devices and then monitored on the Azure portal.

The Configure phase is when apps are updated using Intune.

Add is the first phase. This is when apps are added to Intune to be managed.

Protect is the fourth phase. This is the phase in which company data is protected.

q_mam_remote_01_secp8

Which of the following app deployment and update methods allows updates to be uploaded onto Intune where they can be pushed out to users within 24 hours?

Answers:

Self-service portal

***Remote management**

BYOD

App catalog

Explanation:

With remote management, all app types (except for line-of-business apps) automatically update as needed. Updates can be uploaded onto Intune where they can be pushed out to users within 24 hours.

A company can create a self-service portal using Intune. This makes the distribution of apps easier for everyone.

Bring your own device (BYOD) is a policy that allows a user to use their personal device for business purposes.

An app catalog allows an organization to define the apps that a user can and cannot use.

q_mam_remote_02_secp8

Which of the following app deployment and update methods allows an administrator to remove apps and clear all data from a device without affecting the device itself?

Answers:

Self-service portal

***Remote management**

BYOD

App catalog

Explanation:

With remote management, when an employee leaves an organization, an administrator can remotely remove apps and clear all data from a device without affecting the device itself.

A company can create a self-service portal using Intune that makes the distribution of apps easier for everyone.

Bring your own device (BYOD) is a policy that allows a user to use their personal device for business purposes.

An app catalog allows the organization to define the apps that a user can and cannot use.

q_mam_we_secp8

You are the IT manager of a large multinational corporation. The company has recently decided to implement a bring your own device (BYOD) policy, allowing employees to use their personal devices for work purposes.

The company has a diverse range of device platforms and application types. Your task is to ensure that the company's data is secure within applications on these devices, and that sensitive data can be managed on any device, including personal devices.

Which of the following configurations would be the MOST suitable for this scenario?

Answers:

Intune MDM + MAM

***MAM-WE**

App catalog

Self-service portal

Explanation:

MAM-WE is the correct answer. MAM-WE allows for the management of apps using MAM and app protection policies but with devices enrolled with third-party enterprise mobility management (EMM) providers. This means that sensitive data can be managed on any device, including personal devices, making it the most suitable option for a BYOD policy.

Intune MDM + MAM allows for the management of apps using MAM and app protection policies on devices enrolled in Intune MDM. However, this option is not the most suitable for a BYOD policy as it requires devices to be enrolled in Intune MDM, which may not be feasible or desirable for personal devices.

While an app catalog allows the organization to define the apps that a user can and cannot use, it does not provide the necessary security features required for a BYOD policy.

A self-service portal can make the distribution of apps easier, but it does not provide the necessary security features required for a BYOD policy.

10.7 BYOD Security

As you study this section, answer the following questions:

How would you remediate a tablet or phone infected with malware?

What is an acceptable use policy (AUP)? How does it benefit mobile security?

How does virtual desktop infrastructure (VDI) provide enhanced security and better data protection?

What is the difference between choose your own device (CYOD) and corporate owned, personally enabled (COPE)?

How can you prevent malicious insider attacks?

In this section, you will learn to:

Secure mobile devices.

Secure an iPad.

Create a guest network for BYOD.

The key terms for this section include:

Term	Definition
Bring your own device (BYOD)	A BYOD policy allows employees to use personal devices for work related tasks.
Acceptable use policy (AUP)	An AUP determines the rules for using corporate resources, such as internet access, computers, etc.
Virtual desktop infrastructure (VDI)	VDI is a technology that uses virtual machines and virtual desktops.
Choose your own device (CYOD)	In a CYOD system, the company provides a list of approved devices for an employee to choose from. The ownership and management of devices varies by organization.
Corporate owned, personally enabled (COPE)	In a COPE system, the company provides a list of approved devices for an employee to choose from. The company owns the device; the employee uses and manages the device.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
TestOut Security Pro	2.2 Harden network devices 2.2.6 Bring Your Own Device (BYOD) security 3.2 Implement application defenses 3.2.1 Implement an application allow list
CompTIA Security+ SY0-701	2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Application allow list Isolation 3.1 Compare and contrast security implications of different architecture models. Considerations Ease of deployment 4.1 Given a scenario, apply common security techniques to computing resources. Hardening targets

- Mobile devices
  - Wireless devices
    - Installation considerations
  - Mobile solutions
    - Mobile device management (MDM)
    - Deployment models
      - Bring your own device (BYOD)
      - Corporate-owned, personally enabled (COPE)
      - Choose your own device (CYOD)
    - Connection methods
      - Cellular
      - Wi-Fi
      - Bluetooth

4.2 Explain the security implications of proper hardware, software, and data asset management

- Disposal/decommissioning
  - Sanitization
  - Destruction
  - Data retention

4.5 Given a scenario, modify enterprise capabilities to enhance security.

- Network access control (NAC)

4.6 Given a scenario, implement and maintain identity and access management.

- Access controls

5.1 Summarize elements of effective security governance.

- Policies

	Acceptable use policy (AUP)

10.7.1 BYOD Security Issues (Lesson Video)

Transcript:

Let's spend a few minutes talking about managing mobile devices.

When managing a modern computer network, you need to take into account all of mobile devices that will be connected to that network from both a management perspective and from a security perspective. Most users today have more than one mobile device that they will use to complete their day to day work, including smart phones and tablets. These devices may be purchased by your organization, or they may be personal devices brought from home. This practice is sometimes referred to as bring your own device, or BYOD. While these devices allow employees to be more productive, they also create management issues and open up security holes in your network. Because these devices are so well liked, it really isn't feasible for you to try to prevent their usage. Instead, you need to formulate plans to address them in your overall management strategy.

A key issue to remember is the fact that these devices probably contain some type of sensitive information. The degree of sensitivity depends on your organization, the person's role, and the information downloaded to these devices. It is possible that sensitive information can leak out of your organization through one of these mobile devices. You need to define processes for managing these devices. Let's take a look at a few things you need to consider.

First, you should define a process for provisioning users with mobile devices. Remember, whenever you give an employee one of these devices, it can open up a security risk. You need to carefully control who gets these devices and what they put on them. Begin by defining a procedure for provisioning users with mobile devices. This ensures that you know exactly who has a mobile device and what they will use it for.

Next, you should define acceptable uses for these devices. There are several key aspects related to acceptable use; one is personal use, and the other is after normal hours use. Employment terms play a factor. If an hourly employee is issued a mobile device, and that employee uses the device after normal work hours for company purposes, such as answering emails or responding to requests, then that individual could be eligible for overtime pay. This issue also relates to personal use of the device. If an employee uses a company owned mobile device after hours for anything that's irresponsible, illegal, embarrassing, or even malicious, your organization may have a degree of liability. The liability would stem from the fact that the organization issued the device to the employee and didn't specify acceptable personal use guidelines. Therefore, you should include provisions in your AUP that explicitly defines what constitutes acceptable personal use and which activities are prohibited.

If your organization allows personally owned devices, then you must address the question of who owns company data if it gets copied to a user's device. Does the organization still own it, or does the user own it because it's on their personal device? To deal with this problem, your AUP should define the kind of data that is allowed on mobile devices, especially if the device is personally owned. It should also define the kind of data prohibited on mobile devices. You can implement information classification labels to make it clear to the user into which category a particular piece of data is sorted.

In addition, your AUP needs to address the threat of insider attacks. A malicious internal user could use a mobile device to conduct an insider attack. For example, the user could use the built-in camera to take pictures of sensitive internal information. They could copy sensitive data to the device's storage. They could use the built-in microphone to record conversations. They could use the built-in video function to record proprietary processes, and so on. They could then transmit this stolen information outside your organization without going through your organization's network security mechanism using the device's mobile broadband connection. This would bypass your intrusion protection systems, your firewall, and any other network security mechanisms you may have implemented. Essentially, data could be stolen and you will have no idea that it's been leaked or how it got out.

Because these devices have Wi-Fi or mobile broadband networking built-in to them, it is very difficult to prevent data leakage. If the user can download or capture sensitive information to the device, there is no technological means to prevent data from being transmitted. Accordingly, your acceptable use policy should specify where and when employees can possess mobile devices and how they can use them. For example, you could prohibit mobile devices in the high-security areas of your organization. You could specify in the AUP that any personally owned devices brought on site are subject to random searches.

Once your AUP has been defined, you need to develop a management plan for managing the mobile devices in your network, both company owned and personally owned. For example, one issue you need to be concerned with is

malware propagation. If a user's tablet or phone is infected with malware, the infection can easily spread to your organization's network when they connect their device to your organization's internal network.
One solution is to implement Network Access Control (NAC) so that devices can be remediated before allowing them on your network. The NAC can install the latest antimalware software updates to a device and then run a scan to ensure the device is clean before allowing it on your network.
Alternatively, you could implement a guest wireless network that's isolated from your organization's production network. In this configuration, a BYOD device connects to the guest network to gain Internet access, but is quarantined from the rest of your organization's production network. Using a guest wireless network prevents malware on a BYOD device from infecting your production systems.
You also need to consider policies and procedures for protecting data that is legitimately copied to mobile devices within the guidelines set in your AUP. Organizations spend a lot of time, effort, and money building internal security controls to protect their data. However, if a user copies that information to a mobile device, that data is at risk. For example, if the user loses the device, the data on that device may be compromised. All the firewalls, content filters, and intrusion detection systems that you setup on your internal network are completely ineffective at preventing this. If that device doesn't have the appropriate security settings, anyone who picks up that device will be able view the sensitive data.
To circumvent this risk, consider using a mobile device management (MDM) infrastructure, such as the Windows Intune service. You can require all mobile devices, even personally owned devices, to be enrolled in your MDM infrastructure. You can use this infrastructure to enforce mobile device security policies. For example, using an MDM, you can require enrolled devices to use some form of authentication, such as a PIN or (better yet) a password. You don't want just anyone to be able to pick up a mobile device and begin using it without having to authenticate in some way. Without a password or a PIN code, anyone who finds a lost mobile device could immediately access the information that has been saved on it.
Also consider implementing some type of device lockout with your MDM infrastructure. If a device is left on, but there has been no activity for a period time, the lockout feature should lock the device and require authentication to re-access it. For example, suppose I'm at the airport using my Smartphone. I set my phone down to get my luggage and I forget and leave it in the terminal. After a few minutes of inactivity, the lockout feature automatically locks the device and requires some type of authentication to get back in.
You can also use the MDM infrastructure to enable device encryption. Even if I require authentication and lockouts on enrolled mobile devices, there is still a risk that someone could physically open a lost or stolen device, remove its storage, and try to read its contents from a different system. To prevent this, you can enable device encryption. Without the correct encryption key, the contents of the device's storage are undecipherable. Again, this can help protect data on a device if it gets lost.
You can also use the MDM infrastructure to remotely wipe mobile devices. This feature sends out a command over the Internet to a lost or stolen mobile device that causes the contents of the device to be wiped. The ability to perform a remote wipe is essential if you allow sensitive company information to be copied to mobile devices. If the user loses a device, you need to be able to perform a remote wipe as quickly as possible. You can even use the MDM infrastructure to automatically wipe data from a device after a certain number of failed authentication attempts have occurred. If someone finds or steals a device and then repeatedly tries to guess its pin or password, all the data will be removed from the device.
Finally, you should implement some type of reporting process for your mobile devices. Identifying a lost or stolen device as quickly as possible is probably one of the most important components in your overall mobile device management strategy. If a user loses a device, or if it's stolen, the loss needs to be reported immediately. Remember, users will be either hesitant or embarrassed to let you know that the device that the organization paid for and issued to them is now gone. They may fear some type of retribution. In spite of this, you need to make sure they understand that getting the missing device wiped clean of sensitive data is the organization's primary concern. Make sure users understand that timing is critical. The longer a missing device goes unreported, the more time an attacker has to defeat its security mechanisms and the more likely the sensitive data it contains will be exposed.
So, in this lesson we talked about some things you can do to increase the overall security of the mobile devices used by your organization. We talked about implementing a procedure for provisioning mobile devices, defining an acceptable use statement, and using an MDM infrastructure. Then we looked at some general provisions you can use to protect the data on the device, such as using authentication, implementing a lockout, using remote wipe after failed authentication attempts, encrypting the device, and instructing users to report immediately if a device is lost or stolen.

10.7.2 BYOD Security Facts

In addition to mobile devices owned by your organization, you must also take into account personally owned mobile devices that employees bring to work and use to complete daily work-related tasks. This practice is sometimes referred to as Bring Your Own Device (BYOD). Even though it entails a host of security risks, this is a very common practice in the modern work environment.

This lesson covers the following topics:

- BYOD security issues
- Deployment model alternatives

BYOD Security Issues

Security administrators need to keep the following BYOD security issues in mind:

BYOD Issue	Description	Possible Remedies
Malware propagation	If a user's tablet or phone is infected with malware, the infection can be spread when they connect their device to the organization's network.	Consider implementing a network access control (NAC) solution that remediates devices before allowing them to connect to your network. Alternatively, consider implementing a guest wireless network that is isolated from your organization's production network. User-owned devices can connect to this network to gain internet access but are quarantined from the rest of your organization's production network.
Loss of sensitive data control	If a user copies sensitive data to their device, the organization could potentially lose control of that information. Even the question of who owns the data after it has been copied to the personal device becomes problematic. Consider the following scenarios: The user may not have implemented appropriate security settings on their device, allowing anyone who gains access to the device to view the sensitive data. The user may lose the device, allowing anyone who finds it to access the sensitive data. The device may become infected with malware, potentially exposing sensitive data.	Implement an acceptable use policy that defines which kinds of data are allowed on personally owned devices and which kinds of data are prohibited. Information classification labels can be useful when implementing this policy. Consider requiring personal devices to be enrolled with a mobile device management infrastructure, such as Windows Intune, to enforce mobile device security policies.

Malicious insider attacks	If a user is so inclined, they could use their mobile device to conduct a malicious insider attack. For example, they could: - Use the built-in camera, which nearly all modern mobile devices have, to take pictures of sensitive internal information. - Use the built-in microphone to record conversations. - Use the built-in video function to record proprietary processes and procedures. - Use the device's mobile broadband connection to transfer stolen data to parties outside the organization, bypassing the organization's network security mechanisms.	Implement an acceptable use policy that: - Specifies where and when mobile devices can be possessed within the organization. For example, the possession of mobile devices may be prohibited in high-security areas. - Notifies users that personally owned devices are subject to random searches if brought on-site.
Device management	If a user brings a personally owned device on-site, the organization needs to address clearly who is responsible for managing the device. Responsibility for the following needs to be defined: - Operating system updates - App updates - Anti-malware installation - Anti-malware definition updates	Relying on the end user to implement these updates is unwise. Instead, consider implementing a network access control (NAC) solution that remediates devices before allowing them to connect to your network.
Support	If a user brings a personally owned device on-site, the organization needs to clearly address who will provide support for the device and the apps used on the device. Will the organization's help desk provide support, or must the user depend upon support provided by the device manufacturer?	Implement an acceptable use policy that specifies: - Where users can get support for personally owned mobile devices. - Which apps are allowed for use with organizational data. - Where users can get support for these apps.

Deployment Model Alternatives

To better secure mobile devices used by company employees, consider the following deployment model alternatives to BYOD:

Corporate-owned device: A corporate-owned device strategy lets businesses more effectively monitor and control activities performed on mobile devices. One advantage of this model is that businesses can purchase devices at significant discounts. The corporate-owned model also includes the option of restricting mobile device use to the workplace only. However, employees who need access to corporate email and other data after hours may feel compelled to use their personal devices for such access.

Corporate-owned, personally enabled (COPE): The COPE model gives businesses significant control over device security while allowing employees to use the devices to access both corporate and personal data. Because the company owns the device, it can be secured more easily and wiped clean if lost or stolen. One disadvantage of this model is that employees who are not free to choose their own devices may bring their own anyway.

Choose your own device (CYOD): The CYOD model provides slightly more flexibility in giving users a limited selection of devices to choose from. However, since the devices are still corporate-owned, IT managers can implement more effective security measures to prevent breaches.

Virtual desktop infrastructure (VDI): VDI can be used with any of the above models, including BYOD, to allow mobile devices to establish a remote connection to a virtualized desktop. Using VDI provides enhanced security and better data protection because most of the data processing is provided by servers in the data center rather than on the local device.

10.7.3 Securing Mobile Devices (Demo Video)

Transcript:

In this demonstration, we're going to discuss mobile device security. Specifically, we're going to look at a few things you can do to increase the overall security of an iPad running the iOS operating system.

Let's begin with passcode locks. I'm going to go to Settings, then to Touch ID & Passcodes.
Now, I need to enter my current passcode.
You can use passcodes on your iPad to protect the information stored on the device. If you set a passcode, then every time you either power on the device or wake it up, you will be prompted to enter the passcode before you can run any apps or access any of the information on the device.
That's a really good idea in case you forget this device in a taxicab, hotel, train station, or airport. You don't want just anyone to pick up the device and have full access to whatever's on it.
So, let's look at how you do this. Notice that, right now, passcodes are currently turned on. Let's go ahead and tap Turn Passcode Off, and then we're prompted to confirm that. I'll tap Cancel.
Right below that, I can change the passcode. And when I tap it, the iPad wants to know what my current passcode is before it allows me to change to a new one.
So, that is how you work with passcodes.
In addition, we can also specify how long this device can be idle before we're going to require the passcode to be re-entered. So, first, we need to go to Display & Brightness. And then to Auto-Lock right here. Notice that currently, Auto-Lock is set to Never. That means that this iPad can sit idle forever and the user will not be required to re-enter the passcode.
Let's change that. I'm going to tap on Never. And let's set the auto-lock for 15 minutes. Now, if this iPad sits idle for 15 minutes, meaning I'm not tapping anything, then the screen is automatically going to lock.
So, to this point, we've enabled a passcode, and we've set our screen to automatically lock after 15 minutes. So far, we've increased the security a little bit on this device.
But there are more things we can do. I'll tap Touch ID & Password again. I'll enter in my passcode.

Now scroll to the bottom of this screen. There's an option called Erase Data. If I turn Erase Data on, then all the data on this iPad will be erased if the user tries to enter an incorrect password 10 times in a row. After 10 consecutive failed passcode attempts, all the data on this iPad is going to get erased.
Let's turn that option on. And it warns us, "Hey, if you turn this option on, then everything on this iPad is going to be erased after 10 failed passcode attempts." We're going to go ahead and say, "Nope." I'm borrowing this iPad, so the owner might not like that.
This is a powerful option, and you need to carefully decide whether you want it on. If you have it turned on and someone enters the wrong passcode 10 times in a row, you'll have to restore all the data on this iPad from backup, either from iTunes on a PC using a USB cable or pulling it down from iCloud.
Basically, what we're assuming is that if somebody enters the wrong passcode 10 times in a row, it isn't their iPad. So, at this point, we've really increased the overall security of this device.
Another aspect of mobile device security involves being able to track down a lost device because, well, mobile devices do get lost. They get lost all the time. People leave them on airplanes. They get left in hotels, taxicabs, elevators, and train stations. If this happens, you not only want to protect the data on the device, you also probably want to figure out where that device is.
Many mobile devices provide functionality that you can use to locate the lost device. The iOS operating system running on this iPad provides a function called Find My iPad, and it's tied to the iCloud backup function. If we enable this function and then we lose this iPad, we can sign into iCloud from any web browser on a PC or a laptop system and then use the Find My iPad option to view the device's approximate location on a map.
I tapped iCloud a second ago. Now scroll down a little bit. Notice down here that the Find My iPad option is already turned on. This gives us a lot of options.
For example, you could have a message displayed on the iPad that tells whoever finds it how to get in touch with you. You could even use iCloud.com to go in and remotely change the passcode lock assigned to this device. And if you're really concerned about not losing the data on a lost device, then you can use iCloud.com to perform a remote wipe. Essentially, what we're doing with a remote wipe is assuming that the iPad is lost, that the person who found it has no intention of returning it, and that they may want to get at the information that's stored on it. In this case, you can use iCloud.com to send a remote wipe command to the iPad, which will then restore the iPad to its original factory settings. Any personal information on it, as well as any proprietary sensitive information belonging to your organization, gets wiped out.
If you have this option turned on, it's not a bad idea to come over here, under Backup, and turn on iCloud Backup as well. The idea here is that if you ever do end up performing a remote wipe, or if you end up losing the iPad altogether and never get it back, then you can restore all the data from your old iPad onto a new iPad. Go ahead and tap Cancel for now.
That's it for this demonstration. In this demo, we talked about some things you can do to increase the overall security of a mobile device, in this case, an iPad. We began this demonstration by talking about how to set passcode locks. We talked about how to set the auto-lock feature of the iPad. We talked about wiping the data off the iPad if somebody enters the wrong passcode more than 10 times in a row. Then we ended this demonstration by talking about how to locate a lost device using the Find My iPad option and iCloud.

10.7.4 Secure an iPad (Simulation)

Scenario

You work as the IT security administrator for a small corporate network. The receptionist uses an iPad to manage employees' schedules and messages. You need to help her secure the iPad because it contains all of the employees' personal information.

In this lab, your task is to:

View the current iOS version and then answer the applicable question.

Apply the latest software update and then answer the applicable question.

Configure Auto-Lock with a five-minute delay.

Configure Passcode Lock using a passcode of **C@sp3r**

Require the passcode after five minutes.

Configure Data Erase to wipe all data after 10 failed passcode attempts.

Require unknown networks to be added manually.

Turn off Bluetooth.

Explanation

Complete this lab as follows:

Verify the current version of iOS installed on your iPad.

Select **Settings** .

From the Settings pane, select **General** .

From the General pane, select **About** .

From the top right, select **Answer Questions** .

Answer Question 1. Minimize the question dialog.

Apply the latest software update.

From the About pane's heading, select **General** . This returns you to the General settings.

From the General pane, select **Software Update** .

Select **Download and Install** .

Select **Agree** .

Select **OK** . The software is downloaded.

Select **Install** .

The installation automatically starts after 10 seconds.

Slide the **arrow** to the right to unlock the iPad.

From the top right, select **Answer Questions** .

Answer Question 2 and then minimize the question dialog.

Configure Auto-Lock.

From the Settings pane, select **Display & Brightness** .

From the right pane, select **Auto-Lock** and then select **5 minutes** .

Configure Complex Passcode Lock and Data Erase.

From the left menu, select **Touch ID & Passcode** .

From the right pane, select **Turn Passcode On** .

Enter the new passcode of **C@sp3r**

Select **Next** .

Re-enter **C@sp3r** .

Select **Done** .

Scroll down and then slide ***Erase Data*** to **ON** .

Select **Enable** .

Select **Require Passcode** .

Select **After 5 minutes** .

Require unknown networks to be manually added.

From the left menu, select **Wi-Fi** .

Select ***Ask to Join Networks*** , then select **OFF** .

Turn off Bluetooth as follows:

From the left pane, select **Bluetooth** .

Slide ***Bluetooth*** to **OFF** .

From the top right, select **Answer Questions** .

Select **Score Lab** .

10.7.5 Creating a Guest Network for BYOD (Demo Video)

Transcript:

In this demonstration, we're going to lookÂ at creating a bring your own device (BYOD)Â guest wireless network for employees.Â This can be a very useful if you're anÂ enterprise wireless network administrator.

When employees work for an organization, they expect to beÂ able to have internet access for their personal wirelessÂ devices so they can check social media, email, and so on.
We don't want them to use our standard wirelessÂ network because that would be insecure.Â Instead, we can create an isolated wireless network thatÂ has access to the internet but not our internal network.

We're going to use this particularÂ vendor's wireless networking equipment.Â The way you do it with each vendor'sÂ wireless equipment will be different, butÂ the same general principals apply.
Also keep in mind that your organizationÂ should have a policy in place on how theyÂ want to create their wireless networks.
Before we go too far, we could start configuring some of the things on a different device. For example, we could use our network security device to create a VLAN and handle DHCP for us. It all depends on how your organization wants to configure things and have them managed.
Let's continue.
For this vendor's equipment, what we needÂ to do is define a guest access service for our BYOD.Â Then, we need to create a guest wireless LAN.
The first thing we need to do is click Networks.
We want to choose Create New Network.
On this page we decide on a name. I'll call it BYOD, which stands for bring your own device.
Now we're going to choose Guest for our network type. When we pick Guest, that network will be preconfigured with certain rules and policies to help protect our other networks.
Next, we're going to specify that this network will be VLAN 50. This tags the traffic so that our other network equipment knows how to handle it.
Now we need to specify the IP for the BYOD network. I'm going to give it an IP of 192.168.50.1 with a /24 subnet. This can be anything you want, but I like to name things to correlate with the VLAN. So, in this case I made the third octet 50 to match the VLAN. You don't have to, it's just something I do to help me remember that when I see addresses with 50 dot something, it's VLAN 50. This is a Class C private IP range and it'll give us 254 IP addresses that we can use. When I hit Enter, it populated some other settings automatically for me. I have the gateway, the broadcast IP, total IP count, the range, and my subnet mask.
I'll scroll down a bit and then come over here and click on Update DHCP Range. This populates a suggested range of addresses that I can use for my DHCP and hand out to the guest. It put in 50.6 to 50.254, which is fine with me. By the way, I do like to leave a few addresses at the beginning of my networks for potential static assignments. So this worked out well.
I'll scroll down a bit more and now let's look at our DHCP lease time. By default, it's set to 86,400 seconds. For those of you who don't like math, that's 24 hours. Now, I might want to shorten that. If this is an office setting, perhaps 10 hours is plenty. Just do the math and change the number of seconds to satisfy your lease time preference.
My DHCP Gateway is set to automatic. If my Gateway were something different, I could change it, but I'm using the default here.
I also have some various Advanced DHCP Options but there's nothing here that we need to configure. Just be aware that you do have some additional options if your organization happens to need them.
I'll click on Save here and go to the next step.
Now that we have our network, we now need to create a wireless network. To do that, I go to Wireless Networks.
I have a regular wireless network called CorpNet but I don't want this being used for personal devices. So I'll create a new one for that. I click on Create Wireless Network.
The first thing is to give it a Name or SSID. For that I just name it BYOD to stay consistent. I'll leave it Enabled.
By default it's set to be an Open network This is probably not a good idea since the traffic won't be encrypted and others on that network could easily have their traffic captured. I'll change this to WPA Personal and put in a security key here that my BYOD guest will use.
I'll check Guest Policy. This will enable extra security options such as dropping broadcast traffic from users' wireless connections. It's recommended that you check this.
Down here I said that we were using VLAN 50. This is where we put that in.
I'm not going to change any of the other settings. We have Rate and Beacon Controls, MAC Filtering, and we can configure RADIUS MAC Authentication. Once again, we won't configure any of this.
I'll click on Save.
So here you can see I have my BYOD wireless network in addition to my other wireless network.
Now let's look at Guest Control. I'll click on it and here I can see our settings.
First thing is to check the box to Enable Guest Portal.
Here I can decide what sort of authentication I might want to use. It's set to No authentication. I'll leave it set to the default.
I can choose how long someone has access before it times out. 8 hours is set by default but I can change that if I want to.
We can use the default landing page our BYOD guest will go to or have it redirected for them.

We have other settings such as creating a welcome message or displaying Terms of Service for those using our network.
We can customize the portal. This is what the BYOD guest sees when they connect. I can preview what the mobile users see as well, such as what they see on a notebook or desktop system. I can create a custom background image or custom logo and upload them instead of the default ones provided. I have all sorts of things I can change, like text, color, and so on.
For Access Control, I can decide what users have access to as soon as they connect as well as after they connect. I currently have three default networks that they're not able to access from the Guest network. I can add other networks if needed, or actually allow them access. I won't make any changes to this.
I'll click on Apply Changes.
The last thing I want to look at is User Groups. I'll start by clicking on Create New User Group. For name I'll put in BYOD. Now what we're doing here is limiting our users to the amount of bandwidth they're allowed to use. I'm sure you've been to public places and done a speed test only to find that the speed is horrible. Well, this is where the person responsible does this to you. Being greedy with my bandwidth, I'm only going to give my BYOD guests 5 Mbps for download. For upload I'm only going to give them 2 Mbps.
I'll click save and you can see the results. By the way, the default is unlimited bandwidth. That's whatever the max is. That's it for this demonstration.Â In this demo, we createdÂ a guest wireless network where users who bring their own devices can connect to the internet.

10.7.6 Create a Guest Network for BYOD (Simulation)

Scenario

You are a network technician for a small corporate network. You need to enable BYOD Guest Access Services on your network for guests and employees with mobile phones, tablets, and personal computers.

In this lab, your task is to perform the following:

Access the Wireless Controller console through Google Chrome at **http://192.168.0.6** .

Username: **admin** (case sensitive)

password: **password**

Set up Guest Access Services using the following parameters:

Name: **Guest_BYOD**

Authentication: **Use guest pass authentication**

The guest should be presented with your terms of use statement and allowed to go to the URL they were trying to access.

Verify that **192.168.0.0/16** is on the list of restricted subnets.

Create a guest WLAN using the following parameters:

Network name: **Guest**

ESSID: **Guest_BYOD**

Type: **Guest Access**

Authentication: **Open**

Encryption Method: **None**

Guest Access Service: **Guest_BYOD**

Isolate guest wireless clients from other clients on the access point.

Open a new Google Chrome window and request a guest pass using the BYODAdmin user as follows:

URL: **192.168.0.6/guestpass**

Username: **BYODAdmin** (case sensitive)

Password: **P@ssw0rd** (0 is a zero)

Use any ***full name*** in the Full Name field.

Make a note of or copy and paste the key in the Key field.

If you are using the Firefox browser, copying and pasting the key will not work. Make a note of the key value and type it into the Key field.

Use the key from the guest pass request to authenticate to the wireless LAN Guest_BYOD from the Gst-Lap laptop computer in the Lobby.

Explanation

Complete this lab as follows:

Access and log into the Ruckus **ZoneDirector** .

From the taskbar, select **Google Chrome** .

In the URL field, enter **192.168.0.6** and then press **Enter** .

Maximize the window for better viewing.

In the Admin field, enter **admin** (case sensitive).

In the Password field, enter **password** as the password.

Select **Login** .

Set up Guest Access Services.

Select the **Configure** tab.

From the left menu, select **Guest Access** .

Under Guest Access Service, select **Create New** .

Change the Name field to **Guest_BYOD** .

For Terms of Use, select **Show terms of use** .

Expand **Restricted Subnet Access** .

Verify that **192.168.0.0/16** is listed.

Select **OK** .

Create a Guest WLAN.

From the left menu, select **WLANs** .

Under WLANs, select **Create New** .

Change the Name to **Guest** .

Change the ESSID to **Guest_BYOD** .

Under Type, select **Guest Access** .

For Wireless Client Isolation, select **Isolate wireless client traffic from other clients on the same AP** .

Select **OK** .

Close **Google Chrome** .

Request a Guest password.

Open a new **Google Chrome** browser window.

In the URL field, enter **192.168.0.6/guestpass** and then press **Enter** .

Maximize the window for better viewing.

In the Username field, enter **BYODAdmin** (case sensitive).

Enter **P@ssw0rd** as the password (0 is a zero).

Select **Log In** .

In the Full Name field, enter any ***full name*** .

In the Key field, highlight the ***key*** and press **Ctrl + C** to copy the key.

If you are using the Firefox browser, copying and pasting the key will not work. Make a note of the key value and type it into the Key field.

Select **Next** .

Access the wireless Guest Access Service from the guest laptop in the lobby.

From the top left, select **Floor 1** .

Under Lobby, select **Gst-Lap** in the lobby.

In the notification area, select the wireless **Network** icon.

Select **Guest_BYOD** .

Select **Connect** .

Select **Yes** .

After Chrome opens to the Guest Access login page, paste the ***key*** from the Key field.

Select **Log In** .

10.7.7 Practice Questions (Section Quiz)

q_boyd_sec_aup_01_secp8

Which of the following is a policy that defines appropriate and inappropriate usage of company resources, assets, and communications?

Answers:

***Acceptable use policy (AUP)**

Business impact analysis (BIA)

Disaster recovery plan (DRP)

Business continuity plan (BCP)

Explanation:

An acceptable use policy (AUP) is a policy that defines appropriate and inappropriate usage of company resources, assets, and communications.

A business impact analysis (BIA) identifies critical processes and assets and the effect of their loss on the company.

A disaster recovery plan (DRP) addresses how a corporation should respond to a disaster.

A business continuity plan (BCP) addresses how a corporation responds to the disruption of critical systems.

q_boyd_sec_aup_02_secp8

Which of the following BEST describes an acceptable use agreement?

Answers:

***An agreement that identifies employees' rights to use company property, such as internet access and computer equipment, for personal use.**

An agreement that prohibits an employee from working for a competing organization for a specified period of time after he or she leaves the organization.

An agreement that outlines the organization's monitoring activities.

A legal contract between the organization and the employee that specifies that the employee is not to disclose the organization's confidential information.

Explanation:

An acceptable use agreement identifies employees' rights to use company property, such as internet access and computer equipment, for personal use.

A non-compete agreement prohibits an employee from working for a competing organization for a specified period of time after he or she leaves the organization.

An employee monitoring agreement outlines the organization's monitoring activities.

A non-disclosure agreement is a legal contract between an organization and an employee that specifies that the employee is not to disclose the organization's confidential information.

q_boyd_sec_aup_03_secp8

Your organization allows employees to bring their own devices into work, but management is concerned that a malicious internal user could use a mobile device to conduct an insider attack.

Which of the following should be implemented to help mitigate this threat?

Answers:

Implement a network access control (NAC) solution.

Implement an AUP that specifies which apps are allowed for use with organizational data.

Implement a guest wireless network that is isolated from your organization's production network.

***Implement an AUP that specifies where and when mobile devices can be possessed within the organization.**

Explanation:

To mitigate the threat of an insider attack, you should consider implementing an AUP that:

Specifies where and when mobile devices can be possessed within the organization. For example, the possession of mobile devices may be prohibited in high-security areas.

Notifies users that personally owned devices are subject to random searches if brought on site.

A network access control (NAC) solution would not help mitigate an insider attack with mobile devices.

Implementing an acceptable use policy (AUP) that specifies which apps are allowed for use with organizational data would not help mitigate an insider attack with mobile devices.

Implementing a guest wireless network that is isolated from your organization's production network would not help mitigate an insider attack with mobile devices.

q_boyd_sec_byod_secp8

Which of the following could be an example of a malicious insider attack?

Answers:

A user has lost a company-owned device.

A user's device has become infected with malware.

A user has not implemented appropriate security settings.

***A user uses the built-in microphone to record conversations.**

Explanation:

If a user is so inclined, he or she could use their mobile device to conduct a malicious insider attack. For example, they could:

Use the built-in camera, which nearly all modern mobile devices have, to take pictures of sensitive internal information.

Use the built-in microphone to record conversations.

Use the built-in video function to record proprietary processes and procedures.

Use the device's mobile broadband connection to transfer stolen data to parties outside the organization, bypassing the organization's network security mechanisms.

If a user copies sensitive data to their device, the organization could potentially lose control of that information. Even the question of who owns the data after it has been copied to a personal device becomes problematic. Consider the following scenarios:

A user may not have implemented appropriate security settings on their device, allowing anyone who gains access to the device to view sensitive data.

A user may lose the device, allowing anyone who finds it to access sensitive data.

A device may become infected with malware, potentially exposing sensitive data.

q_boyd_sec_cope_secp8

Which device deployment model gives businesses significant control over device security while allowing employees to use their devices to access both corporate and personal data?

Answers:

BYOD

CYOD

***COPE**

VDI

Explanation:

The corporate-owned personally enabled (COPE) model gives businesses significant control over device security while allowing employees to use their devices to access both corporate and personal data. Because the company owns the device, it can be secured more easily and wiped clean if lost or stolen. One disadvantage of this model is that employees who are not free to choose their own devices may end up bringing their own anyway.

The bring your own device (BYOD) model has users bringing in their personal devices and using them for business use.

The choose your own device (CYOD) model provides slightly more flexibility in giving users a limited selection of devices to choose from.

A virtual desktop interface (VDI) can be used with any device deployment model. A VDI allows mobile devices to establish a remote connection to a virtualized desktop.

q_boyd_sec_device_disconnect_secp8

You are the IT Security Manager at a mid-sized company. The company has recently adopted a bring your own device (BYOD) policy.

One of your employees, John, has been using his personal device for work-related tasks. John's device gets infected with malware, which he unknowingly connects to the company's network. As a result, the malware spreads across the network, compromising sensitive data.

As the IT Security Manager, what should be your immediate course of action?

Answers:

Ignore the issue as it's John's personal device and not the company's responsibility.

***Disconnect John's device from the network, isolate the affected systems, and start an investigation to understand the extent of the damage.**

Immediately fire John for causing a security breach.

Publicly blame John for the incident to set an example for other employees.

Explanation:

Disconnecting John's device from the network is the most appropriate response. Disconnecting John's device will prevent further spread of the malware. Isolating the affected systems will help contain the malware and prevent it from infecting other systems. Starting an investigation will help you understand the extent of the damage and how the malware was able to infect the network, which can inform future prevention strategies.

Ignoring the issue will not solve the problem. The malware could continue to spread and compromise more systems and data. As the IT Security Manager, it's your responsibility to ensure the security of the company's network and data, regardless of the source of the threat.

While John's actions led to a security breach, firing him immediately is not the best course of action. It's important to investigate the incident thoroughly to understand how it happened. It's also crucial to provide training to employees about the risks and responsibilities associated with the BYOD policy to prevent similar incidents in the future.

Publicly blaming John could create a negative work environment and may not necessarily prevent future incidents. Instead, use this incident as a learning opportunity for all employees. Provide training on the proper use of personal devices for work-related tasks and the potential security risks associated with them.

q_boyd_sec_mdm_secp8

Users in the sales department perform many of their daily tasks, such as emailing and creating sales presentations, on company-owned tablets. These tablets contain sensitive information. If one of these tablets is lost or stolen, this information could end up in the wrong hands.

The chief information officer wants you to implement a solution that can be used to keep sensitive information from getting into the wrong hands if a device is lost or stolen.

Which of the following should you implement?

Answers:

***A mobile device management (MDM) infrastructure**

A network access control (NAC) solution

An acceptable use policy (AUP)

A guest wireless network that is isolated from your organization's production network

Explanation:

A mobile device management (MDM) infrastructure, such as Microsoft Intune, can be used to wipe data clean from a device that has been lost or stolen.

A network access control (NAC) solution can remediate devices before allowing them to connect to your network.

An acceptable use policy (AUP) can be used to define which kind of data is allowed on personally owned devices and which kind of data is prohibited.

A guest wireless network that is isolated from your organization's production network allows user-owned devices to gain internet access, but it quarantines them from the rest of your organization's production network.

q_boyd_sec_nac_01_secp8

If a user's BYOD device (such as a tablet or phone) is infected with malware, that malware can be spread if that user connects to your organization's network. One way to prevent this event is to use a network access control (NAC) system.

How does an NAC protect your network from being infected by a BYOD device?

Answers:

***The NAC remediates devices before allowing them to connect to your network.**

The NAC forces BYOD devices to connect to a guest network that is isolated from your production network.

The NAC specifies which apps can be used while the BYOD device is connected to the organization's network.

The NAC notifies users that personally owned devices are subject to random searches if brought on site.

Explanation:

The NAC remediates devices before allowing them to connect to your network. This means that the NAC performs the following types of device management tasks before allowing a device to connect to the network:

Operating system updates

App updates

Anti-malware installation

Anti-malware definition updates

An alternative to using an NAC solution is to force BYOD devices to connect to a guest network that is isolated from your production network.

An acceptable use policy (AUP) specifies which apps can be used while the BYOD device is connected to the organization's network.

An AUP also notifies users that personally owned devices are subject to random searches if brought on site.

q_boyd_sec_nac_02_secp8

The IT manager has tasked you with implementing a solution that ensures that mobile devices are up to date, have anti-malware installed, and have the latest definition updates before being allowed to connect to the network.

Which of the following should you implement?

Answers:

BYOD

MDM

***NAC**

VDI

Explanation:

A network access control (NAC) solution can remediate devices before allowing them to connect to your network. This includes defining that a device is fully updated, has anti-malware installed, and has the latest definition updates.

The bring your own device (BYOD) model has users bringing in their personal devices and using them for business use.

A mobile device management (MDM) infrastructure, such as Microsoft Intune, can be used to track, manage, and even remotely wipe a user's mobile device.

A virtual desktop infrastructure (VDI) can be used with any device-deployment model. A VDI allows mobile devices to establish a remote connection to a virtualized desktop.

q_boyd_sec_wifi_secp8

Users in the sales department perform many of their daily tasks, such as emailing and creating sales presentations, on their personal tablets.

The chief information officer worries that one of these users might also use their tablet to steal sensitive information from the organization's network. Your job is to implement a solution that prevents insiders from accessing sensitive information stored on the organization's network from their personal devices while still giving them access to the internet.

Which of the following should you implement?

Answers:

A mobile device management (MDM) infrastructure

A network access control (NAC) solution

An acceptable use policy (AUP)

***A guest wireless network that is isolated from your organization's production network**

Explanation:

A guest wireless network that is isolated from your organization's production network allows user-owned devices to gain internet access, but it quarantines them from sensitive information on your organization's production network.

A mobile device management (MDM) infrastructure, such as Microsoft Intune, can be used to wipe data from a device that has been lost or stolen.

A network access control (NAC) solution can remediate devices before allowing them to connect to your network.

An acceptable use policy (AUP) can be used to define which kind of data is allowed and prohibited on personally owned devices.

q_boyd_vs_cyod_secp8

At a large tech company, the IT department explored options to accommodate employees who prefer using their own devices for work purposes. The management understands that embracing such a policy can improve productivity and job satisfaction.

They consider two strategies: bring your own device (BYOD) and choose your own device. The IT team evaluated the benefits and risks associated with each approach.

Which of the following statements about BYOD and CYOD are correct? (Select two.)

Answers:

***Bring your own device allows employees to use their personal devices for work purposes.**

***Choose your own device limits device choices to a predefined list of approved options.**

Choose your own device provides employees with the freedom to select any device for work, regardless of security concerns.

Bring your own device and choose your own device have the same level of control and management by the IT department.

Bring your own device (BYOD) allows businesses to purchase devices at significant discounts.

Explanation:

Bring your own device (BYOD) policy permits employees to utilize their devices, such as smartphones or laptops, for work tasks. This approach can increase employee satisfaction and flexibility but may pose security challenges if not properly managed.

Choose your own device (CYOD) allows employees to select their work devices from a preapproved list. This strategy offers a balance between employee choice and IT control.

CYOD allows employees to choose from a predetermined list of approved devices, ensuring better security and compliance with organizational policies.

BYOD involves managing personal devices that may vary in models and security configurations, whereas CYOD focuses on a limited set of approved devices, making management more structured and controlled.

Corporate-owned devices is an alternative to BYOD and CYOD. A corporate-owned device strategy lets businesses more effectively monitor and control activities performed on mobile devices. One advantage of this model is that businesses can purchase devices at significant discounts.

10.8 Embedded and Specialized Systems

As you study this section, answer the following questions:

How can you minimize the damage of compromised embedded devices?

What are common static environments within the Internet of Things (IoT)?

In this section, you will learn to:

Configure smart home devices.

The key terms for this section include:

Term	Definition
Supervisory control and data acquisition (SCADA)	SCADA is an industrial computer system that monitors and controls a process.
Internet of Things (IoT)	The network of physical devices such as vehicles, home appliances, etc., that are embedded with electronics, software, sensors, actuators, and connectivity that enable them to connect, collect, and exchange data through the internet.
Arduino	Arduino is an open-source hardware and software platform for building electronic projects.
Raspberry Pi	Raspberry Pi is a low-cost device the size of a credit card that's powered by the Python programming language. It's manufactured into a single system on a chip (SoC).
Field Programmable Gate Array (FPGA)	FPGA (Field-Programmable Gate Array) is a reconfigurable integrated circuit that can be programmed to perform various tasks and functions.

Subscriber identity module (SIM) card	A SIM card encrypts data transmission and stores information.
Zigbee	Zigbee is a radio protocol that creates low-rate private area networks.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.4 Explain the importance of using appropriate cryptographic solutions. Tools Trusted Platform Module (TPM) 2.2 Explain common threat vectors and attack surfaces. Unsecure networks Wireless Wired Bluetooth 3.1 Compare and contrast security implications of different architecture models. Architecture and infrastructure concepts IoT Industrial control systems (ICS)/supervisory control and data acquisition (SCADA) Real-time operating system (RTOS) Embedded systems 3.3 Compare and contrast concepts and strategies to protect data. Methods to secure data Encryption

	4.1 Given a scenario, apply common security techniques to computing resources. Hardening targets Mobile devices ICS/SCADA Embedded systems IoT devices Mobile solutions Cellular Wi-Fi Bluetooth

10.8.1 Embedded and Specialized Systems (Lesson Video)

Transcript:

Today's smart technology is being embedded into devices like TVs, kitchen appliances, environmental controls, and even industrial equipment. And it's becoming increasingly common. These devices are sometimes referred to as static environments because they weren't designed to be customized or modified in any way by you, the network administrator.

Smart tech history is connected with supervisory control and data acquisition systems. We just call them SCADA. This infrastructure manages automated factory equipment that relies on the smart technology embedded in modern devices. As its name suggests, SCADA systems provide two general functions: supervisory control and data acquisition. The first controls remote equipment over a network connection. The second gathers information from those remote devices, allowing you to monitor their status.
Using network connectivity, SCADA systems can manage industrial equipment a long distance away from a control center. This is sometimes called a distributed control system, or DCS. To make this work, SCADA systems have several different components. First, there's a central supervisory computer that communicates with and sends control commands out to connected SCADA devices. The devices have remote terminal units, or RTUs. The RTUs connect the equipment to the network, which enables them to receive commands from the supervisory system and then send status information back.
Alternatively, SCADA equipment might have programmable logic controllers, or PLCs, installed. PLCs connect the SCADA equipment to the network just like RTUs. The difference is that they're usually less expensive.
Another important component is the type of network link used to connect the supervisory computer to the RTUs or PLCs. Some of the most common options include a standard internet connection, a satellite link, a private WAN link, or even a simple modem connection over a telephone line.
When talking about smart technology and SCADA, we can't forget the Internet of Things, or IoT.
IoT is a natural extension of SCADA. Its evolution is such that late-generation SCADA systems developed into first-generation IoT systems. An IoT ecosystem is made up of web-enabled smart devices that use embedded processors, sensors, and communication hardware to collect, send, and act on data they gather from their environments.
One important aspect of newer IoT devices is the operating system they use because these offer connectivity, usability, and interoperability.

One of these operating systems is called RIOT OS. It requires few resources and is very energy efficient. It's used on embedded systems, actuator boards, and sensors.
Another is ARM Mbed OS. This OS is primarily used with low-power technology such as wearable devices. In other words, any mobile device that's meant to be worn somewhere on the body. These
devices can be as simple as a step-tracking wristband or as complex as a virtual reality headset. Most wearable devices are designed to interface with another device.
For example, a smartwatch by itself has a limited set of functions. But when you connect it to a smartphone through Bluetooth, you get added functionality like text messaging or being able to answer phone calls.
Back to the operating systems now. RealSense OS X is used in Intel's depth-sensing technology for cameras and sensors. Then there's Nucleus and Integrity RTOS, which are both used for aerospace, industrial, automotive, and medical devices. When it comes to drones and robots, Ubuntu Core or Snappy are usually preferred.
Whether it's a tablet, smartphone, or an e-reader, all mobile devices share some characteristics. The most common is the power source. The power source is typically a lithium ion battery rated in milliamp hours. The larger the number, the greater the battery capacity. For example, the average smartphone battery is about 2,000 milliamp hours while a notebook battery is about 6,000 milliamp hours.
Another characteristic is a mobile device's storage.
To extend battery life, mobile devices use some sort of non-volatile flash memory to store information. Because no moving parts need to be powered, flash memory is a more energy-efficient storage medium. In addition, a lot of mobile devices have expandable storage in the form of micro-SD cards. This allows mobile devices to increase their storage to upwards of 200 gigabytes.
Mobile devices need connectivity to the internet and to other mobile devices. To do this, they use a variety of wireless connection mediums. For example, the typical smartphone utilizes 802.11, Bluetooth, and cellular wireless technologies.
Mobile devices also have internal sensors that collect environmental data, usually with a GPS chip. They use these chips to calculate the device's location information, which you can use for navigation and for finding your device if you happen to lose it.
Another internal sensor is called an accelerometer. This is a sensor that detects movement on a single plane, typically the horizontal plane. It detects when a mobile device is turned sideways and tells the device to change the screen's orientation.
A third sensor is a gyroscope. It also detects movement, but instead of detecting movement on a single plane, it detects horizontal and vertical movements. If you've ever played a game on a smartphone or tablet that requires you to tilt the device, you've used a gyroscope.
A key issue with smart technology is that there's little to no ability to modify the technology within. As a result, it's very difficult to manage security. For example, you can't install anti-malware software on a smart refrigerator or on an HVAC system even though there are significant security risks associated with them.
For example, in early 2014 the first documented IoT attack occurred. This attack leveraged smart devices to conduct a rather pervasive, malicious email-phishing exploit.
The trouble is that because smart devices are becoming more commonplace, we tend to forget about them. In addition, smart device vendors are slow to protect their products proactively because of cost constraints. For this reason, it's even more important for you as an administrator to secure your network against any possible smart device attacks.
It's also good to keep physical security in mind. When an attacker discovers a rogue access point, they're able to run various types of vulnerability scanners from outside the company. But if they gain physical access, they can hide a physical rogue access point as well. This is often done by configuring an extremely compact and powerful hardware device called a Raspberry Pi.
Just like smart device attacks, a rogue access point attack happens simply because a network administrator didn't properly configure the legitimate access points. Maybe he or she didn't implemented proper security measures in the beginning and eventually just forgot about them altogether. This is known as access point misconfiguration.
To defend against these attacks, there are a few things you can do. First, have a solid firewall design in place. Second, have intrusion detection. Or better yet, install intrusion-protection devices. Third, have very strong organizational security policies in place so that you're not caught off guard.
That's it for this lesson. In this video, we looked at security risks associated with embedded and specialized systems. We talked about SCADA, IoT, smart devices, and mobile devices. We talked about the security risks associated with these devices as well as with Raspberry Pi. We ended this lesson by talking about how you can defend yourself from distributed attacks leveled against these smart devices.

10.8.2 Smart Home (Demo Video)

Transcript:

Everyone seeks convenience and connectivity whether you are at work, home, in the car or wherever. Smart devices are showing up nearly everywhere. It could be your thermostat, light switches, light bulbs, electrical plugs, security cameras, door locks, sprinkler systems, and even digital speakers such as Google Home or Amazon Echo.

There are hundreds of these devices and more coming on the market all the time. It would be simply impossible to cover all of them, but we are going to take a look at a few of them in this demo.
The first one, and one of the very popular, is the Amazon Echo. The Echo is a smart speaker that is controlled by voice. It responds to voice commands when you use a "wake word," which is normally Alexa.
The device is capable of doing things such as playing music, making a to-do list, setting alarms, providing weather info, along with all sorts of other things. It can also be used in conjunction with other smart devices to control devices such as lights, security cameras, and so on. One of my favorite things to do at home is to use Bluetooth to pair Alexa with my surround sound system and stream music.
Most smart devices are managed with an app and the Echo is no different. Let's take a look at the Amazon Echo app on an Android Device. Here is a Google Pixel phone and I have my Amazon Alexa app on it. Let's go ahead and open it.
The first thing I can see are some things to try, followed by some of the recent things that it has done. As you can see, we have some music lovers that use the Echo.
Let's go up to our menu and then down at the bottom. We will tap on our settings. When we do that, we get a new screen. The first thing we can look at is the Alexa account. Here we do things such as train Alexa to recognize our voice. Perhaps we have an accent and want to train Alexa to recognize it better.
Below that, we can tell Alexa that it is OK to use voice commands to purchase items. If we go into that, we can see that we can require a code confirming the purchase of items. If that was not the case, I could see some issues with impulse shopping. Let's go back.
Next is the Alexa Voice Responses. Alexa is configured to respond in short replies which is the default.
The Amazon Household is a feature to allow other users to use this device to do things such as purchase products and services, using the Voice Purchasing feature.
Below that is History. Here you can see a list of things that Alexa has been asked to do. As you can see it can be quite detailed. Although you must use the "wake word" first, some feel that these smart speakers, may be listening to us a little too much at times.
The last selection will take you to the Amazon website where you can view more history items, frequently asked questions, the privacy notice, and the terms of use for the device.
The Echo can work with other smart devices. Let's tap down here on the lower right on the Smart Devices Icon.
The first thing we have is the Echo & Alexa group. If I tap on that, you can see that I have a couple of Echo's connected. If I tap on the first one, Dana's Echo, you can then see some addition information such as connected devices, the Wi-Fi information, and so on. Let's go back a couple of screens.
Next, we have Lights. This is a smart light located on the front door of my home. If I look at it, I can see that currently that light is on. If I tap it, it will go off. If I tap the icon below, Create a Routine, I could configure this light to come on at night and go off during the day. Now for this to work with this Echo, I had to use the Set this up on the app that came with the light, in order for this to work.
I'm going to go back a few screens and tap on Plugs. This is for a smart plug that is in our home and connected to a lamp. When I tap this here, I can turn this lamp off or on. This is also configured to work with voice commands. I can say, "Alexa, light off." And she would turn that light off.
If I tap on the Lamp, I can once again see that at the bottom I can tap here to create a routine for this plug to come off or on, either at certain times or use specially configured voice commands to do so.
Now, we saw how the smart plug was connected and we had a lamp plugged into it. Let's take a look at that app and see how that is configured. I'll exit my Amazon Echo app and go into my Smart Plug app.
OK, we are in our app and here you can see that I have one smart plug and I named it Lamp. From this app, I can turn the plug, which the lamp is plugged into, off and on. The button is green letting me know that it is now on.
If I had other smart devices from this manufacturer, they would be listed here. To add a device, I would tap the plus icon up here, and here we can see a list of all the different types of devices that I would be able to add. I don't have any additional devices but if I did, I would tap the type of device and this app would walk me through the installation and setup.
For example, if I had a smart bulb, I could just tap here. You can see that it tells me what to do. I don't have any of these, so I'll back out of here.

Finally, if I tap on the selection, Works with Kasa, I can see some of the other smart devices that are compatible with this device. You can see Amazon Alexa in this list. As we saw earlier, this smart plug works with my Amazon Echo.
The final thing we will look at are some security cameras. Once again, the manufacture uses a mobile device app to setup and configure the security cameras. The app is also used to view the video clips.
Now this system has three cameras set up and configured. Each one can be configured individually by tapping these setting next to the main icon. Here you can name each camera and check it's battery life. This system uses batteries, so they can be installed anywhere, as long as it can get my Wi-Fi signal.
It also shows me the temperature where the camera is mounted and if the camera is enabled or not. The retrigger time is the amount of time between the time it first senses motion and when I want it to start recording again a second or third time. I have this set to 10 seconds.
Since the street is in view of the camera and we have cars going by occasionally, I don't want it picking up every single car, so I have the sensitivity set to 3. Only large vehicles from the street set off this camera, but it still picks up anything that comes in the front yard.
The clip length is set to 25 seconds. If there is more motion after that, the camera will retrigger and record for another 25 seconds. However, below that you can see that the clip will end early if the motion stops.
As I scroll down, you can see other settings, Infrared Illuminator, video quality, if the camera is enabled, latest update, the Wi-Fi signal to the camera, and the camera to the sync module, which is located next to the wireless router. Let's go back a screen.
With this particular system, this top view is an image of what I'm looking at, not a live view. Since these run on battery, they are not always recording video, only on motion or if I tap the video camera icon over here on the left. When I do, it takes me to a live video stream of the camera. You can see that it's at night and I have a skeleton riding a bike next to my house.
OK, that's it for this demo. In this demonstration, we talked about smart devices. We looked at few common smart home devices. First, we looked at the Amazon Echo, then we looked at a smart plug and how that is able to work with the Echo. We ended with a quick overview of a home security camera system.

10.8.3 Constraints and Security of Embedded Devices (Lesson Video)

Transcript:

Embedded systems are usually dedicated to performing a precise function. They can vary in size, complexity, and function and can range from tiny, portable devices like smart watches to large traffic controllers. Some have low complexity, like a single micro-controller chip that opens and closes a gate, and some have very high complexity, like the embedded systems in an automated aircraft.

Nowadays, devices are becoming more intelligent and capable than ever. Manufacturers are always competing to be the first to release the latest and greatest device. But in the process of beating their competitors to market, many end up neglecting some of the most important security issues. These circumstances make it so devices are often sent out unchecked and undertested, making them easy for hackers to exploit.
In this lesson, I'll go over some of the security constraints that affect modern embedded devices.
Smart devices collect data for many reasons, such as improving efficiency, experience, and decision-making. Again, the problem is that some devices lack the most basic security and data-protection policies. Because you're dealing with sensitive information, you absolutely have to store and process data securely across your network. This means that you should redact sensitive data before you store it. An alternative is to use data separation to decouple personally identifiable information from data payloads. Data that isn't useful anymore should be disposed of in a safe manner. No measure is ever fail-proof, and every device needs regular patches to address attacks that uncover new flaws.
Patching has its downsides as well, and many times a patch ends up causing just as many problems as it was intended to solve. First of all, the patch might break the device's functionality. Second, most manufacturers are more concerned with producing and releasing products faster than their competition than mitigating security risks. Third, manufacturers often stop releasing patches and support for devices once they start working on a different product. Fourth, many devices use unsupported legacy Linux kernels.
Ideally, each device should undergo proper testing before it's released to the market, and patches should happen on a regular basis. But, sometimes the cost to go through all the testing is more than manufacturers are willing to spend. Many times, they simply accept the risks, even though skipping these important steps is bad for customers and

manufacturers. After all, it only takes one large-scale data breach for a company to lose sensitive information, the public's trust, and maybe their entire fortune.
For this reason, you should always implement secure authentication for users and apps. Authentication is an area that's often overlooked in embedded-technology development. The Mirai botnet was one of the biggest and most troublesome DDoS attacks in recent history. This attack was so successful because it found vulnerable IoT devices and used default usernames and passwords to log in and infect them.
Although almost all devices have to authenticate before they access a network, many allow easy-to-guess default passwords. The main problem is that there's no set regulation for smart devices that companies are legally forced to abide by. With this in mind, some ways to strengthen your own authentication practices are to use two-factor authentication, enforce strong passwords, and use certificates.
Even if you secure your devices with authentication, there's another vulnerability called lack of encryption. Data encryption and decryption is an ongoing process. Most network sensors aren't capable of supporting this process, which means that most data is transferred and received as cleartext. In addition, ports listening to the internet are many times left open continuously. Both factors make data extremely vulnerable to theft, breaches, and other malicious acts.
In order to try to standardize platforms and create trust in the embedded world, a group of experts got together in 2003 and created the Trusted Computing Group, or TCG. Together, they released a standard called Trusted Platform Module, or TPM. Although trust and security are often spoken of as one and the same, they're actually quite different.
Consider the fact that a secure system that can be bypassed without detection isn't trustworthy. At the same time, a trusted system with undiscovered vulnerabilities isn't secure.
To be trusted, a system must behave as expected and be able to detect that something is wrong. That's why TPM is so valuable to trusted computing. It provides essential services such as strong identity, secure storage, and integrity measurement.
That's it for this video. As embedded devices grow and develop, they become more susceptible to exploitation from hackers and other bad actors. Understanding the present challenges in the world of embedded devices can help you protect your data and stand out in your technological career.

10.8.4 Communication of Embedded Systems (Lesson Video)

Transcript:

Now that we have a better understanding of embedded systems, it's time to dive deeper into the technologies and protocols that allow them to communicate.

Embedded systems often require new technologies, and their biggest obstacle is the lack of capable support. For this reason, they currently use standard networking protocols. These protocols are divided into four categories: short-range, medium-range, long-range, and wired.
There are several short-range protocols and technologies. Near-field communication, or NFC, and radio-frequency identification, or RFID, are two very simple, low-energy, and versatile protocols. RFID uses two-way radio transmitter receivers to identify and track object tags. NFC uses magnetic field induction to communicate between mobile and standard electronic devices.
Bluetooth Low Energy, also known as BLE or Bluetooth Smart, is a wireless personal area network. It supports low-power, long-use IoT technology. It's used in the healthcare, security, entertainment, and fitness sectors.
Light-Fidelity, or Li-Fi, is very similar to Wi-Fi. The two key differences are speed and mode of communication. Unlike Wi-Fi, Li-Fi is a visible light communications system. It uses light bulbs to transfer data at the high speed of 224 gigabits per second.
Quick Response, or QR, codes and barcodes are tags attached to products. They're machine-readable and contain information about the product. A QR code is two-dimensional, and you can scan it using a smartphone, while barcodes come in one-dimensional or two-dimensional code.
Thread, Zigbee, and Z-Wave are all radio protocols that create low-rate private area networks. Their advantage is that, although they're low-power, they offer high throughput. Thread uses an IPv6-based networking protocol. Zigbee is a short-range communication protocol based on the IEEE 203.15.4 standard. Z-Wave is a low-power, short-range communication protocol designed mostly for home IoT systems.
Wi-Fi is commonly implemented in wireless local area networking. The most common Wi-Fi standard is 802.11n with a maximum speed of 600 Megabits per second and a range of about 50 meters.

Wi-Fi Direct uses peer-to-peer communication without a set wireless access point. The devices in Wi-Fi Direct only start communicating after an access point device has been selected within the system.
You can also use hotspots to provide wireless network access.
Mobile hotspots let you connect a device to the internet through a portable wireless device such as a phone.
Hotspots form an on-the-spot Wi-Fi network, allowing you to connect a number of gadgets for simple, fast internet access. Hotspots often use third-, fourth-, and fifth-generation technology to provide this type of connection. 5G is the best of them because it achieves speeds twenty times faster that 4G; its peak speed is 20 gigabytes per second. It uses LTE for wireless connections and includes lower frequencies than previous generations, down to 600 Megahertz.
There are two main protocols in the medium-range category, HaLow and LTE-Advanced. HaLow is a branch of Wi-Fi with extended range. It's most useful in rural areas because it uses low data rates, so it reduces power and cost for transmission. LTE-Advanced is a mobile communication. It makes standard LTE better because it has a greater capacity for data rate, extended range, efficiency, and performance.
Long-range wireless communication offers a few different protocols and technologies. The first one we'll talk about is LPWAN. LPWAN stands for low-power wide-area networking. It's a wireless telecommunication network. There are three protocols associated with LPWAN: LoRaWAN, Sigfox, and Neul.
LoRaWAN stands for long-range wide-area network. It's used with mobile, industrial machine-to-machine, and secure two-way communication for IoT devices, smart cities, and healthcare. Sigfox is good for devices with short battery life that need to transfer low-level data. Neul uses a small part of the TV white space spectrum and delivers high-quality, high-power, high-coverage networks at a low cost. Next, there's Very Small Aperture Terminal, or VSAT. VSAT uses small dish antennas to transfer broadband and narrowband data.
And finally, there's cellular. This communication protocol can send and receive high-quality data over very long distances. However, it's very expensive and consumes a lot of power.
Next we're going to talk about wired communication. There are three main protocols in this category: Ethernet; Multimedia over Coax Alliance, or MoCA; and Power-line Communication, or PLC.
Ethernet is used in LANs. The speed, signaling, media access methods, and cable lengths are defined in the various Ethernet standards published by the IEEE 802.3 committee. There are many Ethernet specifications, but they all use a common naming standard. The word BASE is in the middle. This indicates that the standard uses baseband signaling, not broadband signaling. Baseband updates may improve or diminish battery performance, network signal strength, and roaming capability.
Then we have MoCA. As its name suggests, MoCA uses coaxial cables to provide high-definition videos of a home and other content related to it.
PLC uses electrical wires to transmit power and data from one point to another. PLC is used in different sectors like automation, industrial, and broadband over power lines, or BLP.
One last form of embedded device communication worth mentioning isn't a protocol; it's a card many devices carry inside them called a Subscriber Identity Module card, or SIM card. It encrypts data transmission and stores information about the owner of the device the SIM card is in for identification and authentication. It also stores the International Mobile Subscriber Identity, or IMSI. This is a unique identifier that defines a subscriber in the wireless world, including their country and mobile network.
That's it for this lesson. Today, we discussed the communication of embedded systems. We talked about short-range, medium-range, and long-range protocols. We also covered wired communication and SIM cards. Embedded devices are complex. Learning about their protocols, technologies, and communication models will prepare you to incorporate and safeguard them.

10.8.5 Embedded and Specialized Systems Facts

More and more devices are becoming connected to the internet through embedded technology that allows the device to send and receive information.

This lesson covers the following topics:

- Types of embedded devices
- Security risks

Types of Embedded Devices

The following table describes some of the most common embedded devices:

Device Type	Description
Appliances	Many appliances contain integrated technology that allows internet communication. For example, smart laundry appliances can send notifications when a load is complete or when laundry detergent needs to be refilled. Other common smart home appliances include: Refrigerators Dishwashers Microwaves
Environment controls	Many homes and businesses use environmental control devices that can send real-time information and can be controlled via the internet. These devices can be as basic as controlling a home's HVAC system (such as a Nest thermostat) or as complex as controlling the humidity, temperature, and other environmental factors in a data center.
Building/facility automation	Some facilities use a network of integrated devices that control various aspects, creating what is known as facility automation. Some of the devices that are integrated with facility automation include: Lighting controls Security systems Door locks Sprinkler systems Garage doors Smart meters
Wearable devices	In recent years, companies have started producing wearable devices that can connect to the internet for a variety of purposes. These devices include: Watches Headphones Fitness trackers
Automobiles	Modern cars use integrated technologies and in-vehicle systems that can perform various tasks, such as: Starting the car remotely using a smartphone.

	Warning a driver about nearby cars. Applying the brakes automatically to avoid a collision. Performing parallel parking autonomously.
Industrial equipment	Some industrial equipment also fits into the category of a smart device. Supervisory control and data acquisition (SCADA) devices are special computer systems that gather, analyze, and manage automated factory equipment. For example, a SCADA system could be used to monitor factory pipes and automatically open valves if pressure in the pipe system reaches a specific threshold. SCADA is a subset of Industrial Control Systems (ICS), which refers to all types of industrial automation.
Mainframe computer	A lesser-known category of embedded devices is mainframe computers. A mainframe computer is a large, powerful computer that is capable of processing extremely large amounts of data. Mainframe computers typically run proprietary operating systems. Because these operating systems are rarely updated, they are considered a static environment. In addition, mainframe computers often contain large amounts of sensitive data, making them an attractive target for hackers.
Real-time operating system (RTOS)	A RTOS is an operating system that serves real-time applications without buffer delays. They are generally used in systems that require a response within a strict time constraint. Because RTOS are often used as critical components of an application, a successful attack on the RTOS can harm an entire system, including physical machinery.
System on a chip (SoC)	A SoC is an integrated circuit that includes all components of a typical computer system, including digital, analog, mixed-signal, and radio frequency functions. The Raspberry Pi is a common device that uses a SoC. Because of their relatively low cost, SoCs are often used by hobbyists.
Multi-function display (MFD)	An MFD is a screen surrounded by configurable buttons that can be used to display information in a variety of ways. MFDs are often used on airplanes, helicopters, and ships.
Medical devices	Much of today's medical technology for daily monitoring and maintenance uses embedded systems. Instead of having to visit a physician every day, wearable devices can be used to collect information on heart rate, glucose levels, weight, blood pressure, and other parameters. This information can then be sent to a doctor automatically or used for self-monitoring.
Unmanned aerial vehicles (UAV)	UAVs are used for military campaigns, search and rescue, weather monitoring, and recreation. UAVs use embedded computers for collecting and transmitting data and for receiving commands.
Digital cameras	Most modern digital cameras use embedded systems for processing captured images, storing images, and uploading images to a PC or other storage device.
Media gateways	A media gateway is a translation device that converts media streams for use by different telecommunication technologies.

Wireless keyboards and mice	Wireless keyboards and mice use Bluetooth or other proprietary radio frequency connections.
Displays	In the past, display devices had a single use as a monitor for a computer. Today's monitors and other display devices are increasingly embedded with smart features and have wireless connections.
Wi-Fi-enabled microSD cards	Wi-Fi-enabled MicroSD cards can wirelessly transfer data to and from other devices. Many of them connect directly to the internet.
Multifunction printers (MFPs)	Multifunction printers can connect to wireless networks and the internet for additional functionality.
External storage devices	External storage devices such as USB flash drives, HDDs, and SSDs can connect to traditional computing equipment, as well as to many smart devices.
Arduino	Arduino is an open-source hardware and software company. They design and manufacture single-board microcontrollers as well as kits to build digital devices.
Field Programmable Gate Array (FPGA)	A Field Programmable Gate Array is an integrated circuit manufactured and then later configured by the customer. The configuration happens through a hardware description language (HDL), similar to an application-specific integrated circuit (ASIC).
Voice over IP (VoIP)	Voice over IP is a protocol optimized for the transmission of voice data (telephone calls) through a packet-switched IP network. VoIP routes phone calls through an IP network, including the internet. VoIP solutions can integrate with the public switched telephone network (PSTN) to allow VoIP customers to make and receive external calls.

Security Risks

As with any networked system, there are security risks associated with smart devices. Not only do you have little or no control over the smart technology within static environments, but smart device vendors can be slow to take steps to protect their products against security threats. They tend only to respond after an exploit has occurred instead of proactively updating systems. This is why smart devices are attractive to hackers. However, there are some steps you can take to secure a network from these devices and reduce the damage that a compromised device can cause.

- Some static devices (such as home routers, game consoles, and SCADA devices) require manual firmware updates. With these devices, it is important to keep the firmware updated.
- For devices that cannot be manually updated, the best approach is to minimize the amount of damage a compromised device can cause. This is done by segmenting the network using VLANs or encrypting all network communications.

10.8.6 Practice Questions (Section Quiz)

q_embed_sys_arduino_secp8

Which of the following is an open-source hardware and software company that designs and manufactures single-board microcontrollers as well as kits to build digital devices?

Answers:

Raspberry Pi

Microsoft

Amazon

***Arduino**

Explanation:

Arduino is an open-source hardware and software company. They design and manufacture single-board microcontrollers as well as kits to build digital devices.

Raspberry Pi is a common device that uses a system on a chip (SoC).

Neither Microsoft nor Amazon are an open-source hardware and software company that designs and manufactures single-board microcontrollers as well as kits to build digital devices.

q_embed_sys_facility_secp8

You manage information systems for a large co-location data center.

Networked environmental controls are used to manage the temperature within the data center. These controls use embedded smart technology that allows them to be managed over an internet connection using a mobile device app.

You are concerned about the security of these devices.

What can you do to increase their security posture? (Select two.)

Answers:

***Verify that your network's existing security infrastructure is working properly.**

Install anti-malware software on each device.

Enroll each device in a mobile device management (MDM) system.

Rely on the device manufacturer to maintain device security with automated firmware updates.

***Install the latest firmware updates from the device manufacturer.**

Explanation:

Since you generally have little or no control over the embedded technology within smart environmental control devices, they are referred to as static environments. As a result, there is typically very little you can do to increase the security posture for these types of devices. For environmental controls, you may be able to perform the following, depending upon the device manufacturer:

Install the latest firmware updates from the device manufacturer.

Verify that your network's existing security infrastructure is working properly.

Because these devices operate in a static environment, you typically can't install third-party software on them, including anti-malware scanners or mobile device management (MDM) agents.

Relying on the device manufacturer for security updates is problematic because manufacturers can be slow to take steps to protect their products against security threats.

Manufacturers tend only to respond after an exploit has occurred instead of proactively defending their systems.

q_embed_sys_fpga_secp8

Which of the following embedded devices is an integrated circuit that is manufactured and then later configured by the customer through a hardware description language (HDL)?

Answers:

System on a chip (SoC)

Multi-function display (MFD)

***Field-programmable gate array (FPGA)**

Real-time operating system (RTOS)

Explanation:

Field-programmable gate array (FPGA) is the correct answer. An FPGA is an integrated circuit that is manufactured and then later configured by the customer through a hardware description language (HDL).

A SoC is an integrated circuit that includes all components of a typical computer system, including digital, analog, mixed-signal, and radio frequency functions. However, it is not configured by the customer after manufacturing.

An MFD is a screen surrounded by configurable buttons that can be used to display information in a variety of ways. It is not an integrated circuit that is configured by the customer after manufacturing.

An RTOS is an operating system that serves real-time applications without buffer delays. It is not an integrated circuit that is configured by the customer after manufacturing.

q_embed_sys_manu_secp8

You manage the information systems for a large manufacturing firm.

Supervisory control and data acquisition (SCADA) devices are used on the manufacturing floor to manage your organization's automated factory equipment. The SCADA devices use embedded smart technology, allowing them to be managed using a mobile device app over an internet connection.

You are concerned about the security of these devices.

What can you do to increase their security posture? (Select two.)

Answers:

***Install the latest firmware updates from the device manufacturer.**

***Verify that your network's existing security infrastructure is working properly.**

Install anti-malware software on each device.

Enroll each device in a mobile device management system.

Install a network monitoring agent on each device.

Explanation:

Since you generally have little or no control over the smart technology embedded within SCADA devices, they are referred to as static environments. As a result, there is typically very little you can do to increase the security posture for these types of devices. For SCADA devices, you may be able to perform the following, depending on the device manufacturer:

Install the latest firmware updates from the device manufacturer.

Verify that your network's existing security infrastructure is working properly.

Because these devices operate in a static environment, you typically can't install third-party software on them, including anti-malware scanners, monitoring agents, or mobile device management agents.

q_embed_sys_rtos_01_secp8

Which of the following serves real-time applications without buffer delays?

Answers:

SCADA

SoC

FPGA

***RTOS**

Explanation:

A real-time operating system (RTOS) is an operating system that serves real-time applications without buffer delays. They are generally used in systems that require a response within a strict time constraint.

Supervisory control and data acquisition (SCADA) devices are special computer systems that gather, analyze, and manage automated factory equipment.

A system on a chip (SoC) is an integrated circuit that includes all components of a typical computer system, including digital, analog, mixed-signal, and radio frequency functions.

A field-programmable gate array (FPGA) is an integrated circuit manufactured and then later configured by the customer.

q_embed_sys_rtos_02_secp8

At a manufacturing facility, the security team for an IoT-based system implemented various efforts to monitor and control multiple processes using embedded systems.

The security team employed real-time operating systems (RTOS) to ensure precise and timely data processing. The security team recognized the importance of safeguarding these IoT devices and embedded systems against potential cyber threats.

The team plans to implement security BEST practices and protocols.

How would the security team explain why they want to implement security best practices and protocols in the manufacturing facility's IoT devices and embedded systems?

Answers:

***To reduce the risk of unauthorized access and data breaches in the RTOS and embedded systems.**

To ensure the precise monitoring and control of manufacturing processes.

To develop new security protocols tailored specifically for IoT devices.

To improve the manufacturing facility's overall efficiency and productivity.

Explanation:

The team wants to implement security best practices and protocols to reduce the risk of unauthorized access and data breaches in the real-time operating systems, Internet of Things (IoT) devices, and embedded systems used in the manufacturing facility.

Ensuring the precise monitoring and control of manufacturing processes is not the primary focus of security best practices and protocols. Instead, security best practices and protocols aim to enhance security rather than precise monitoring and control.

Developing new security protocols is irrelevant to implementing established best practice security protocols applicable to various devices, including IoT.

Efficiency and productivity do not relate to implementing security best practices and protocols. Instead, they are essential in business operations.

q_embed_sys_scada_secp8

Which of the following devices are special computer systems that gather, analyze, and manage automated factory equipment?

Answers:

***SCADA**

SoC

MFD

UAV

Explanation:

Supervisory control and data acquisition (SCADA) devices are special computer systems that gather, analyze, and manage automated factory equipment.

A system on a chip (SoC) is an integrated circuit that includes all components of a typical computer system, including digital, analog, mixed-signal, and radio frequency functions.

A multi-function display (MFD) is a screen surrounded by configurable buttons that can be used to display information in a variety of ways.

Unmanned aerial vehicles (UAVs) are used for military campaigns, search and rescue, weather monitoring, and recreation.

q_embed_sys_soc_secp8

Which of the following do Raspberry Pi systems make use of?

Answers:

SCADA

***SoC**

FPGA

RTOS

Explanation:

A system on a chip (SoC) is an integrated circuit that includes all components of a typical computer system, including digital, analog, mixed-signal, and radio frequency functions. Raspberry Pi is a common device that uses an SoC. Because of their relatively low cost, SoCs are often used by hobbyists.

A real-time operating system (RTOS) is an operating system that serves real-time applications without buffer delays. They are generally used in systems that require a response within a strict time constraint.

Supervisory control and data acquisition (SCADA) devices are special computer systems that gather, analyze, and manage automated factory equipment.

A field-programmable gate array (FPGA) is an integrated circuit configured by the customer.

q_embed_sys_uav_secp8

Which of the following embedded devices is primarily used for tasks such as military campaigns, search and rescue, weather monitoring, and recreation?

Answers:

Appliances

Environment controls

***Unmanned aerial vehicles (UAV)**

Multi-function display (MFD)

Explanation:

Unmanned aerial vehicles (UAV) is the correct answer. UAVs are used for a variety of tasks including military campaigns, search and rescue, weather monitoring, and recreation. They use embedded computers for collecting and transmitting data and for receiving commands.

While many modern appliances do contain integrated technology that allows for internet communication, they are not primarily used for tasks such as military campaigns, search and rescue, weather monitoring, or recreation.

Environment controls are devices that send real-time information and can be controlled via the internet. They are used for controlling a home's HVAC system or controlling the humidity, temperature, and other environmental factors in a data center, not for tasks such as military campaigns, search and rescue, weather monitoring, or recreation.

A multi-function display (MFD is a screen surrounded by configurable buttons that can be used to display information in a variety of ways. They are often used on airplanes, helicopters, and ships, but they are not used for tasks such as military campaigns, search and rescue, weather monitoring, or recreation.

q_embed_sys_vlan_secp8

As a network security analyst, you have been tasked with improving the security of a network that includes a variety of embedded devices, including appliances, wearable devices, and industrial equipment.

The network has been experiencing frequent security breaches.

Which of the following would be the MOST effective strategy to improve network security?

Answers:

Implementing a firewall for each individual device.

***Using VLANs or encrypting all network communications.**

Regularly updating the firmware of all devices.

Disabling all unnecessary services on the devices.

Explanation:

Using VLANs or encrypting all network communications is the correct answer. Using VLANs can help segment the network and isolate traffic, reducing the potential impact of a security breach. Encrypting all network communications can help protect data in transit and prevent unauthorized access.

While firewalls can provide an additional layer of security, implementing a firewall for each individual device can be resource-intensive and may not be feasible or effective in a network with a variety of embedded devices.

While regularly updating the firmware of all devices can help address known vulnerabilities, it may not be sufficient to protect against all potential security breaches, especially if the network communications are not secure.

While disabling unnecessary services can reduce potential attack vectors, it may not be sufficient to protect against all potential security breaches, especially if the network communications are not secure.

q_embed_sys_voip_secp8

Which of the following lets you make phone calls over a packet-switched network?

Answers:

***VoIP**

FPGA

RTOS

SCADA

Explanation:

Voice over IP (VoIP) is a protocol optimized for the transmission of voice data (telephone calls) through a packet-switched IP network. VoIP routes phone calls through an IP network, including the internet. VoIP solutions can integrate with a public-switched telephone network (PSTN) to allow VoIP customers to make and receive external calls.

A field-programmable gate array (FPGA) is an integrated circuit configured by the customer.

A real-time operating system (RTOS) is an operating system that serves real-time applications without buffer delays. They are generally used in systems that require a response within a strict time constraint.

Supervisory control and data acquisition (SCADA) devices are special computer systems that gather, analyze, and manage automated factory equipment.

10.9 Email

As you study this section, answer the following questions:

How does spam filtering help end users?

In what format are emails sent?

Why is it important to add multiple layers of security?

Why would you encrypt email coming only from outside your network?

What is S/MIME?

What is the difference between POP3 and IMAP?

In this section, you will learn to:

Protect a client from spam.

Secure an email server.

Configure email filters.

Secure accounts on an iPad.

Secure email on an iPad.

The key terms for this section include:

Term	Definition
Spam	Unwanted and unsolicited email usually sent to many recipients.
SMTP relay	An email server that accepts mail and forwards it to other mail servers.
Phishing email	A fraudulent email claiming to be from a trusted organization. The email typically asks a user to verify personal information or send money.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.4 Given a scenario, analyze indicators of malicious activity. Malware attacks Virus Application attacks 3.2 Given a scenario, apply security principles to secure enterprise infrastructure. Secure communication/access Tunneling Transport Layer Security (TLS) 4.1 Given a scenario, apply common security techniques to computing resources. Application security Secure cookies 4.5 Given a scenario, modify enterprise capabilities to enhance security. Email security Domain-based Message Authentication Reporting and Conformance (DMARC)

	DomainKeys Identified Mail (DKIM) Sender Policy Framework (SPF) Gateway DLP 5.6 Given a scenario, implement security awareness practices. Phishing
TestOut Security Pro	3.2 Implement Application Defenses 3.2.1 Implement an application allow list 3.2.4 Configure email filters and settings 3.2.5 Configure browser settings

10.9.1 Email Security (Lesson Video)

Transcript:

Email security is a big issue for IT professionals. Spam, viruses, malware, social engineering all use email as the vehicle to carry out an attack. In addition, a lot of sensitive information is sent via email.

In this lesson, we're going to talk about the steps you should take to properly secure email communications and reduce the risk of email exploits. Let's start by looking at a comprehensive email security solution called an email security gateway.
An email security gateway is a security solution that monitors emails that are sent to or originate from an organization.
An email security gateway can be software-, hardware-, or cloud-based. There are even some virtualized email security gateways that function on a hypervisor.
Hardware-based gateways are typically installed in a server room and are configured to have all email messages routed through the device. Software- or cloud-based gateways function in the same way by routing email messages through the service.
Depending on the solution, an email security gateway can offer things like spam protection, malware and virus scanning, email encryption, and even data loss prevention. Let's take a look at some of the features that most email security gateways offer.
Spam filtering is offered by a lot of gateways. As its name suggests, spam filtering is to filter out certain types of email. The filter will try to filter out unwanted or unsolicited emails and prevent them from arriving to the end users.
Spam filters use various methods in order to identify spam. Some services even use lists that are continually updated with known spammers and automatically block anything from those emails or domains.
One thing to know about spam filters is that they are far from perfectâ€"they are not a silver bullet. In fact, fine-tuning a spam filter is a never-ending process. Spammers are constantly finding ways to trick spam filters in order to get emails through and sometimes legitimate emails will be flagged and blocked by the filtering device. However, the benefits of using a spam filter far outweigh the time it takes to configure one.
Another feature provided by a lot of email security gateways is that of data loss prevention, or DLP.
Gateways that employ DLP scan all outgoing emails for sensitive information. Both the message body and attachments are scanned and if sensitive information is found, the email will be blocked. If desired, a notification can also be sent to the sender or system administrator.

For example, let's say an employeeâ€""either accidently or purposelyâ€""sends an email that contains a customer's credit card information to a personal email address. When the email is sent, it is filtered through the email gateway where it is scanned by the DLP feature. Because the email contains sensitive information, the gateway blocks the email from being sent outside the network. The gateway then notifies the employee that their email was blocked and that the system administrator has been notified.

Just like a spam filter, a DLP solution isn't prefect. Its success depends entirely on how advanced the scanning algorithm is and how well the gateway was configured. Because of this, it's important you understand how to properly configure DLP on a gateway.

The next email security gateway feature we'll look at is encryption.

Remember, email sent over the internet isn't very secure. Emails can be intercepted by someone with the right know how. And because email messages aren't encrypted by default, they can be easily read. To protect against this, you can use email encryption as a standalone or as part of an email security gateway.

As its name suggests, email encryption encrypts the entire contents of an email and, in some cases, will digitally sign the email with a certificate. This certificate is similar to SSL certificates in that they provide a form of identity verification.

Email encryption can be configured in a few different ways.

One way is to encrypt all email communications, regardless of destination. Doing this does provide the most protection; however, encrypting and decrypting emails requires a lot of resources. And if hundreds or even thousands of emails are being sent a day, this might not be feasible.

Another option is to only encrypt emails that are being sent outside the internal network. With this method, that funny cat video you email to Rick in accounting won't be encrypted, but the contract document you send to your client will be.

Now, even if you only encrypt outgoing emails, this encryption and decryption can still become a resource bottleneck. Luckily, some security gateways offer selective encryption. With this option, outgoing emails are scanned in a similar way that a DLP solution scans emails. If sensitive information is found, then the email is encrypted before its sent. If no sensitive information is found, then the email is sent unencrypted.

Now, this encryption and digital signing can be done using several different encryption protocols, such as PGP, GPG, or TLS. However, the most common and widely accepted protocol for email encryption is the S/MIME protocol, which stands for Secure/Multipurpose Internet Mail Extensions. The important thing to understand about S/MIME is that it requires the use of a public key certificate in order to encrypt and decrypt email messages. This certificate can either be self-signed or purchased from a public CA, but it is required.

Typically, two certificates are used: one for encrypting the email and another for digitally signing the email. Digitally signing the email ensures that only the intended recipient is able to decrypt the email message and also verifies that the email originated from a trusted source.

In addition to using an email security gateway, you can also further secure email communications by ensuring you are using the latest email protocols.

Whether you are using POP or IMAP, make sure to use the latest version of the protocol. In addition, both of these protocols support the use of SSL/TLS in order to create a secure tunnel when connecting to an email server. One way to do this is to use a Microsoft Exchange server and enable secure POP or secure IMAP communication.

Proper email security is an extremely important aspect of network security. Emails can be a vehicle for countless attacks and exploits. As such, you need to make sure you take the appropriate steps in order to properly secure your organizations email communications and prevent email-driven attacks.

10.9.2 Email Security Facts

This lesson covers the following topics:

- Email threats
- Email security

Email Threats

To secure email, you must be aware of the following email attacks.

Attack	Description
Virus	A virus is malware that often uses email as its distribution mechanism. Users receive the virus as an attachment and then activate the virus by clicking on that attachment. To mitigate viruses, you should install antivirus software on every system and install antivirus software on the email server to scan attachments. A best practice is to detect viruses and messages on the email server before they get to the client and send warnings to the recipient about the malicious email.
Spam	Spam is unwanted and unsolicited email sent to many recipients. Spam consists of the following attributes: Can be as benign as emails trying to sell products Can be malicious and contain phishing content, drive-by downloads, or malware Can contain malware as attachments Wastes bandwidth and could fill the inbox, resulting in a denial-of-service condition To control spam: Enable spam filters on the client and email servers. Filter junk email by identifying safe senders (whitelists), blocked senders (blacklists), countries to block email from, and languages to block. Enable antivirus scanning for attachments on the client and email servers. In the email client, disable preview screens. An email can have links for active items that can report back to the spammer. Do not click on an unsubscribe link at the bottom of an unsolicited email. Doing this verifies to the spammer that the email address is a current and active email address. Only unsubscribe from trusted organizations. Install server-level anti-spam software on the email server. Do not post your full email address anywhere on the web. Spammers use software to scan websites to find email addresses and then add them to their email lists for spamming.
Open SMTP relay	An SMTP relay is an email server that accepts mail and forwards it to other mail servers. An open SMTP relay allows anyone to forward mail. If your mail server is an open SMTP relay, it can be used by spammers to send mail. Spammers use your relay to obscure the actual source of the email. A repudiation attack is an attack on open relays in which the attacker accesses your email server and sends spoofed emails to others, making them appear as if they came from you.

	If spammers use your relay for sending mail, your server will soon be placed on a blacklist. Other mail servers then stop receiving any mail (even legitimate mail) sent from your servers. As a best practice: Configure your mail server to accept mail only from authenticated users or specific email servers that you authorize. Require TLS encryption to connect to the server. Implement restrictions for accessing the server and relaying email for your environment if feasible.
Phishing	A phishing email is an email pretending to be from a trusted organization that asks to verify personal information or send money. In a phishing attack: A fraudulent message (that appears to be legitimate) is sent to a target. The message requests that the target visit a fraudulent website (which also appears to be legitimate). Graphics, links, and web pages look almost identical to the legitimate requests and websites the attacker tries to represent. The fraudulent website requests that the victim provide sensitive information, such as the account number and password. To protect against phishing: Check the email header information to see more info about the sender and the links that are in the email. Only open emails if you recognize the sender. Check the actual link destination within emails to verify that they go to the correct URL and not a spoofed one. Do not click on links in emails. Instead, type the real URL into the browser. You could also look up the website in a search engine. Verify that HTTPS is used when going to e-commerce sites. HTTPS requires a certificate that matches the server name in the URL that is verified by a trusted CA. You can also look for the lock icon to verify that HTTPS is used. Implement phishing protections within your browser.

In addition, there are several protocols that help identify and mitigate phishing and spam emails by authenticating sender identities and checking message integrity, including protocols such as SPF (Sender Policy Framework), DKIM (DomainKeys Identified Mail), and DMARC (Domain-based Message Authentication, Reporting & Conformance). These protocols establish trust in email communications, reducing the likelihood of successful phishing and spam attacks.

Below are a few characteristics of the protocols mentioned above:

Protocol	Description
Sender Policy Framework (SPF)	This is an email authentication method that helps detect and prevent sender address forgery commonly used in phishing and spam emails. SPF works by verifying the sender's IP address against a list of authorized sending IP addresses published in the DNS TXT records of the email sender's domain. When an email is received, the receiving mail server checks the SPF record of the sender's domain to verify the email originated from one of the pre-authorized systems.
DomainKeys Identified Mail (DKIM)	This protocol leverages encryption features to enable email verification by allowing the sender to sign emails using a digital signature. The receiving email server uses a DKIM record in the sender's DNS record to verify the signature and the email's integrity.
Domain-based Message Authentication, Reporting and Conformance (DMARC)	DMARC uses the results of SPF and DKIM checks to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message. DMARC also provides reporting capabilities, giving the owner of a domain visibility into which systems are sending emails on their behalf, including unauthorized activity.

Email Security

Email is cleartext by default. To secure email, use either Secure/Multipurpose Internet Mail Extensions (S/MIME) or Pretty Good Privacy (PGP).

- Both solutions use certificates to provide authentication, message integrity, non-repudiation (through digital signatures), and privacy (encryption).
- Certificates are bound (associated) with an email address.
- To prove who has sent an email, a digital signature is added using the sender's private key. Only the sender who has the private key could have sent the message.
- To encrypt email, the message is encrypted using the recipient's public key. Only the recipient who has the private key can decrypt the message. Before you send an encrypted email to someone, you must first obtain their public key, which is normally done by having them send you a signed email.
- S/MIME uses certificates issued by either public or in-house CAs using the X.509 system.
- PGP uses two methods for validating certificates:
  - With a web of trust, individual users decide which certificates they trust. Users can then trust other designated users to introduce or recommend additional trusted users.
  - With trust signatures, digital signatures from certain certificates are trusted as being able to sign other keys. Trust signatures create a hierarchy similar to that of Certificate Authorities.
- Both S/MIME and PGP are used primarily for email encryption, although PGP can also be used for encryption of phone calls and whole disk encryption.

10.9.3 Protecting a Client from Spam (Demo Video)

Transcript:

In this demo, we're going to talk about protecting a client from spam. We're going to look at spam settings in two email services. One is Gmail, and we're going to access it through a web browser. The other is the Outlook web mail client.

Let's start with Gmail. I already have my browser open, and I've logged into Gmail. It has a few functions that are set up automatically to help you organize and sort out types of email, especially spam.
When I come down here and select this email, I get some options, including Report Spam. If I select that, it'll be moved to my Spam folder, and all emails coming from this address will be marked as spam. I'll undo that for this email.
Another thing I can do is right-click and look at some more options. A better choice for this email might be to label it Promotions rather than Spam. Now let's click on the Promotions tab and see what's in there. I see several emails, many already sorted for me. If I right-click again, I can see, under Label As, that it's labeled Promotions.
Let's look at the contents of our Spam Folder. If I click on it, we can see several emails in there. If you find some emails in here that aren't spam, you can select them and then click Not Spam. All emails in this folder are deleted 30 days after they arrive.
Now let's look at the settings. Here, you'll find Filters and Blocked Addresses. Down here, you'll find the email addresses you've previously blocked. These emails are marked as spam. If, for some reason you need to change that, this is where you do it.
Now let's look at another web-based email client, Outlook. I'm already in Outlook, and here's my inbox. I have one email down here. Let's select it. I have a tab up here called Junk. When I click on it, I get a dropdown, and I have a few choices: Junk, Phishing, and Block. Let's click each of these for more information.
First, I'll click on Junk. This will add this email to the list of Spam mail senders. I can change my mind and click Undo.
Next, click on Phishing. When we do that, this email is reported as a Phishing email to Microsoft so they can better detect these on their end. This isn't a Phishing email, so I'll click the Don't Report button.
The third option is Block. This won't report the email, but maybe it's just one that I don't care to receive any longer, and unsubscribing doesn't help. Once again, I'll cancel and not really block the email.
Let's take a look at the Junk Email folder. I have two emails in here that aren't junk, so I'll tell Outlook that, and they'll go back to my inbox. I'll do that for both emails. Now, if I look at my inbox, both emails are there.
Let's look at our settings in Outlook. I'll click on the Junk Email option here. Let's look at our options. We can block senders or entire domains from sending you email. I click on Add, and I can put in an email address or a domain that I want to block. Or maybe a sender is getting labeled as spam, but it isn't spam. If that's the case, I can add those emails and domains here, under the Safe senders and domains list. The last one here is Safe mailing lists. For example, I'm a member of several mail lists related to tech, and many spam filters mark them as spam. I can enter them here to make sure that doesn't happen.
At the bottom of the page, we have a couple of filters. The first one is to only trust emails from my Safe senders and domains list. This would be pretty restrictive and take a lot of updating. But if you only want to use this email to communicate with coworkers or family members, this might be a great thing, especially for children or the elderly. The next one will block attachments from anyone not in your Safe senders and domains list. This isn't as restrictive, and it's probably a good way to prevent malware from coming to your mailbox.
Be aware that these are just client settings, and on the server side of things, you probably have even more settings. In addition, ISPs and mail hosts are filtering emails before they even arrive to your client. In general, processes for catching spam have come a long way, but you still have to do some things manually.
That's it for this demo. In this demo, we configured spam filtering in Gmail and Outlook.

10.9.4 Securing an Email Server (Demo Video)

Transcript:

In this demonstration, we'll discuss how to prevent spam from being relayed off your email servers. To do this, we've installed an SMTP email service on this Windows Server 2022 system. Let's go to Tools.

We're going to go to the IIS 6.0 Manager. Expand that. We managed this service using the IIS Manager 6.0. Most email servers currently available will have similar SMTP capabilities and provide the same SMTP options.
Firstly, we can right-click on our SMTP server. Go to Properties. From here, we can lock down this email server. We're going to go to the Access tab. On the Access tab, you can require authentication to access this server. The default is Anonymous access, meaning anybody can connect without authenticating. You should disable this option and require at least Basic authentication.
If you have Anonymous authentication enabled and allow open relay, spammers will quickly find this system and start bouncing spam off your server to cover their tracks. If this happens, you're the one who gets in trouble, and your ISP may block your email server.
You can also use Integrated Windows Authentication, which would require you to use the domain credentials to authenticate. Basic authentication requires users just to enter a password but be aware that basic authentication is sent clear text by default, which would expose the password.
Alternatively, you can combine it with TLS encryption, the next generation of SSL, to secure authentication credentials as they're transmitted on the network. You can also require a secure connection to connect to this SMTP server in the first place.
This option requires an SSL or TLS certificate for this server to secure the connection. You can also use Connection control to configure who's allowed to connect to this SMTP server and who is blocked from connecting. This can be done using your IP addresses. You can use a range of IPs.
You can also do this using domain names as well. This requires reverse DNS lookups to be enabled. Using this information, you can restrict who is allowed access to the server. You can also implement Relay restrictions, which specify who is allowed to relay email through the SMTP server. You can allow everyone except those specified on the list or block everyone except those on the list. As before, you can also specify an IP or IP range or a domain name.
That's it for this demonstration. In this demonstration, we reviewed a few security configurations you can implement to prevent email from being relayed off of your SMTP server.

10.9.5 Configure Email Filters (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You helped your boss remove a lot of junk email, and now he would like you only to allow emails and attachments from senders on his safe sender list.

In this lab, your task is to:

Configure email filtering as follows:

- Only allow emails from the safe senders list.
- Report junk email messages to your email provider.
- Only allow attachments from the safe senders list.

Explanation

Complete this lab as follows:

Access the WebEmail filtering and reporting options.

- In the upper right corner of the WebEmail interface, select **Options** > **More Options** .
- Under *Preventing junk email* , select **Filters and reporting** .

Configure the Filters and reporting options.

Under *Choose a junk email filter* , select **Exclusive** .

Under *Report junk messages* , select **Report junk** .

Under *Block content from unknown senders* , select **Block attachments, pictures, and links for anyone not in my safe senders list** .

Select **Save** .

10.9.6 Securing Accounts on an iPad (Demo Video)

Transcript:

In this demonstration, we'll show you techniques to secure accounts on an iPad, specifically email and web browsing.

The web browser and email client on a mobile device, as with any computer, represent one of the most serious and most easily attacked vectors into the device.
Just as you need to secure the web browser and email client on a Windows workstation, you need to secure them on mobile devices as well. Let's take a look at some things you can do.
We're currently using an iPad to do this demonstration. For email, one of the key things we can do is use SSL to communicate with the mail server. This includes POP or IMAP servers, as well as the SMTP server. Let's look at how we do that.
Let's go into Settings. We'll scroll up to Passwords & Accounts Then we'll go into this Gmail account. To do that, we tap on the email address to get into the Account settings.
At the bottom, there's an Advanced selection. Tap on Advanced. You can see that we are using SSL to encrypt communications between the mail client on this mobile device and the mail server.
For this to work, the mail server for POP, IMAP, and SMTP, must be configured to support SSL. If it isn't, then turning this on won't accomplish anything.
Remember that POP3, IMAP, and SMTP transmit clear text by default. So, using SSL greatly increases the security of your email communications.
If you're using a mobile device to send email messages to someone through your mail server and you're not using SSL, then any sensitive proprietary information in that email is being transferred in clear text. It could be sniffed and read by almost anyone.
Using SSL sets up an SSL tunnel between the email client and the mail server. The SSL tunnel secures message transmission through that tunnel. It is already enabled here.
In addition to securing your email account, you also need to secure the web browser on a mobile device. Because we're using an iPad, Safari is the browser. Let's get out of the account and go to Safari Settings.
We can do several things to increase the overall security of the web browser. First, let's look at autofill. Notice that Use Contact Info is on.
To increase security, we'll turn that off. In addition, Credit Cards is also on. We'll also turn that off. This option automatically fills out credit card information. We don't want to do that; so let's keep that off.
Now we'll have to manually fill in contact and credit card information in various web forms. Autofill is a security challenge on a workstation in an office. It's a bigger problem on a mobile device.
Let's look at one more thing. We'll go back up and tap Passwords & Accounts, on the right we might want to turn off AutoFill Passwords. That way if we lose this device, someone can't access sites by having the passwords automatically populated.
We're done with this. Let's go back and go to the main Safari settings. Now we want to look at cookies. Scroll down. As you can see here under Privacy and Security, we have Cookies, and the Block All Cookies option. That's currently, that's turned off. That means that it will not block cookies. Let's turn that on.
When we turn it on, we are asked, "Hey, are you sure you want to block all cookies?" Because if we do, some websites are not going to work and the existing cookies will be removed. Let's tap Block All Cookies, and say goodbye to them.
Let's go back. Now we need to enable Fraudulent Website Warning. This is right below our Block All Cookies. This will warn us if we're visiting a site the browser thinks is a potentially fraudulent website. Right now, you can see it's turned off. Let's turn that on.

If we scroll down and tap Advanced, we can see that JavaScript is currently on. This is one of those issues where you have to balance functionality and security, just like with the cookies. Having JavaScript enabled makes the browser on this device more functional, but it also opens up security issues. The general advice is to disable JavaScript.
There will be sites that don't function properly, however, because it's commonly used in a lot of websites, but it does increase the security of the device. We can turn it off if we want to, so let's select to turn that off.
The last thing we're going to do to secure Safari is to make sure that we're blocking pop-ups. When we look here, we can see Block pop-ups is not currently on.
Let's go ahead and turn that on. That'll stop many of those annoying pop-up windows that are so common on the internet. It will help get rid of any of the annoying ads. Also, we want to prevent drive by downloads from occurring. At this point, the Safari web browser is much more secure than it was.
In this demo, we talked about things you can do to secure email and the web browser on a mobile device. In this case, an iPad. We configured the POP3 or IMAP and SMTP protocols to secure communications between the web client and the web server using SSL.
Then, we looked at what you can do to secure the Safari web browser on an iPad. We disabled autofill, we restricted cookies, we turned fraud warning on, and we turned JavaScript off. Then, we finished by turning on the pop-up blocker.

10.9.7 Secure Email on iPad (Simulation)

Scenario

You work as the IT security administrator for a small corporate network. The receptionist, Maggie Brown, uses an iPad to manage employee schedules and messages. You need to help her secure her email and browser on her iPad.

In this lab, your task is to complete the following:

Configure Maggie's email account to use SSL for incoming mail.

Secure the internet browser as follows:

Turn off AutoFill

Turn on Block Pop-ups

Block all cookies

Turn on Fraudulent Website Warning

Turn off JavaScript

Explanation

Complete this lab as follows:

Configure email for SSL.

Select **Settings** .

Scroll down and select **Mail** .

From the right pane, select **Accounts** .

Select **Maggie Brown** .

Select **Account mbrown@gmail.com** .

Select **Advanced** .

Under *Incoming Settings* , set *Use SSL* to **ON** .

From the top, select **Account** to return to the Account menu.

Select **Done** .

Turn off AutoFill.

From the Settings menu, scroll down and select **Safari** .

From the right pane, select **AutoFill** .

Set Use Contact Info to **OFF** .

Set Names and Passwords to **OFF** .

From the top, select **Safari** to return to the Safari menu

Block all pop-ups and cookies.

From the right pane, set Block Pop-ups to **ON** .

Scroll down and set Block All Cookies to **On** .

Turn on the Fraudulent Website Warning and turn off JavaScript.

From the right pane, set Fraudulent Website Warning to **ON** .

Scroll down and select **Advanced** .

Set JavaScript to **OFF** .

10.9.8 Practice Questions (Section Quiz)

q_email_sec_blacklist_secp8

You have been receiving a lot of phishing emails sent from the domain kenyan.msn.pl. Links within these emails open new browser windows at youneedit.com.pl.

You want to make sure that these emails never reach your inbox, but you also want to make sure that emails from other senders are not affected.

What should you do?

Answers:

***Add kenyan.msn.pl to the email blacklist.**

Add pl to the email blacklist.

Add youneedit.com.pl to the email blacklist.

Add msn.pl to the email blacklist.

Explanation:

Add **kenyan.msn.pl** to the email blacklist.

Adding **msn.pl** or **pl** to the blacklist filters out all emails from kenyan.msn.pl, but this also filters out other emails from the msn.pl or pl domains.

Adding **youneedit.com.pl** to the email blacklist would prevent emails from that domain, but it would not prevent emails from kenyan.msn.pl, nor would it prevent links in the emails from opening windows to youneedit.com.pl.

q_email_sec_dkim_secp8

A cyber technician is enhancing application security capabilities for corporate email accounts following a breach.

Which of the following leverages encryption features to enable email verification by allowing the sender to sign emails using a digital signature?

Answers:

***DomainKeys Identified Mail (DKIM)**

Domain-based Message Authentication, Reporting and Conformance

Sender policy framework (SPF)

Endpoint detection and response (EDR)

Explanation:

DomainKeys Identified Mail (DKIM) leverages encryption features to enable email verification by allowing the sender to sign emails using a digital signature.

Domain-based Message Authentication, Reporting and Conformance (DMARC) checks to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message.

Sender policy framework (SPF) is an email authentication method that helps detect and prevent sender address forgery, commonly used in phishing and spam emails.

An endpoint detection and response (EDR) product's aim is not to prevent initial execution, but to provide real-time and historical visibility into the compromise, contain the malware within a single host, and facilitate remediation of the host to its original state.

q_email_sec_dmarc_01_secp8

You are the IT manager of a large corporation and have been receiving numerous complaints about phishing and spam emails.

You decide to implement a protocol that not only verifies the sender's IP address and checks the email's integrity but also defines rules for handling messages and provides reporting capabilities.

Which protocol should you implement?

Answers:

Sender Policy Framework (SPF)

DomainKeys Identified Mail (DKIM)

***Domain-based Message Authentication, Reporting and Conformance (DMARC)**

Virtual local area network (VLAN)

Explanation:

Domain-based Message Authentication, Reporting and Conformance (DMARC) is the correct answer. DMARC uses the results of SPF and DKIM checks to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message. DMARC also provides reporting capabilities, giving the owner of a domain visibility into which systems are sending emails on their behalf, including unauthorized activity. Therefore, this answer is correct.

While SPF does help in verifying the sender's IP address against a list of authorized sending IP addresses, it does not provide the capability to define rules for handling messages or provide reporting capabilities. Therefore, this answer is incorrect.

DKIM allows the sender to sign emails using a digital signature, which the receiving email server can verify. However, like SPF, it does not provide the capability to define rules for handling messages or provide reporting capabilities. Therefore, this answer is incorrect.

A VLAN is a network topology configuration for creating distinct broadcast domains. It is not a protocol for email security or spam prevention. Therefore, this answer is incorrect.

q_email_sec_dmarc_02_secp8

A technician is modifying controls to increase securities on messaging services.

Which of the following options check to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message?

Answers:

***Domain-based Message Authentication, Reporting and Conformance (DMARC)**

Sender policy framework (SPF)

Endpoint detection and response (EDR)

DomainKeys Identified Mail (DKIM)

Explanation:

Domain-based Message Authentication, Reporting and Conformance (DMARC) checks to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message.

Sender policy framework (SPF) is an email authentication method that helps detect and prevent sender address forgery, commonly used in phishing and spam emails.

An endpoint detection and response (EDR) product's aim is not to prevent initial execution, but to provide real-time and historical visibility into the compromise, contain the malware within a single host, and facilitate remediation of the host to its original state.

DomainKeys Identified Mail (DKIM) leverages encryption features to enable email verification by allowing the sender to sign emails using a digital signature.

q_email_sec_email_secp8

You install a new Linux distribution on a server in your network. The distribution includes a Simple Mail Transfer Protocol (SMTP) daemon that is enabled by default when the system boots. The SMTP daemon does not require authentication to send email messages.

Which type of email attack is this server susceptible to?

Answers:

***Open SMTP relay**

Phishing

Sniffing

Viruses

Explanation:

An SMTP relay is an email server that accepts mail and forwards it to other mail servers, and an open SMTP relay allows anyone to forward mail if they choose. If your mail server is an open SMTP relay, spammers can also take advantage of it to obscure the actual source of the email. If spammers use your relay for sending mail, your server may soon be placed on a blacklist. Other mail servers will then stop receiving any mail (even legitimate mail) sent from your servers. As a best practice:

Configure your mail server to accept mail only from authenticated users or specific email servers that you authorize.

Require TLS encryption to connect to the server.

A phishing scam uses an email pretending to be from a trusted organization that asks you to verify personal information or send money.

Sniffing occurs when a user captures packets from a network and inspects their contents.

Viruses are types of malware that spread by infecting legitimate files on a computer system and are sometimes sent as email attachments.

q_email_sec_pgp_secp8

You are the IT security manager for a global company that frequently exchanges sensitive information via email.

The company has been using Secure/Multipurpose Internet Mail Extensions (S/MIME) for email security, but due to recent cyber threats, you are considering implementing an additional layer of security.

Which of the following options would provide the MOST robust solution for securing your company's email communications?

Answers:

Implementing DomainKeys Identified Mail (DKIM)

Implementing Sender Policy Framework (SPF)

***Implementing Pretty Good Privacy (PGP)**

Implementing Domain-based Message Authentication, Reporting and Conformance (DMARC)

Explanation:

Implementing Pretty Good Privacy (PGP) is the correct answer. PGP provides authentication, message integrity, non-repudiation (through digital signatures), and privacy (encryption). It uses a combination of symmetric and asymmetric encryption to secure email communication, making it the most robust solution among the options provided.

Implementing DomainKeys Identified Mail (DKIM) is an email authentication method that helps detect email spoofing by allowing the receiver to check if the email was sent and signed by the domain it claims to be from. However, it does not provide encryption for the content of the email, making it less secure than PGP.

Implementing Sender Policy Framework (SPF) is an email authentication method that helps detect and prevent sender address forgery. While SPF can help prevent phishing and spam emails, it does not provide encryption for the content of the email, making it less secure than PGP.

Implementing Domain-based Message Authentication, Reporting and Conformance (DMARC) uses the results of SPF and DKIM checks to define rules for handling messages. While DMARC can help prevent phishing and spam emails, it does not provide encryption for the content of the email, making it less secure than PGP.

q_email_sec_phishing_01_secp8

Users in your organization receive email messages informing them that suspicious activity has been detected on their bank accounts. They are directed to click a link in the email to verify their online banking username and password. The URL in the link is in the .ru top-level DNS domain.

Which kind of attack has occurred?

Answers:

***Phishing**

Open SMTP relay

Virus

Buffer overflow

Explanation:

A phishing scam uses an email that purports to be from a trusted organization and asks you to verify personal information or send money. In a phishing attack:

- A fraudulent message (which appears to be legitimate) is sent to a target.
- The message requests that the target visit a fraudulent website (which also appears to be legitimate). Graphics, links, and web pages look almost identical to legitimate requests from legitimate websites.
- The fraudulent website requests that the victim provide sensitive information, such as an account number and password.

An SMTP relay is an email server that accepts mail and forwards it to other mail servers.

In a buffer overflow attack, a program (while writing data to a memory buffer) overruns the buffer's boundaries and writes data in adjacent memory addresses.

Viruses are types of malware that spread by infecting legitimate files on a computer system and are sometimes sent as email attachments.

q_email_sec_phishing_02_secp8

Which of the following BEST describes phishing?

Answers:

- ***A fraudulent email that claims to be from a trusted organization.**
- Malware that often uses email as its distribution mechanism.
- Unwanted and unsolicited email sent to many recipients.
- An email server that accepts mail and forwards it to other mail servers.

Explanation:

Phishing is a fraudulent email that claims to be from a trusted organization.

Spam is unwanted and unsolicited email sent to many recipients.

A virus is malware that often uses email as its distribution mechanism.

An SMTP relay is an email server that accepts mail and forwards it to other mail servers.

q_email_sec_phishing_03_secp8

Which of the following would you do to help protect against phishing?

Answers:

- ***Only open emails if you recognize the sender.**
- Don't post your full email address anywhere on the web.

Don't click on an unsubscribe link at the bottom of an unsolicited email.

In the email client, disable preview screens.

Explanation:

To protect against phishing:

Check the email header information to see more info about the sender and the links that are in the email.

Only open emails if you recognize the sender.

Check the actual link destination within emails to verify that they go to the correct URL and not a spoofed one.

Do not click on links in emails. Instead, type the real URL into the browser. You could also look up the website in a search engine.

Verify that HTTPS is used when going to e-commerce sites. HTTPS requires a certificate that matches the server name in the URL that is verified by a trusted certificate authority (CA). You can also look for the lock icon to verify that HTTPS is used.

Implement phishing protections within your browser.

To control spam:

Enable spam filters on client and email servers. Filter junk email by identifying safe senders (whitelists), blocked senders (blacklists), countries to block email from, and languages to block.

Enable antivirus scanning for attachments on the client and email servers.

In the email client, disable preview screens. An email can have links for active items that can report back to the spammer.

Don't click on an unsubscribe link at the bottom of an unsolicited email. Doing this verifies to the spammer that the email address is a current and active email address. Only unsubscribe from trusted organizations.

Install server-level, anti-spam software on the email server.

Don't post your full email address anywhere on the web. Spammers use software to scan websites to find email addresses and then add them to their email lists for spamming.

q_email_sec_phishing_04_secp8

An accounts payable clerk received an email requesting payment information for materials for an ongoing project. The email appears to be from a known vendor.

Before giving the information over, what should the clerk protect against?

Answers:

Typosquatting

Coercion

***Phishing**

Consensus technique

Explanation:

Phishing is a combination of social engineering and spoofing. It persuades or tricks the target into interacting with a malicious resource disguised as a trusted one.

Typosquatting means that the threat actor registers a domain name very similar to a real one, hoping that users will not notice the difference and assume they are browsing a trusted site.

Coercion or the use of urgency refers to the intimidation of the target with a bogus appeal to authority or penalty, such as getting fired or not acting quickly enough to prevent some dire outcome.

The persuasive or consensus technique attempts to convince the target that the request is natural and it would be impolite or somehow odd to refuse.

q_email_sec_smime_secp8

Which of the following mechanisms can you use to add encryption to email? (Select two.)

Answers:

***PGP**

***S/MIME**

HTTPS

Reverse DNS

Secure Shell

Explanation:

Use Pretty Good Privacy (PGP) or Secure MIME (S/MIME) to add encryption to emails.

HTTPS is used by web browsers to request data from web servers.

Secure Shell (SSH) is a secure remote management utility.

Reverse DNS can be used to verify the sending device's IP address included in an email. However, this does not add encryption to email messages.

q_email_sec_spam_01_secp8

If an SMTP server is not properly and securely configured, it can be hijacked and used maliciously as an SMTP relay agent.

Which activity could result if this happens?

Answers:

Salami attack

Data diddling

Virus hoax

***Spamming**

Explanation:

Attackers often distribute spam by hijacking a misconfigured SMTP server. SMTP servers that act as relay agents for unauthorized or external users can be easily employed to deliver spam. It is extremely important to properly configure SMTP servers to accept email only from authorized internal users.

A salami attack is an attack where small amounts of information, data, or valuables are taken over a period of time. The result is to construct or obtain data or property of great value. A common example of a salami attack is to deposit the fractions of cents from an accounting program into a numbered account. Eventually, the fraction deposits total a significant sum.

Data diddling is changing information during input, processing, output, or storage.

A virus hoax is a social engineering attack designed to play off of the fears of victims to convince them to perform malicious activities against themselves.

q_email_sec_spam_02_secp8

Which type of malicious activity can be described as numerous unwanted and unsolicited email messages sent to a wide range of victims?

Answers:

Brute force

Trojan horse

Hijacking

***Spamming**

Explanation:

Spamming is a type of malicious activity can be described as numerous unwanted and unsolicited email messages being sent to a wide range of victims. Spam itself is not usually malicious in nature. More often than not, it is advertising for some product or service. Unfortunately, spam accounts for 40 to 60 percent of all email traffic on the internet. Most of this activity is unsolicited.

A brute force attack is a hacking method that uses trial and error to crack passwords, login credentials, and encryption keys. It does not involve sending numerous unwanted and unsolicited email messages sent to a wide range of victims.

A trojan horse is a type of malware that downloads onto a computer disguised as a legitimate program. It does not involve sending numerous unwanted and unsolicited email messages sent to a wide range of victims.

Hijacking (or computer hijacking) is a type of network security attack in which the attacker takes control of computer systems, software programs and/or network communications. It does not involve sending numerous unwanted and unsolicited email messages sent to a wide range of victims.

q_email_sec_spam_03_secp8

An attacker sends an unwanted and unsolicited email message to multiple recipients with an attachment that contains malware.

Which kind of attack has occurred in this scenario?

Answers:

***Spam**

Open SMTP relay

Phishing

Repudiation attack

Explanation:

Spam is unwanted and unsolicited email messages sent to many recipients. Spam:

Can be benign, such as emails trying to sell products.

Can be malicious, such as emails containing phishing content, drive-by downloads, or malware.

Can contain malware as attachments.

Wastes bandwidth and could fill an inbox, resulting in a denial-of-service condition.

An open SMTP relay allows anyone to forward mail. An open SMTP relay can be used by spammers to send mail.

A phishing scam is an email pretending to be from a trusted organization, asking the recipient to verify personal information or send money.

In a repudiation attack, an attacker accesses your email server and sends spoofed emails to others, making them appear as if they came from you.

q_email_sec_spf_secp8

An organization is increasing security on corporate email exchanges after being a target in a whaling campaign.

Which of the following options is an email authentication method that helps detect and prevent sender address forgery?

Answers:

***Sender Policy Framework (SPF)**

Endpoint detection and response (EDR)

DomainKeys Identified Mail (DKIM)

Domain-based Message Authentication, Reporting and Conformance (DMARC)

Explanation:

Sender Policy Framework (SPF) is an email authentication method that helps detect and prevent sender address forgery, commonly used in phishing and spam emails.

An endpoint detection and response (EDR) product's aim is not to prevent initial execution, but to provide real-time and historical visibility into the compromise, contain the malware within a single host, and facilitate remediation of the host to its original state.

DomainKeys Identified Mail (DKIM) leverages encryption features to enable email verification by allowing the sender to sign emails using a digital signature.

Domain-based Message Authentication, Reporting and Conformance (DMARC) checks to define rules for handling messages, such as moving messages to quarantine or spam, rejecting them outright, or tagging the message.

11.0 Security Governance Concepts

11.1 Policies, Standards, and Procedures

As you study this section, answer the following questions:

What role do policies play in the framework of an organization?

Why is compliance to policies important?

How are standards different from policies?

Describe four different types of standards an organization may establish internally.

What problems does a playbook help an organization address?

The key terms for this section include:

Term	Definition
Policies	A strictly enforceable rule set that determines how a task should be completed.
Acceptable Use Policy (AUP)	A policy that governs employees' use of company equipment and Internet services. ISPs may also apply AUPs to their customers.
Information Security Policies	A document or series of documents that are backed by senior management and that detail requirements for protecting technology and information assets from threats and misuse.
Business Continuity & Continuity of Operations Plans (COOP)	A collection of processes that enable an organization to maintain normal business operations in the face of some adverse event.
Disaster Recovery	A documented and resourced plan showing actions and responsibilities to be used in response to critical incidents.
Software Development Life Cycle (SDLC)	The processes of planning, analysis, design, implementation, and maintenance that often govern software and systems development.
Guidelines	Best practice recommendations and advice for configuration items where detailed, strictly enforceable policies and standards are impractical.

Standards	Expected outcome or state of a task that has been performed in accordance with policies and procedures. Standards can be determined internally or measured against external frameworks.
Procedures	Detailed instructions for completing a task in a way that complies with policies and standards.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	4.6 Given a scenario, implement and maintain identity and access management. Multifactor authentication Password concepts Length Complexity Reuse Expiration 5.1 Summarize elements of effective security governance. Guidelines Policies Acceptable use policy (AUP) Information security policies Business continuity Disaster recovery Incident response Software development lifecycle (SDLC) Change management Standards

	Password Access control Physical security Encryption Procedures Playbooks External considerations Regulatory Legal Industry Local/regional National Global Monitoring and revision Types of governance structures Boards Committees Government entities Centralized/decentralized

11.1.1 Program Management and Oversight Overview (Lesson Video)

Transcript:

A critical component of any Information Security plan is proper program management and oversight. This ensures that all security controls put in place are being implemented and working properly. In this lesson, we'll look at some of the key elements of effective security governance, including organizational standards, external considerations, and ongoing monitoring and revision of the security plan.

A proper security plan will include policies, procedures, guidelines, and standards. Policies are essentially organizational rules that must be followed by employees. A common example is an Acceptable Use Policy. Procedures outline how

certain functions should be performed. Guidelines are designed to provide support and additional information on policies and procedures. Standards define how the policies are implemented.
For example, an organization may have a policy that access control must be implemented on certain data types. The organization would then implement standards that define who can access the data, how they can access it, and how access is monitored.
Password policies are typically defined in an organization. The standards define the length and complexity of the password, how often a password can be reused, and how often the password should be changed.
For example, the standards might state that the password should be a minimum of 8 characters, including upper and lowercase, numbers, and symbols, and that there should not be a set time to change the password. The standard can even define that multi-factor authentication should be used.
Some other common standards an organization should have defined include physical security measures such as cameras, physical access control, and security guard schedules and placements. To protect sensitive data, encryption standards should also be defined and implemented throughout the organization.
External considerations must be looked at when establishing internal policies. Perhaps the biggest external consideration is any laws that apply to the organization.
For example, in the health industry, the Health Insurance Portability and Accountability Act, or HIPAA, establishes laws and regulations that must be followed by any health organization. These laws and regulations define how data is secured, who can access patient data, and more. When internal policies are established, they must adhere to the regulations established by the law.
Aside from regulatory and legal compliance, we also need to consider any industry standards that may be in place. For example, in the IT field, the National Institute of Standards and Technology, or NIST, publishes various industry standards. While these aren't laws or regulations, these industry standards are put into place to define specific practices that should promote performance and efficiency. While some standards are globally accepted, others differ between countries, states, and even between cities.
Monitoring and updating of all policies and standards should take place on a regular basis. As new technologies come out, new laws and industry standards will be released. It's up to the organization to review these and update their internal policies and standards as needed.
That'll wrap up this lesson on program management and oversight. In this lesson, we first went over the differences in standards, policies, procedures, and guidelines. Standards define how policies should be implemented and are a core component of any security governance plan. We then looked at some external factors that should be considered when developing a security plan. These include legal and regulatory compliance, industry standards, and even global, national, and local standards and practices. We wrapped up by going over why it's important to monitor and revise the plans to stay current with industry and regulatory changes.

11.1.2 Program Management and Oversight Facts

Security governance is a critical aspect of an organization's overall security posture, providing a framework that guides the management of cybersecurity risks. It involves developing, implementing, and maintaining policies, procedures, standards, and guidelines to safeguard information assets and technical infrastructure. Security governance encompasses the roles and responsibilities of various stakeholders, emphasizing the need for a culture of security awareness throughout the organization. Governance frameworks must manage and maintain compliance with relevant laws, regulations, and contractual obligations while supporting the organization's strategic objectives. Effective security governance also involves continuous monitoring and improvement to adapt to evolving threats and changes in the business and regulatory environment.

This lesson covers the following topics:

- Governance and accountability
- Governance boards
- Government entities and groups
- Legal Environment

Governance and Accountability

Governance practices ensure organizations abide by all applicable cybersecurity laws and regulations to protect them from legal liability. Governance and organizational-level oversight must manage many legal risks, such as regulatory compliance requirements, contractual obligations, public disclosure laws, breach liability, privacy laws, intellectual property protection, and licensing agreements, and interpret and translate these legal requirements into operational controls to avoid legal trouble, act ethically, and protect the organization.

Guidelines for Implementing Governance

Follow these guidelines to support effective governance controls:

- Implement a governance structure that best supports the organization's objectives.
- Leverage expertise through committees to support decision-making.
- Establish a comprehensive list of policies, processes, standards, and guidelines.
- Implement change management programs to maintain control and promote transparency.
- Use automation and orchestration tools to improve consistency, reduce response times, and support compliance.

Governance Boards

Governance boards are crucial in ensuring an organization's effective security governance and oversight because they are responsible for setting strategic objectives, policies, and guidelines for security practices and risk management. Governance boards oversee the implementation of security controls, work closely with risk management teams to ensure compliance with relevant laws and regulations, and evaluate the security program's overall effectiveness. Governance boards drive organization-wide security practices through leadership, guidance, and accountability and ensure that security risks are effectively identified and mitigated. Governance boards unite executive management, security professionals, and stakeholders to ensure security is a top strategic priority aligned with the organization's objectives and values.

Centralized versus Decentralized

Centralized and decentralized security governance models aim to achieve the organization's security goals, protect assets, mitigate risks, and ensure regulatory compliance. Additionally, they recognize the importance of security and the need for collaboration between stakeholders and departments. However, there are notable differences between the two approaches. In centralized security governance, decision-making authority primarily rests with a single core group or department that establishes policies, procedures, and guidelines and makes important security-focused decisions. Resource allocation, including budget and personnel, is controlled by this group to promote consistency and standardization across the entire organization.

In contrast, decentralized security governance distributes decision-making authority to different groups or departments to facilitate security-focused decisions based on localized needs and priorities. Each unit has greater control over the allocation of security resources to allow greater adaptability and tailoring of security capabilities.

The choice between centralized and decentralized security governance depends on the organization's size, structure, culture, and risk appetite. Ultimately, the goal is to create a security governance model that effectively supports the organization's needs while balancing security risks.

Hybrid governance structures combine elements of both centralized and decentralized approaches. It aims to balance the advantages of centralized oversight and decentralized implementation. Under a hybrid system, specific security processes and

decisions are centralized, while others are delegated to business units or departments to facilitate the development of standardized policies at the enterprise level while providing flexibility and local control as warranted.

Committees and Boards

Governance boards depend upon governance committees to assist in complex decision-making situations. The governance board is typically composed of executives with the ultimate decision-making authority and is responsible for setting the strategic direction and policies of the organization. This responsibility often requires executives to make critical decisions regarding subjects outside their scope of expertise.

Committees are specialized groups comprised of subject matter experts, stakeholders, and representatives from relevant departments that focus on specific issues, such as security, risk management, audit, or compliance. They provide in-depth analysis, recommendations, and operational support to the governance board to provide them with the critical information needed to make effective decisions.

Governance boards and governance committees serve distinct roles within an organization's governance structure. Governance boards are typically composed of high-level executives and external stakeholders; whereas, governance committees are typically comprised of subject matter experts and operational leaders.

Data Governance Roles

Security governance relies heavily on specially designed and interdependent roles: owner, controller, processor, and custodian. Each role carries unique responsibilities that contribute to maintaining effective security oversight and control.

Role	Description
Owner	A high-ranking employee, like a director or a vice president, typically holds the owner role and is ultimately responsible for ensuring data is appropriately protected. The owner identifies what level of classification and sensitivity the data has, decides who should have access to it, and what level of security should be applied. In relation to governance, the owner provides strategic guidance to ensure that security policies align with business objectives.
Controller	The controller role closely relates to General Data Protection Regulation (GDPR) and identifies the purposes, conditions, and means of processing personal data. An individual, public authority, agency, or other body can fill the controller role. The controller ensures that data processing activities adhere to all legal requirements. In relation to governance, the controller helps maintain legal and regulatory compliance.
Processor	The processor is responsible for processing personal data on behalf of the controller and often represents cloud service providers (CSP) but could also be represented by vendors and business partners. Processors must maintain records of their processing activities, cooperate with supervisory authorities, and implement appropriate security measures to protect the data they handle. In relation to governance, the processor role ensures that data is handled securely and in accordance with the rules established by the owner and controller roles.
Custodian	The custodian, also known as the data steward, is responsible for the safe custody, transport, storage of the data, and implementation of business rules. The IT department typically represents the custodian role, and in relation to governance, the custodian role implements and enforces the security controls established by the data owner and controller and reports any issues indicative of a security incident.

Coordination among data owner, controller, processor, and custodian in managing and protecting data is crucial to ensure compliance with data protection regulations, establish clear responsibilities, and maintain data integrity and security.

Government Entities and Groups

At the government level, governance committees are often represented by specialized agencies. Several government agencies are associated with security governance and differ between countries and jurisdictions. A few examples of government agencies with security governance responsibilities include the following:

Agency	Description
Regulatory agencies	Regulatory agencies establish and enforce security standards, regulations, and guidelines. They oversee compliance with laws related to specific sectors such as finance, healthcare, telecommunications, and energy.
Intelligence agencies	Intelligence agencies gather and analyze information to identify and counteract potential security threats and provide this information to national-level government groups to steer national policy and military strategy.
Law enforcement agencies	Law enforcement agencies enforce laws and regulations related to public safety and security. They investigate and prosecute criminal activities, including cybercrimes and terrorist activities.
Defense and military organizations	Defense and military organizations are responsible for safeguarding national security and protecting the country from external threats. They develop strategies, policies, and capabilities to address physical security, border control, and defense-related cybersecurity.
Data protection authorities	Data protection authorities focus on protecting personal data and privacy rights. They enforce data protection regulations and provide guidance on the best practices for securing personal information.
National cybersecurity agencies	National cybersecurity agencies focus on protecting critical infrastructure, government networks, and national cybersecurity interests. They develop cybersecurity strategies, coordinate incident response, and provide guidance on cybersecurity practices for government entities and private organizations.

Legal Environment

Governance committees ensure their organizations abide by all applicable cybersecurity laws and regulations to protect them from legal liability. The governance committee must address these external considerations in the strategic plan for the organization.

Governance committees must manage many legal risks, such as regulatory compliance requirements, contractual obligations, public disclosure laws, breach liability, privacy laws, intellectual property protection, licensing agreements, and many others. Cybersecurity governance committees must interpret and translate these legal requirements into operational controls to avoid legal trouble, act ethically, and protect the organization.

The key frameworks, benchmarks, and configuration guides may be used to demonstrate compliance with a country's legal/regulatory requirements or with industry-specific regulations. *Due diligence* is a legal term meaning that responsible persons have not been negligent in discharging their duties. Negligence may create criminal and civil liabilities. Many countries have enacted legislation that criminalizes negligence in information management. In the United States, for example, the Sarbanes-Oxley Act (SOX) mandates the implementation of risk assessments, internal controls, and audit procedures. The Computer Security Act (1987) requires federal agencies to develop security policies for computer systems that process confidential

information. In 2002, the Federal Information Security Management Act (FISMA) was introduced to govern the security of data processed by federal government agencies.

Some regulations have specific cybersecurity control requirements; others simply mandate "best practice," as represented by a particular industry or international framework. It may be necessary to perform mapping between different industry frameworks, such as NIST and ISO 27K, if a regulator specifies the use of one but not another. Conversely, the use of frameworks may not be mandated as such, but auditors are likely to expect them to be in place as a demonstration of a strong and competent security program.

Global Law

As information systems become more interconnected globally, many countries have enacted laws with broader, international reach. Some examples include the General Data Protection Regulation (GDPR) and California Consumer Privacy Act (CCPA) which both act to protect the privacy of the constituents associated with each respective law irrespective of geopolitical boundaries.

Personal Data and the General Data Protection Regulation (GDPR)

Where some types of legislation address cybersecurity due diligence, others focus in whole or in part on information security as it affects privacy or personal data. Privacy is a distinct concept and requires that collection and processing of personal information be both secure and fair. Fairness and the right to privacy, as enacted by regulations such as the European Union's General Data Protection Regulation (GDPR) , means that personal data cannot be collected, processed, or retained without the individual's informed consent. *Informed consent* means that the data must be collected and processed only for the stated purpose, and that purpose must be clearly described to the user in plain language, not legal jargon. GDPR (ico.org.uk/for-organisations/guide-to-data-protection/guide-to-the-general-data-protection-regulation-gdpr) gives data subjects rights to withdraw consent, and to inspect, amend, or erase data held about them. Failure to comply with GDPR rules can result in incredibly large fines.

California Consumer Privacy Act (CCPA)

The CCPA provides California residents the right to know what personal information businesses collect about them, the purpose of collecting this data, and with whom they share it. It protects California residents' rights to access their personal information, delete it, or opt out of its sale. Organizations must inform consumers about the categories of personal information they collect and the purposes for which the information will be used. The CCPA applies to any organization, regardless of its location, that provides goods or services to California residents; has gross annual revenues over $25 million; buys or sells the personal information of 50,000 or more consumers, households, or devices; or derives 50% or more of annual revenues from selling personal information.

Varonis's blog contains a useful overview of privacy laws in the United States (varonis.com/blog/us-privacy-laws).

Regulations and National, Local, Regional and Industry Laws

Many countries have national-level laws to support effective cybersecurity practices and protect citizen data. The scope and detail of these laws varies significantly from one country to another, but organizations must comply with the laws in all the jurisdictions where they operate.

Examples in the United States include the Health Insurance Portability and Accountability Act (HIPAA), Gramm-Leach-Bliley Act (GLBA), and Federal Information Security Management Act (FISMA). The United Kingdom's national laws include the Data Protection Act 2018 and the Network and Information Systems (NIS) Regulations 2018. Canada enforces a privacy law called Personal Information Protection and Electronic Documents Act (PIPEDA), India regulates the IT industry with the Information Technology Act 2000, and Australia enforces the Privacy Act 1988. While it is not necessary to understand the details of each of these laws, it is important to understand that this complicated legal framework greatly influences the functional elements of a cybersecurity program.

While most cybersecurity laws typically have national or international scope due to the global nature of the internet, there are also laws and regulations with a more local or regional reach. These laws may be specific to states, provinces, or even cities, particularly in larger countries like the United States. Two important examples include the New York Department of Financial Services (DFS) Part 500 Cybersecurity Regulation and the Massachusetts 201 CMR 17.00 .

Industry-specific cybersecurity laws and regulations govern how data should be handled and protected. Here are a few key examples to help highlight that cybersecurity is a significant concern across all sectors of industry and is protected by a complicated matrix of laws that must be accommodated by cybersecurity operations and organizational governance:

Description of the Table

Sector	Laws
Healthcare	Health Insurance Portability and Accountability Act (HIPAA) (United States) The General Data Protection Regulation (GDPR) (European Union)
Financial Services	Gramm-Leach-Bliley Act (GLBA) (United States) Payment Card Industry Data Security Standard (PCI DSS) (Contractual obligation)
Telecommunications	Communications Assistance for Law Enforcement Act (CALEA) (United States)
Energy	North American Electric Reliability Corporation (NERC) (United States and Canada)
Education & Children	Family Educational Rights and Privacy Act (FERPA) (United States) Children's Internet Protection Act (CIPA) (United States) Children's Online Privacy Protection Act (COPPA) (United States)
Government	Federal Information Security Modernization Act (FISMA) (United States) Criminal Justice Information Services Security Policy (CJIS) (United States) The Government Security Classifications (GSC) (United Kingdom)

Cybersecurity regulations are legal rules and guidelines formulated by governments and regulatory bodies to safeguard digital information and systems from cyber threats. They set standards for protecting data confidentiality, integrity, and availability, particularly sensitive and personal information. Regulations cover diverse capabilities, including data protection, network and information systems security, data breach notifications, digital identity verification, and many others. Businesses, government agencies, organizations, and executives must work diligently to comply with these regulations or risk significant fines and imprisonment.

Cybersecurity regulations aim to protect consumer privacy rights, ensure the security of the financial system, uphold the stability and trustworthiness of the Internet and digital economy, and protect critical national infrastructure from cybercrime. The applicability of regulations depends on factors such as the industry the organization operates within, the types of data it handles, and the regions where it conducts business. Here are a few key examples, several of which have been previously mentioned:

General Data Protection Regulation (GDPR)

California Consumer Privacy Act (CCPA)

Health Insurance Portability and Accountability Act (HIPAA)

Federal Information Security Management Act (FISMA)

Network and Information Systems (NIS) Directive

Cybersecurity Maturity Model Certification (CMMC)

Monitoring and Revision

The cybersecurity landscape is continually evolving. Consequently, organizations must ensure that their cybersecurity policies, procedures, standards, and legal compliance practices associated with legal and regulatory compliance are regularly monitored, evaluated, and updated. These responsibilities are generally managed via collaboration among diverse groups to review existing policies, procedures, and standards and ensure their effectiveness against current requirements. Routine audits, inspections, and assessments are commonly used to measure compliance levels and identify new risks. The results of compliance reports, technological changes, business processes, laws, or newly identified risks drive policy, procedure, and standards revisions. Regular training sessions help to inform employees of policy changes and ensure continued compliance.

Additionally, organizations must maintain awareness of any changes in cybersecurity legislation in their jurisdictions, including international, national, regional, or industry-specific laws. Effective monitoring and revision of cybersecurity policies, procedures, standards, and legal compliance practices is a dynamic, cyclical process requiring diligence, foresight, and proactive strategies.

11.1.3 Policies, Standards, and Procedures

Policies, standards, and procedures are three key components that form the foundation of an organization's security program. Policies are high-level, authoritative documents defining the organization's security commitment. Standards are more specific than policies and specify the methods used to implement technical and procedural requirements. Procedures are detailed, step-by-step instructions describing how to complete specific tasks and align to the requirements provided in standards. Procedures provide clear directions for individuals to perform their job duties consistently, securely, and efficiently.

This lesson covers the following topics:

Policies

Standards

Procedures

Policies

Organizational policies are vital in establishing effective governance and ensuring organizational compliance. They form the framework for operations, decision-making, and behaviors, setting the rules for a compliant and ethical corporate culture. Governance describes the processes used to direct and control an organization, including the processes for decision-making and risk management. Policies are the outputs of governance. They establish the rules that frame decision-making processes, risk mitigation, fairness, and transparency. They set expectations for performance, align the organization around common goals, prevent misconduct, and remove inefficiencies.

Compliance describes how well an organization adheres to regulations, policies, standards, and laws relevant to its operation. Organizational policies are critical in ensuring compliance by integrating legal and regulatory requirements into daily operations. Policies define the rules and procedures for maintaining compliance and outline the consequences of noncompliance.

For example, an organization may have a data privacy policy that explains how it will maintain compliance with relevant laws to protect customer data. The policy details data collection, storage, processing, and sharing practices, including employee responsibilities, to ensure that all organization members understand and adhere to the rules. Organizational policies help facilitate compliance assessments through internal and external audits as policies provide a roadmap auditors follow to determine whether an organization is operating as it claims and is successfully satisfying its regulatory obligations.

Common Organizational Policies

Acceptable Use Policy (AUP) — This policy outlines the acceptable ways in which network and computer systems may be used by defining what constitutes acceptable behavior by users. AUPs typically address browsing behavior, appropriate content, software downloads, and handling sensitive information. The goal of an AUP is to ensure that users do not engage in activities that could harm the organization or its resources. Also, the AUP should detail the consequences for non compliance, including details regarding how compliance is monitored and require employees to acknowledge their comprehension of the AUP's rules via signature.

Information Security Policies — These are policies created by an organization to ensure that all information technology users comply with rules and guidelines related to the security of the information stored within the environment or the organization's sphere of authority.

Business Continuity & Continuity of Operations Plans (COOP) — Business continuity and COOP policies focus on the critical processes that must remain operational during and after a substantial disruption, like a natural disaster or a cyberattack.

Disaster Recovery — These policies detail the steps required to recover from a catastrophic event such as a natural disaster, major hardware failure, or a significant security breach. The goal is to restore operations as quickly and efficiently as possible.

Incident Response —This policy outlines the processes to be followed after a security breach or cyberattack occurs. It details the steps for identifying, investigating, controlling, and mitigating the impact of incidents, including procedures for communicating about the incident to internal and external sources.

Software Development Life Cycle (SDLC) —SDLC policies govern software development within an organization. These policies provide a structured plan detailing the stages of development from initial requirement analysis to maintenance after deployment. It ensures that all software produced meets the organization's efficiency, reliability, and security standards.

Change Management —Change management policies outline how changes to IT systems and software are requested, reviewed, approved, and implemented, including all documentation requirements.

Guidelines

Guidelines describe recommendations that steer actions in a particular job role or department. They are more flexible than policies and allow greater discretion for the individuals implementing them. Guidelines provide best practices and suggestions on achieving goals and completing tasks effectively and help individuals understand the required steps to comply with a policy or improve effectiveness.

An example of a guideline might be related to help desk support practices related to using email in response to employee support requests. The guideline may recommend specific language, tone, or response times but would allow for flexibility depending on the request's circumstances. While both policies and guidelines work to steer the actions and behaviors of employees, policies are mandatory and define strict rules, whereas guidelines provide recommendations and allow for more individual judgment and discretion. Regular review of guidelines is important to ensure they remain practical and relevant. Periodic assessments and updates to guidelines allow organizations to adapt them to changing technologies, business operations, emerging threats, and evolving industry standards.

Standards

Standards define the expected outcome of a task, such as a particular configuration state for a server, or performance baseline for a service. The selection and application of standards within an organization center on various dynamic elements such as regulatory requirements, business-specific needs, risk management strategies, industry practices, and stakeholder expectations.

Regulatory requirements are the primary driver for adopting standards. The unique operational differences between organizations dictate varying legal requirements and security, privacy, and data protection regulations. These requirements often require implementing specific standards or using guidelines for achieving compliance. The healthcare industry in the United States is a classic example, where providers must comply with stringent data protection and privacy standards established by the Health Insurance Portability and Accountability Act (HIPAA).

Depending on the nature of its operations, customer base, or technological dependencies, each organization must adopt standards that specifically address its needs. For example, organizations heavily utilizing credit card transactions will adopt the PCI DSS standard to safeguard the cardholder data environment (CDE). Similarly, cloud-reliant organizations often prefer adopting ISO/IEC 27017 and ISO/IEC 27018 to ensure safe and secure cloud operations.

Risk management strategies organizations stress the need for appropriate standards. Standards help identify, evaluate, and manage risks and fortify the organization's resilience against security incidents or data breaches. ISO/IEC 27001, for example, provides a comprehensive framework for an information security management system (ISMS) designed to aid organizations in effectively managing security risks. Adherence to industry best practices also influences the adoption of standards. Conforming to widely accepted and tested standards demonstrates an organization's commitment to upholding high security and data protection levels to bolster the organization's reputation and build trust with customers and partners. Stakeholder expectations (such as customers, partners, vendors, investors, executive boards, etc.) significantly influence the choice of standards too. Stakeholders view adherence to recognized standards as an affirmation of the organization's dedication to quality, security, and reliability.

The choice of standards should not be a procedural decision but instead a strategic one. The selection of standards involves a thoughtful balance of legal and regulatory requirements, business-specific needs, risk management protocols, industry best practices, and stakeholder expectations. Adopting standards impacts how a business operates, and selecting appropriate standards helps an organization run more effectively. In contrast, adopting the wrong standards, or failing to plan the implementation of standards properly, can have severe negative consequences.

Industry Standards

Common industry standards used by public and private organizations include the following:

ISO/IEC 27001 —An international standard that provides an i nformation s ecurity m anagement s ystem (ISMS) framework to ensure adequate and proportionate security controls are in place.

ISO/IEC 27002 —This is a companion standard to ISO 27001 and provides detailed guidance on specific controls to include in an ISMS.

ISO/IEC 27017 —An extension to ISO 27001 and specific to cloud services.

ISO/IEC 27018 —Another addition to ISO 27001, and specific to protecting personally identifiable information (PII) in public clouds.

NIST (National Institute of Standards and Technology) Special Publication 800-63 —A U S government standard for digital identity guidelines, including password and access control requirements.

PCI DSS (Payment Card Industry Data Security Standard) —A standard for organizations that handle credit cards from major card providers, including requirements for protecting cardholder data.

FIPS (Federal Information Processing Standards) —FIPS are standards and guidelines developed by NIST for federal computer systems in the U nited States that specify requirements for cryptography.

Common industry standards such as these play a significant role in auditing by providing a benchmark for evaluating organizational compliance and security practices. Standards such as ISO 27001, NIST SP800-63, PCI DSS, and FIPS provide comprehensive details and requirements for information security, risk management, data protection, and privacy. Auditing against these standards helps organizations assess their adherence to best practices, identify gaps or vulnerabilities, and demonstrate their commitment to maintaining a secure and compliant environment.

Internal Standards

Organizations also establish internal standards to ensure the safety and integrity of operations and protect valuable resources such as data, intellectual property, and hardware. Internal standards provide consistent descriptions to define and manage important organizational practices. Standards differ from policies in a few ways. A simplistic view of the differences between the two is that standards focus on implementation, whereas policies focus on business practices.

Password standards describe the specific technical requirements required to design and implement systems, including how passwords are managed within those systems to ensure that different systems can interoperate and use consistent password-handling methods.

Hashing Algorithms —D efines requirements for the hash functions used to store passwords.

Password Salting —Defines the methods used to protect password hashes to protect them from rainbow table attacks.

Secure Password Transmission —Defines the methods for secure password transmission, including details regarding appropriate cipher suites.

Password Reset —Defines appropriate identity verification methods to protect password reset requests from exploitation.

Password Managers —Defines the requirements for password managers that organizations may choose to incorporate.

Access control standards ensure that only authorized individuals can access the systems and data they need to do their jobs to protect sensitive information and help prevent accidental changes or damage. Internally developed access control standards typically include the following elements:

Access Control Models —Defines appropriate access models for different use cases. Examples include role-based access c ontrol (RBAC), discretionary access control (DAC), and mandatory access control (MAC), among others.

User Identity Verification —Defines acceptable methods to verify identities before granting access. Examples include simple passwords, security tokens, biometric data, and other methods.

Privilege Management —Defines the methods for managing user privileges to ensure they have the minimum required access.

Authentication Protocols —Defines specific acceptable authentication protocols, such as Kerberos, OAuth, or SAML.

Session Management —Defines allowable session management practices, including requirements for session timeouts, secure generation and transmission of session cookies, and other similar requirements.

Audit Trails —Defines mandatory audit capabilities designed to assist with identifying and investigating security incidents.

Physical security standards protect datacenters, computer rooms, wiring closets, cabling, hardware, and infrastructure comprising the IT environment and the people who use and maintain them. Some examples include the following :

Building Security —Methods for securing facilities, including card access systems, CCTV surveillance, and security personnel.

Workstation Security —Standards for physically securing laptops or other portable devices.

Datacenter and Server Room Security —Define s requirements for card access, biometric scans, sign-in/sign-out logs, and escorted access for visitors.

Equipment Disposal —Defines requirements for securely disposing (or repurposing) equipment to ensure that sensitive data is irrecoverable.

Visitor Management —Defines the requirements for managing visitors, such as sign-in/sign-out procedures, visitor badges, and escorted access requirements.

Encryption protects data from unauthorized access, and it is vital for securing data both at rest (stored data) and in transit (data being transmitted). Encryption standards identify the acceptable cipher suites and expected procedures needed to provide assurance that data remains protected.

Encryption Algorithms —Defines allowable encryption algorithms, such as AES (Advanced Encryption Standard) for symmetric or ECC for asymmetric encryption.

Key Length —Defines the minimum allowable key lengths for different types of encryption.

Key Management —Defines how keys are generated, distributed, stored, and changed. It often includes requirements for using secure key management systems, procedures for regularly changing keys, and procedures for revoking them if they are compromised.

Procedures

Policies and guidelines set a framework for behavior. Procedures define step-by-step instructions and checklists for ensuring that a task is completed in a way that complies with policy.

Playbooks

Playbooks are essential to establishing and maintaining organizational procedures by establishing a central repository of well-defined, standardized strategies and tactics. They guide personnel to ensure consistency in operations and improve quality and effectiveness.

Playbooks facilitate knowledge sharing and continuity as employees move into new roles or leave the organization. Playbooks also mitigate risk by documenting critical procedures and preserving institutional knowledge. Playbooks help new team members quickly learn established processes while existing team members have a reference point for their tasks.

Moreover, playbooks act as a tool for quality assurance and continuous improvement. Clearly defining processes and the best practices to handle them makes it easier to identify and improve problem areas. By using playbooks, organizations can monitor the use and effectiveness of procedures over time and modify them as necessary to foster an environment of continual learning and development.

Most significantly, playbooks are essential in incident response and crisis management because they detail emergency procedures and contingency plans vital to steering activities during an emergency or crisis. Playbooks help incident response teams make quick decisions and work more effectively under stress, leading to more resilient operations and reducing the likelihood and impact of major security incidents.

Several best practice guides and frameworks are available to assist in developing playbooks, such as The MITRE ATT&CK framework https://attack.mitre.org , NIST Special Publication 800-61 https://csrc.nist.gov/publications/detail/sp/800-61/rev-2/final , and Open Source Security Automation (OSSA) https://www.opensecurityandsafetyalliance.org/About-Us .

11.1.4 Apply Appropriate Polices and Regulations

11.1.5 Practice Questions (Section Quiz)

q_proj_mgmt_oversight_ccpa_secp8

You are a data privacy officer for a tech company based in the United States. The company is planning to expand its services to California.

Which of the following legal regulations should be your primary focus for ensuring data privacy compliance?

Answers:

General Data Protection Regulation (GDPR)

Health Insurance Portability and Accountability Act (HIPAA)

***California Consumer Privacy Act (CCPA)**

Federal Information Security Management Act (FISMA)

Explanation:

California Consumer Privacy Act (CCPA) is the correct answer. The California Consumer Privacy Act (CCPA) gives California residents more control over the personal information that businesses collect about them. If the company is expanding its services to California, it must ensure compliance with the CCPA to avoid potential legal issues.

The General Data Protection Regulation (GDPR) applies to the processing of personal data of individuals who are in the European Union. While it's a comprehensive and strict regulation, it would not be the primary focus for a company expanding its services to California.

The Health Insurance Portability and Accountability Act (HIPAA) applies to entities that handle protected health information. Unless the tech company is dealing with health information, this would not be the primary focus.

The Federal Information Security Management Act (FISMA) applies to federal agencies and companies that contract with the government. Unless the tech company is dealing with government contracts, this would not be the primary focus.

q_proj_mgmt_oversight_centralized_secp8

An organization is restructuring its IT governance framework to improve its cybersecurity strategy. The organization has several distributed offices across various geographical regions, each having a unique set of IT policies and infrastructure.

The cybersecurity lead aims to increase control and consistency over the security practices in each office while retaining some autonomy for the individual offices to manage their specific risks.

Which governance structure aligns with the objectives of the cybersecurity lead and effectively mitigates risks associated with the security practices at each office?

Answers:

***Centralized governance with an advisory board**

Decentralized governance with an executive committee

Change Control Board (CCB)

Centralized governance with a steering committee

Explanation:

Centralized governance involves standardizing IT policies and practices across the organization, increasing control and consistency, which is the main aim of the cybersecurity lead in the given scenario.

Decentralized governance would allow each office to independently manage its IT policies and practices, which would not help the organization achieve control and consistency over security practices.

CCB primarily deals with assessing, approving, or rejecting proposed changes to a project or system. While a CCB can be a component of IT governance, it does not serve as a comprehensive governance structure.

Steering committees generally make strategic decisions at a higher level and may not be as involved in addressing specific issues the way an advisory board would be.

q_proj_mgmt_oversight_committee_secp8

Which of the following BEST describes a governance committee in the context of security governance?

Answers:

A group of high-ranking executives responsible for setting the strategic direction and policies of the organization.

***A specialized group comprised of subject matter experts, stakeholders, and representatives from relevant departments that focus on specific issues, such as security, risk management, audit, or compliance.**

A group of external stakeholders responsible for evaluating the security program's overall effectiveness.

A group of individuals responsible for the allocation of security resources and decision-making based on localized needs and priorities.

Explanation:

A governance committee is a specialized group that focuses on specific issues and provides in-depth analysis, recommendations, and operational support to the governance board.

A group of high-ranking executives responsible for setting the strategic direction and policies of the organization is incorrect because it describes the role of a governance board, not a governance committee. While both are important to an organization's governance structure, they serve distinct roles.

A group of external stakeholders responsible for evaluating the security program's overall effectiveness is incorrect because it describes a part of the role of a governance board, not a governance committee. Governance boards are responsible for evaluating the security program's overall effectiveness, among other duties.

A group of individuals responsible for the allocation of security resources and decision-making based on localized needs and priorities is incorrect because it describes a characteristic of decentralized security governance, not a governance committee. In a decentralized model, decision-making authority and resource allocation are distributed to different groups or departments.

q_proj_mgmt_oversight_decentralized_secp8

A nationwide company realizes its current standardized approach to security is not working. The different company business units need more autonomy and the ability to make decisions that meet their local needs and priorities.

What type of security governance should they follow?

Answers:

***Decentralized security governance**

Centralized security governance

Governance committees

Data protection authorities

Explanation:

Decentralized security governance distributes decision-making authority to different groups or departments to facilitate security-focused decisions based on localized needs and priorities.

In centralized security governance, decision-making authority primarily rests with a single core group or department that establishes policies, procedures, and guidelines and makes important security-focused decisions.

Specialized groups, such as subject matter experts, stakeholders, and representatives from relevant departments, comprise governance committees that focus on specific issues, such as security, risk management, audit, or compliance.

Data protection authorities focus on protecting personal data and privacy rights. They enforce data protection regulations and provide guidance on the best practices for securing personal information.

q_proj_mgmt_oversight_gdpr_secp8

Under the General Data Protection Regulation (GDPR), which of the following statements is correct regarding the rights of data subjects?

Answers:

***Data subjects have the right to be forgotten, but this is limited to information that is no longer necessary for the purpose it was collected.**

Data subjects have the right to data portability, but only within the same industry.

Data subjects have the right to access their personal data, but they must pay a fee for this service.

Data subjects have the right to rectification, but only within 30 days of data collection.

Explanation:

Data subjects have the right to be forgotten, but this is limited to information that is no longer necessary for the purpose it was collected is the correct answer. Under the GDPR, data subjects have the right to be forgotten, also known as the right to erasure. This means they can request the deletion or removal of personal data where there is no compelling reason for its continued processing. This includes situations where the data is no longer necessary in relation to the purpose for which it was originally collected or processed.

The right to data portability allows data subjects to obtain and reuse their personal data across different services, not just within the same industry. They have the right to move, copy or transfer personal data easily from one IT environment to another in a safe and secure way.

Under the GDPR, data subjects have the right to access their personal data free of charge. This includes the right to obtain a copy of their personal data, as well as other supplementary information.

The right to rectification means that data subjects can have their personal data corrected if it is inaccurate or incomplete. There is no specific time limit, such as 30 days, for this right under the GDPR.

q_proj_mgmt_oversight_global_law_secp8

As a cybersecurity professional, you are working for a multinational company that operates in multiple countries. The company is planning to launch a new product that collects user data for personalization features.

Which of the following legal considerations should be your primary focus?

Answers:

The local laws of the country where the company is headquartered.

The laws of the country where the majority of users are located.

The laws of the country where the data servers are located.

***The global laws that apply to data privacy and protection.**

Explanation:

The global laws that apply to data privacy and protection is the correct answer. As a multinational company, it's crucial to consider global laws that apply to data privacy and protection. This ensures that the company is compliant with all relevant laws, regardless of where its users are located or where its operations are based. It also helps to prevent potential legal issues that could arise from differences in data privacy laws between countries.

While the local laws of the country where the company is headquartered are important, they may not cover all the legal requirements for data privacy and protection in other countries where the company operates or where its users are located.

Focusing solely on the laws of the country where the majority of users are located may leave the company exposed to legal risks in other countries. It's important to consider the laws of all countries where the company has users.

While the laws of the country where the data servers are located are important, they may not fully cover the legal requirements for data privacy and protection in other countries where the company operates or where its users are located.

q_proj_mgmt_oversight_governance_committee_secp8

A multinational company discovered its existing cybersecurity policies were no longer adequate due to evolving cybersecurity threats and updated industry regulations.

The board of directors, comprising high-ranking executives, decided to review and revise the policies.

Who should the company involve in this process?

Answers:

Data custodian

Data processor

***Governance committee**

Regulatory agency

Explanation:

A governance committee is a specialized group comprised of subject matter experts, stakeholders, and representatives from relevant departments and focuses on specific issues such as security, risk management, audit, or compliance.

While a data custodian, or data steward, is responsible for the safe custody, transport, and storage of data, this role is more about the implementation of business rules rather than the revision of high-level policies.

The role of a data processor is mainly to process personal data on behalf of the controller.

While the company must consider the regulations set by regulatory agencies when revising its policies, it is not typically necessary to directly involve these agencies in the process.

q_proj_mgmt_oversight_guidelines_secp8

Which of the following is NOT a guideline for implementing effective governance controls?

Answers:

Implement a governance structure that best supports the organization's objectives.

Leverage expertise through committees to support decision-making.

Establish a comprehensive list of policies, processes, standards, and guidelines.

***Avoid using automation and orchestration tools to maintain control and promote transparency.**

Explanation:

Avoiding using automation and orchestration tools to maintain control and promote transparency is NOT a guideline. The guideline is to use automation and orchestration tools to improve consistency, reduce response times, and support compliance. Avoiding these tools would not be a guideline for implementing effective governance controls.

Implementing a governance structure that best supports the organization's objectives is indeed a guideline for implementing effective governance controls. It ensures that the governance structure aligns with the organization's goals and strategies.

Leveraging expertise through committees to support decision-making is a guideline for implementing effective governance controls. Committees provide a platform for subject matter experts to contribute their knowledge and insights, thereby enhancing the decision-making process.

Establishing a comprehensive list of policies, processes, standards, and guidelines is a guideline for implementing effective governance controls. These elements provide a clear framework for the organization's operations and ensure consistency and compliance.

q_proj_mgmt_oversight_hipaa_secp8

Which of the following cybersecurity laws and regulations is specifically designed to protect the privacy and security of health information in the healthcare industry?

Answers:

The Sarbanes-Oxley Act (SOX)

The Payment Card Industry Data Security Standard (PCI DSS)

***The Health Insurance Portability and Accountability Act (HIPAA)**

The Federal Information Security Management Act (FISMA)

Explanation:

The Health Insurance Portability and Accountability Act (HIPAA) is the correct answer. HIPAA is a federal law that required the creation of national standards to protect sensitive patient health information from being disclosed without the patient's consent or knowledge. It is specifically designed for the healthcare industry.

The Sarbanes-Oxley Act (SOX) is a law that sets requirements for all US public company boards, management, and public accounting firms. It does not specifically focus on the healthcare industry or the protection of health information.

The Payment Card Industry Data Security Standard (PCI DSS) is a set of security standards designed to ensure that all companies that accept, process, store or transmit credit card information maintain a secure environment. It does not specifically focus on the healthcare industry or the protection of health information.

The Federal Information Security Management Act (FISMA) is a United States federal law enacted in 2002 as Title III of the E-Government Act of 2002. The act recognized the importance of information security to the economic and national security interests of the United States. It does not specifically focus on the healthcare industry or the protection of health information.

q_proj_mgmt_oversight_processor_secp8

Your organization is implementing a new data governance model. You are tasked with assigning roles to various team members.

One of your colleagues is responsible for processing personal data on behalf of the controller, based on the controller's instructions.

Which data governance role BEST fits this colleague's responsibilities?

Answers:

Owner

Controller

***Processor**

Custodian

Explanation:

Processor is this is the correct answer. The processor processes personal data on behalf of the controller, based on the controller's instructions. This aligns directly with the role described in the question.

The owner is a high-ranking employee, like a director or a vice president, who is ultimately responsible for ensuring data is appropriately protected. They identify what level of classification and sensitivity the data has, decide who should have access to it, and what level of security should be applied. This does not align with the role described in the question.

The controller determines why and how personal data is collected, stored, and used. While the controller does have a role in processing data, the role described in the question is specifically following the controller's instructions, which aligns more with the processor role.

The custodian is responsible for the day-to-day management and protection of data. While they may handle data, they do not process it on behalf of the controller, which is the role described in the question.

q_proj_mgmt_oversight_stakeholders_secp8

An IT manager prepares a proposal to implement change management. Before being able to start the program, the manager needs support from key personnel within every department.

What key personnel does the manager need support from?

Answers:

Controller

Owner

***Stakeholders**

Processor

Explanation:

Stakeholders in change management are personnel with a vested interest in the change. Their participation fosters ownership and responsibility.

The controller role closely relates to the General Data Protection Regulation (GDPR) and identifies the purposes, conditions, and means of processing personal data. This position is not part of change management.

A high-ranking employee, like a director or a vice president, typically holds the owner role and is ultimately responsible for ensuring appropriate data protection. This position is not part of change management.

The processor is responsible for processing personal data on behalf of the controller and often represents Cloud Service Providers (CSP). However, vendors and business partners could also be representatives. This position is not part of change management.

q_pol_standards_procedures_audits_secp8

In a healthcare organization, the IT department conducts regular internal audits to ensure compliance with Health Insurance Portability and Accountability (HIPAA) regulations and to identify potential vulnerabilities.

During an audit, the IT team gathers evidence to evaluate the effectiveness of the implemented security controls and assess the overall security posture. The IT team uses questionnaires to obtain information from various departments and employees as part of the audit process.

What is the purpose of gathering evidence from internal audits and questionnaires?

Answers:

***Evaluate security effectiveness and identify areas for improvement.**

Obtain employee feedback on the company's security measures.

Implement new security policies based on survey results.

Ensure compliance with financial regulations.

Explanation:

The IT department evaluates the effectiveness of security controls and identifies areas for improvement by gathering evidence from internal audits and questionnaires. This evidence allows the team to make informed decisions about enhancing security posture.

Questionnaires may collect employee feedback, but the primary purpose of gathering evidence from internal audits and questionnaires is to assess security effectiveness, not solely to obtain feedback.

The IT department uses the evidence collected to assess existing security measures rather than implementing new policies solely based on survey results.

Evidence gathered from internal audits and questionnaires serves a broader purpose than just compliance with financial regulations. It aims to evaluate security effectiveness and identify areas for improvement across the financial institution.

q_pol_standards_procedures_aup_secp8

A newly hired chief information security officer (CISO) is implementing the National Institute of Standards and Technology (NIST) Cybersecurity Framework.

What first function would help the CISO better develop the company's security policies, such as acceptable use policy (AUP), and build out recommendations for security controls?

Answers:

Protect

***Identify**

Detect

Respond

Explanation:

The identify function in the National Institute of Standards and Technology's Cybersecurity Framework refers to developing security policies and capabilities. The CISO preparing policies and controls would fall under the identify function.

The second function of the NIST Cybersecurity Framework is protect, referring to the procurement, development, or deployment of IT assets and how to defend them against malicious actors.

The framework's third function is detect, which refers to ongoing, proactive monitoring to ensure that controls are effective and capable of protecting against new threats.

The fourth function of the framework is respond, determining how a company would identify, analyze, contain, and eradicate threats to systems and data security.

q_pol_standards_procedures_coop_01_secp8

A large technology company has recently experienced a significant system failure due to a cyberattack. The chief information security officer (CISO) is conducting a post-incident review to identify ways to improve the organization's resilience and recovery capabilities.

The CISO wants to focus on strategies that could have prevented the system downtime or minimized its duration and impact.

From a resilience and recovery standpoint in security architecture and continuity of operations planning (COOP), which of the following strategies would the CISO MOST likely recommend implementing to enhance the organization's ability to prevent or quickly recover from similar incidents in the future? (Select two.)

Answers:

Expand the IT team with more developers

Invest in a stronger firewall system

***Establish a redundant data center**

***Implement a detailed incident response plan**

Establish strong password policies and standards

Explanation:

An organization can notably strengthen its resilience and recovery capabilities by establishing a redundant data center. The redundant site swiftly takes over operations in case of a system failure or cyberattack, reducing downtime.

Formulating a detailed incident response plan is key to guaranteeing an effective, coordinated response to incidents. This plan specifies the procedures for identifying, reacting to, and recovering from security incidents.

Expanding the IT team could help if the new employees simply focused on cyber security issues. However, it is also the most expensive solution, and more team members may not be as effective as re-organizing the existing team or giving them the resources and tools to take care of the issue.

Investing in a stronger firewall system does not always guarantee that system failures due to a cyberattack will be significantly reduced. In this scenario, it would be wiser to first establish a redundant data center and implementing a more detailed incident response plan. Then, if that is ineffective, strengthening the firewall might be a solution.

Strengthening password policies and standards can help to prevent or reduce the occurrence of cyberattacks. However, in this scenario, the CISO made the correct decision to first address the issue by establishing a redundant data center and implementing a more detailed incident response plan.

q_pol_standards_procedures_coop_02_secp8

A cybersecurity team plans to improve the resilience of their organization's IT infrastructure.

The lead architect suggests implementing continuity of operations planning (COOP) to address potential disruptions and keep critical operations running during unexpected events.

What primary objective BEST describes the purpose of implementing COOP within an organization's security architecture?

Answers:

***It ensures continuous critical operations during unexpected disruptions.**

It prevents unauthorized access to sensitive data.

It monitors network traffic for malicious activities.

It provides immediate power backups during electrical outages.

Explanation:

COOP focuses on maintaining the continuity of an organization's critical operations during unexpected disruptions, ensuring minimal downtime and impact.

While data protection is a security concept, it is not the primary objective of COOP. Other mechanisms like encryption and access control lists focus on this goal.

Network monitoring is essential for security, but it is not the main objective of COOP. This function typically falls under intrusion detection systems (IDS) or intrusion prevention systems (IPS).

While power backups are crucial, they form a part of business continuity planning (BCP) and Disaster Recovery (DR) more than COOP. COOP encompasses a broader range of operations beyond just power supply.

q_pol_standards_procedures_coop_03_secp8

An earthquake occurs near the company HQ, causing severe damage in the area. The earthquake affected the building, which will not be usable for several weeks.

What plan will the company follow to maintain its business? (Select two.)

Answers:

***COOP**

***Disaster recovery**

Incident response

AUP

Playbook

Explanation:

The continuity of operations plan (COOP) focuses on the critical processes that must remain operational during and after a substantial disruption, like a natural disaster.

A disaster recovery plan details the steps required to recover from a catastrophic event such as a natural disaster. The goal is to restore operations as quickly and efficiently as possible.

The following will not help the company maintain its business in this scenario:

The incident response policy outlines the processes to follow after a security breach or cyberattack occurs.

An acceptable use policy (AUP) outlines how individuals may use network and computer systems by defining what constitutes acceptable behavior by users.

Playbooks are essential to establishing and maintaining organizational procedures by establishing a central repository of well-defined, standardized strategies and tactics. They guide personnel to ensure consistency in operations and improve quality and effectiveness.

q_pol_standards_procedures_coop_04_secp8

A nonprofit organization is working to create an integrated strategy that responds to potential disasters and ensures the continuation of essential functions across various scenarios, including budget constraints and prolonged disruptions.

Which approach would BEST address these multifaceted requirements?

Answers:

***Establish a COOP.**

Deploy a cold site.

Set up a warm site.

Implement a hot site.

Explanation:

Establishing a continuity of operations plan (COOP) offers a holistic approach that considers disaster recovery and the continuation of essential functions across different challenges.

Deploying a cold site is a specific strategy focusing on cost-effective recovery after a disaster but does not cover the comprehensive requirements for ensuring essential functions across various scenarios.

Setting up a warm site gears toward quicker recovery than a cold site but lacks the broad organizational resilience needed to address multiple scenarios, including prolonged disruptions.

Implementing a hot site centers on immediate recovery but falls short of providing a complete solution for the organization's wider continuity needs and budget considerations.

q_pol_standards_procedures_data_privacy_secp8

A company is reviewing its policies to ensure compliance with data privacy regulations. It wants to establish a policy that outlines the appropriate use of customer data.

What type of policy should the company focus on?

Answers:

***Data privacy policy**

Acceptable use policy (AUP)

Information security policy

Disaster recovery policy

Explanation:

The company is specifically concerned about compliance with data privacy regulations. Therefore, it should develop a data privacy policy outlining customer data handling to maintain compliance with relevant laws and data privacy protection.

An AUP focuses on defining acceptable behavior by users regarding network and computer systems; it may not specifically address data privacy.

An information security policy is broader and covers guidelines related to information security within the organization, including data privacy. However, this scenario needs a more specific data privacy policy.

Unrelated to data privacy, a disaster recovery policy focuses on recovering from catastrophic events or disruptions.

q_pol_standards_procedures_incident_response_secp8

A company merged with another company and is reviewing and combining both companies' procedures for incident response.

What should the joined companies have at the end of this preparation phase?

Answers:

***Incident response plan**

Communication plan

Playbook

Incident response lifecycle

Explanation:

An incident response plan lists the procedures, contacts, and resources for various incident categories available to responders. It covers expected or past incidents and the appropriate steps to respond accordingly.

A communication plan is part of the incident response plan that establishes clear lines of communication for reporting incidents and notifying affected parties as the management of an incident progresses.

A playbook is a data-driven standard operating procedure assisting analysts in detecting and responding to specific cyber threat scenarios. It is part of an incident response plan.

The incident response lifecycle is a seven-step process under which the preparation stage falls. It is not a document presented during the preparation phase.

q_pol_standards_procedures_iso_iec_secp8

A large multinational company adopts a new standard to enhance its information security management system. The company operates across different regions, so the chosen standard must be internationally recognized.

The company wants the standard to provide a comprehensive framework to ensure adequate and proportionate security controls.

Which of the following standards would be MOST suitable for the company's needs?

Answers:

***ISO/IEC 27001**

ISO/IEC 27018

NIST Special Publication 800-63

PCI DSS

Explanation:

ISO/IEC 27001 provides a comprehensive framework for an information security management system (ISMS), ensuring adequate and proportionate security controls. It is suitable for international use and ideal for a multinational company.

The ISO/IEC 27018 standard also pertains to information security, protecting personally identifiable information (PII) in public clouds. Although it may also be useful, it is less comprehensive than ISO/IEC 27001 for general information security management.

The NIST Special Publication 800-63 standard is a U.S. government standard for digital identity guidelines. While it may offer useful guidelines for parts of the company's security needs, it is less comprehensive than ISO/IEC 27001.

Payment Card Industry Data Security Standard (PCI DSS) is more specific for organizations that handle credit card transactions from major card providers.

q_pol_standards_procedures_password_salting_secp8

As a security analyst at a large corporation, you are tasked with reviewing and improving the company's password security measures.

Currently, the company uses a simple hashing algorithm to store passwords. You are considering four options to enhance password security.

Which of the following would be the MOST effective method to implement?

Answers:

Increase the minimum password length requirement

Implement password complexity requirements

***Implement password salting**

Implement a password expiration policy

Explanation:

Implementing password salting is the most effective method among the options. Salting involves adding a unique random string of characters to each password before it is hashed. This makes pre-computed hash attacks, such as rainbow table attacks, ineffective and significantly increases the difficulty of cracking the passwords, even if the hash values are somehow compromised.

Increasing the minimum password length requirement can improve security by making brute force attacks more difficult. However, it does not protect against other types of attacks, such as rainbow table attacks, and can lead to user frustration and poor password practices, such as writing down passwords.

Implementing password complexity requirements can also deter brute force attacks and make guessing passwords more difficult. However, like increasing password length, it does not protect against all types of attacks and can lead to poor password practices.

Implementing a password expiration policy can help limit the potential damage if a password is compromised. However, it can also lead to user frustration and poor password practices, such as making minor modifications to old passwords or writing down passwords. Furthermore, if a password is compromised, the attacker usually exploits it immediately, making the expiration policy less effective.

q_pol_standards_procedures_playbooks_secp8

A company's security team prepares a playbook as part of its business continuity planning. The playbook outlines various scenarios, including natural disasters, cyberattacks, and power outages, detailing how to minimize business interruption and swiftly restore systems.

Given the scenario, what is the primary function of the playbook within the company's business continuity plan?

Answers:

***Directing immediate response and recovery operations**

Predicting the occurrence of future disaster events

Eliminating the risk of natural disasters and cyberattacks

Training employees on how to prevent power outages

Explanation:

The playbook's role is to guide immediate response and recovery actions during a disruption. Playbooks provide step-by-step instructions for the security team, ensuring a swift, coordinated response to various scenarios outlined in the business continuity plan.

While playbooks include potential scenarios, they do not predict when these events will occur. Their purpose is to guide responses when such events happen.

Playbooks do not eliminate risks but prepare teams to manage and respond effectively.

While employee training can be a component of a comprehensive business continuity plan, it is not the primary purpose of a playbook. Playbooks manage responses during events, not prevent them.

q_pol_standards_procedures_session_management_secp8

As a security manager at a financial institution, you are reviewing the company's access control measures. You have identified potential areas of improvement and are considering four options to enhance access control security.

Which of the following would be the MOST effective method to implement?

Answers:

Implement biometric authentication

Increase password complexity requirements

***Improve session management**

Implement a two-factor authentication

Explanation:

Improving session management is the most effective method among the options. Good session management includes measures like session timeout, which logs a user out after a period of inactivity, and session invalidation, which ends the session when the task is completed or when the user logs out. This can prevent unauthorized access if a user leaves their device unattended or if a session token is compromised.

Implementing biometric authentication can enhance security by adding a layer of physical identity verification. However, it can be costly to implement, and there are potential privacy concerns. Moreover, it does not address issues such as session hijacking, where an attacker can gain control after authentication has occurred.

Increasing password complexity requirements can deter brute force attacks and make guessing passwords more difficult. However, it does not protect against attacks that occur after authentication, such as session hijacking or cross-site scripting attacks.

Implementing two-factor authentication can significantly improve security by requiring a second form of verification in addition to a password. However, like biometric authentication and password complexity requirements, it does not address attacks that occur after authentication.

11.2 Change Management

As you study this section, answer the following questions:

When is change management used, and what risks does it help mitigate?

Who should be involved in change management?

How do allow and deny lists help in change management?

What is the purpose of version control in change management?

The key terms for this section include:

Term	Definition
Stakeholders	A person who has a business interest in the outcome of a project or is actively involved in its work.
Dependencies	Resources and other services that must be available and running for a service to start.
Version control	The practice of ensuring that the assets that make up a project are closely managed when it comes time to make changes.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	1.3 Explain the importance of change management processes and the impact to security. Technical implications Allow lists/deny lists Restricted activities Downtime Service restart

	Application restart Legacy applications Dependencies Documentation Updating diagrams Updating policies/procedures Version control 5.1 Summarize elements of effective security governance. Policies Change management Procedures Change management Types of governance structures Boards 5.2 Explain elements of the risk management process. Risk analysis

11.2.1 Change Management (Lesson Video)

Transcript:

Change is inevitable in the IT field. Whether it's updating to new equipment or changing direction mid project, you're bound to come across a lot of changes!

In this video, we're going to talk about change management. This is just the method we use to ensure that changes are implemented as smoothly and effectively as possible.
Most organizations have an official approval process for change management. A business commonly uses change order forms to document these requests.
Change order forms are different for each company, but they typically ask for the change's purpose, scope, and extent, along with a risk analysis and rollback plan in case things don't go as expected.
So, after filling out your change order form, what's next? Well, first, it must be approved by the change board. A change board might consist of one person or many people who approve changes to the project. Board members might be managers, project supervisors, and maybe even the CEO. If you were developing this project for a customer instead of for in-house use, the customer would need to approve the changes as well.

The first thing the change board will want to know is why you want to make this change at all. You'll want to explain why the change is needed and whether it'll improve a current process, save money, or add additional functionality. You might also be asked to explain how it fits within the organization's current strategic focus. The change board will also want to know the scopeâ€”what exactly the proposed change will entail from start to finish. A scope has many components, but it should always include outcomes, cost, personnel, and systems.

Some other questions you'll need to have a ready answer for are: What are your desired outcomes? What exactly do you want to change? What are the desired deliverables? How will you know when the project is complete? The board will also obviously want to know how much this is all going to cost, whether in money, time, or resources.

You'll want to consider which personnel you'll need to implement the change. Will you need developers, technicians, or administrative staff? Be sure to include the contact information for a point person who can serve as the change board's primary contact for the project, if it's approved. It's also important to explain which existing systems will be impacted. Most likely, you'll be working alongside live production systems and any changes should be carefully planned out. Will there be downtime or potential conflicts? If so, you probably want to set up a sandbox to test the proposed changes before you implement them. As you can see, if there's literally anything you think you might need for your project, you want to include it in the scope.

Before you propose a change, you also want to analyze the potential risk. Yes, even small projects come with some risk. Be sure to ask yourself, "What could go wrong if we implement these changes?" After you think through that, the next obvious questions are: How are we going to avoid these problems? How difficult will it be to backtrack if things turn out worse than expected? Is the outcome worth the risk? If it turns out that the risks outweigh the rewards, you probably want to rethink your approach.

Now, before you start anything, make sure you get written approval for your changes. Written acceptance protects you, the change board, and the customer. This ensures that all of you have a complete understanding of the proposed changes and what they could entail. You want to avoid misunderstandings that could hurt your own or your organization's reputation or that might end up causing expensive problems.

Documentation is critical to any project from start to finish! During the implementation stage, you want to be sure to document all the changes you've made along the way. Include the specific approvals you've received. Once you're done, be sure to follow your organization's end user acceptance process. This ensures that someone who's going to be using the system verifies that it's working as expected. And be sure to document this as well.

That's it for this lesson. In this lesson, we discussed change management. We reviewed the information that's commonly needed for a change request. Then we went over the importance of documentation during a proposed change's approval and implementation phase.

11.2.2 Change Management Facts

Change management is a systematic approach to managing all changes made within an IT infrastructure. Its primary goal is to minimize risk and disruption while maximizing the value and efficiency of organizational changes. Change management relies on effective planning, testing, approval, and implementation of various changes ranging from minor updates to complicated system migrations. Change management must consider the potential impacts and dependencies of all proposed changes and mandate the development of contingency and rollback plans in case changes lead to unforeseen problems. Proper documentation and communication are also essential, ensuring that all relevant stakeholders understand the details of proposed changes and their implications. Change management programs promote a controlled progression of software and the IT infrastructure and contribute to its resilience and stability.

This lesson covers the following topics:

- Change management programs
- Factors driving change management
- Allowed and blocked changes
- Restarts, dependencies, and downtime
- Legacy systems and applications

Documentation and version control

Change Management Programs

Change management plays a vital role in an organization's security operations. It refers to a systematic approach that manages all changes made to a product or system, ensuring that methods and procedures are used to handle these changes efficiently and effectively. This helps minimize risks associated with the changes, ensuring they do not negatively impact the organization's security posture, service availability, or performance.

A non-comprehensive list of changes typically managed in a change management program includes the following:

- Software deployments
- System updates
- Software patching
- Hardware replacements or upgrades
- Network modifications
- Changes to system configurations
- New product implementations
- New software integrations
- Changes and refreshes to support environments

If not properly managed, these changes can introduce new vulnerabilities into the system, disrupt services, or negatively impact the organization's compliance status. A robust change management program allows all changes to be tracked, assessed, approved, and reviewed. Each change must include documentation, including details describing what will be changed, the reasons for the change, any potential impacts, and a rollback plan in case the change does not work as planned. Each change must be subject to risk assessment to identify potential security impacts. Appropriate personnel must approve changes before implementation to ensure accountability and ensure changes align with business priorities.

After implementations, changes must be reviewed and audited to ensure they have been completed correctly and achieved their stated outcome without compromising security. Systematic management of changes supports an organization's ability to reduce unexpected downtime and system vulnerabilities. Change management programs contribute to operational resilience by ensuring that changes support business objectives without compromising security or compliance.

A typical change management approval process involves several stages designed to ensure proper assessment and approval of change proposals. Change requests usually begin with submitting a request for change (RFC) that outlines the details of the proposed change, including its purpose, scope, and potential impact. The change request is reviewed by a designated change manager or committee that assesses its feasibility, risks, alignment with organizational objectives, and policy compliance. Following initial review, the change request undergoes a formal approval process involving relevant stakeholders, such as management, IT teams, and any impacted departments, to ensure consensus and authorization before the change is implemented. Throughout the process, documentation and communication are crucial in tracking the status and outcome of approved changes.

The implementation of changes should be carefully planned, with consideration for how the change will affect dependent components. For most significant or major changes, organizations should attempt to trial the change first. Every change should be accompanied by a rollback (or remediation) plan so that the change can be reversed if it has harmful or unforeseen

consequences. Changes should also be scheduled sensitively if they are likely to cause system downtime or other negative impacts on the workflow of the business units that depend on the IT system being modified. Most networks have a scheduled maintenance window period for authorized downtime. When the change has been implemented, its impact should be assessed, and the process reviewed and documented to identify any outcomes that could help future change management projects.

Factors Driving Change Management

Change management requires the expertise of individuals from various parts of an organization to oversee and implement changes effectively. Examples include IT professionals with technical knowledge, business leaders with operational knowledge, and compliance officers with legal expertise. The involvement of these stakeholders (which includes anyone with a vested interest in the change or project being implemented or developed) facilitates a comprehensive review of proposed changes, helping to identify non-obvious risks and identify effective implementation plans that minimize risks and business disruptions. Additionally, including diverse stakeholders promotes acceptance and adoption of the changes because they were involved in the planning and decision-making process. Stakeholder participation fosters ownership and responsibility, which are crucial for successful change implementation.

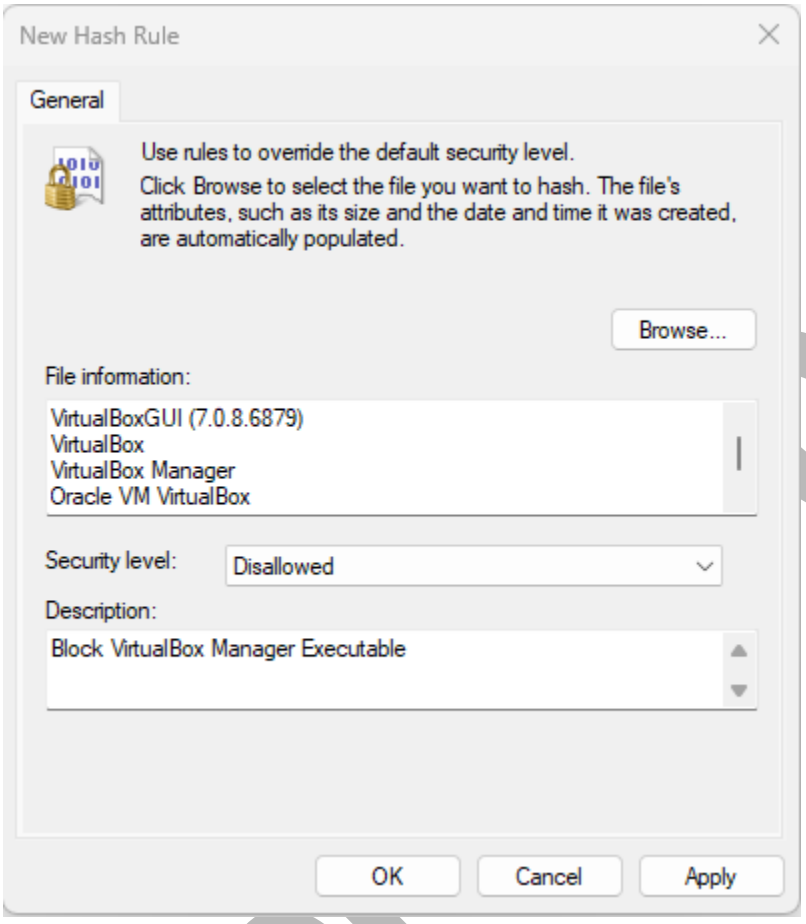
Ownership in change management refers to individuals or groups primarily responsible for implementing a specific change. Owners can be project managers, team leaders, or anyone responsible for the change. Owners are accountable for ensuring that the change is implemented as planned, risks are managed effectively, and there's a clear plan for communication and training associated with the change. They also ensure that all stakeholders appropriately review and approve the proposed change. Stakeholders in the change management process describe the individuals or groups impacted (or interested) in the change and include employees, managers, the Change Advisory Board (CAB), and sometimes even customers, vendors, and partners. Stakeholder engagement is critical to successful change management because keeping stakeholders informed about changes, understanding their concerns, and addressing their needs improves the likelihood of the change being accepted and implemented smoothly.

Allowed and Blocked Changes

Allow lists and deny lists play a significant role in change management practices and can reference two different viewpoints. One scenario views allow and deny lists in relation to change types or from a different view. Allow and block lists describe software restriction approaches designed to control computer software. In terms of change management, an allow list describes a list of approved software, hardware, and specific change types (such as routine or low-risk changes) that are not required to go through the entire change management process. An allow list may also include specific individuals with change management approval authority. Allow lists help streamline change management by reducing the time and effort required for trusted or preauthorized changes. Allow lists must be updated via regular reviews to stay corrected with changing organizational needs.

A deny list includes explicitly blocked software, hardware, and specific change types. The block list might include software and hardware with known security or compatibility issues, high-risk or high-impact changes that must always go through the full change management process, or individuals who are not authorized to implement or approve changes. In this regard, deny lists help prevent unauthorized or risky changes from being implemented. They can serve as a security measure to clearly identify off-limits change types so there is no room for negotiation or misinterpretation.

Allow and block lists also refer to technical controls that exist in a few different contexts, including access controls, firewall rules, and software restriction mechanisms. Allow and block lists can impact change implementation by causing unintended problems. For example, software allow lists can be negatively impacted by software patching. If allow lists are based on executable file hash values, they will fail to recognize newly patched executables after patching because their hash values will change. This can result in fully patched systems that are unusable by employees because none of the previously allowed software can run. Regarding change management, it is important to incorporate the potential impacts of allow and block lists into the testing plan.



Software Restriction Policies (block list) can be based on file hash values. (Screenshot used with permission from Microsoft.)

Restricted activities refer to actions or changes that require additional scrutiny, strict controls, or higher levels of approval/authorization due to their potential impact on critical systems, sensitive data, or regulatory compliance.

Restarts, Dependencies, and Downtime

Service and application restarts, as well as downtime, are critical considerations because they typically have a direct impact on business operations. For example, reconfigurations and patching changes often require restarting services or applications, leading to downtime. One of the primary goals of change management is to minimize these disruptions by scheduling restarts or downtime events during maintenance windows or off-peak times to reduce the impact on users and business processes.

Change management processes include communication requirements designed to ensure relevant stakeholders are aware of service outages so they can prepare accordingly. Effective change communication enhances the visibility of the change management process among stakeholders and fosters a culture of transparency and cooperation.

Services and applications often depend on other software, interfaces, and services to function correctly. These dependencies complicate changes because a service restart in one area may significantly impact another. For example, if a database server is restarted, all applications that rely (depend) on the database will likely experience issues or downtime. A change that initially appeared to be minor may impact a wide range of the organization's operations. A careful analysis of software and system dependencies is critical for reasons like these. Understanding what services depend on each other, how restarts impact them, and what measures need to be taken to mitigate potential impacts help avoid unintended outages.

Dependencies also impact the time needed for a change. If a service restart requires other services to be shut down or restarted, the overall change process will need more time. Additionally, backout plans may also need to consider dependencies as part of the process, which will also require additional time.

Understanding the risks associated with restarts and downtime drives the development of effective backout plans and downtime contingencies, ensuring the organization is well-prepared to handle any potential complications and unintended consequences related to the change. Additionally, understanding risks associated with a change also supports the development of post-change performance monitoring to validate that systems function as required and help detect issues quickly. Sometimes, the potential risks of a change causing significant disruption require the organization to identify alternative solutions.

Some typical IT changes that generally require service or application restarts and result in downtime are as follows:

Change Type	Description
Software upgrades and patches	When upgrading software applications, especially major version updates or patches, a restart of the application is typically needed to apply the changes effectively and ensure the updated version is fully functional.
Configuration changes	Many system configuration changes, such as modifying server settings, network configurations, or database parameters, require a restart of the affected services to apply the changed configurations properly.
Infrastructure changes	When changing infrastructure components, such as switches, routers, firewalls, and load balancers, it is typically necessary to restart the devices to apply the changes and ensure they do not negatively impact operation.
Security changes	Implementing specific security measures, such as updating encryption protocols, enabling or disabling security features, or modifying access control settings, may require a restart of the services or applications to enforce the new security configurations effectively.

Downtime refers to the scheduled time designated for changes to be implemented (scheduled downtime) or the amount of time a service or application is unavailable (unscheduled downtime).

Legacy Systems and Applications

Legacy applications pose unique challenges regarding change management as these systems are often critical to business operations and are difficult to manage. Many legacy applications are built using outdated technology, which introduces compatibility issues when implementing changes. For example, new software or security updates may be incompatible with legacy systems. These Incompatibility issues might require specialized solutions, such as virtualization, emulation, interpreters, custom "fit-gap" software, or modifications to the newer components to ensure compatibility. These accommodations further complicate the manageability of the legacy application.

Legacy applications often lack comprehensive documentation or have been heavily customized over years or even decades, making them extremely difficult to manage. This complexity necessitates extensive testing and meticulous implementation plans to help avoid unintended consequences or outages. Legacy applications also typically lack vendor support, removing the option to "call for help," which increases the risks associated with any change. A lack of vendor support coupled with high complexity, poor documentation, and business criticality make legacy systems a significant security problem.

Documentation and Version Control

Version control refers to tracking and controlling changes to documents, code, or other important data. Organizations can use version control to maintain a historical record of changes, ensure only approved changes are implemented, and quickly revert changes to a previous version as warranted. Version control is also important when diagrams, policies, and procedures require updates. In this way, version control prevents confusion associated with using outdated or inconsistent documents.

Assessing how a change impacts existing policies, procedures, and diagrams is essential, and change management plans should include provisions requiring updates to these documents as part of the implementation. The frequency of diagram and documentation updates varies, but they are typically updated whenever significant changes or modifications to a process, system, or application occur. Once document updates have been completed, the new versions should be clearly labeled, and the older versions should be archived but still available for reference. Major changes may necessitate training for relevant teams or departments.

Change management is a crucial aspect of implementing changes to a system or application. By assessing the potential technical implications of these changes, organizations can take necessary steps to minimize disruptions. Effective change management requires following specific processes, such as developing implementation plans and conducting thorough testing procedures. Through change management, leadership can ensure that any changes made are successful and contribute positively to the organization.

Some examples of different documentation impacted by change management include the following:

Item	Description
Change requests	Change requests themselves should be reviewed and updated to reflect the details and status of the change, including any modifications or approvals during the change management process.
Policies and procedures	Changes may impact existing policies and procedures. As a result, these documents need to be reviewed and updated to ensure they align with the new processes, guidelines, or controls introduced through the change.
System or process documentation	Documentation should reflect any changes to systems, applications, or processes. It may involve updating system architecture, diagrams, process flows, standard operating procedures (SOPs), or user manuals to represent the current state and functionality of the changed system.
Configuration management documentation	Changes to configuration items, such as servers, networks, or databases, should be tracked and documented within the configuration management system to maintain an accurate record of its configuration.
Training materials	Changes often impact employees, and they may require more training. Existing training materials, such as presentations, manuals, or computer-based learning modules, must be reviewed and updated as warranted.
Incident response and recovery plans	Changes made to systems or applications may necessitate updates to incident response and recovery plans to ensure they account for the revised configurations, new dependencies, or recovery procedures resulting from the change.

Policies and procedures must change as often as technology does, which is often!

11.2.3 Practice Questions (Section Quiz)

q_change_management_allow_list_secp8

A recently breached company tasks the cyber team to further restrict end-user permissions.

What describes the use of an application allow list?

Answers:

***It enforces policies in computer systems and networks.**

It is used in computer systems and networks to enforce policies.

It is a list of rules or entries that specify users' access.

It controls access to files, directories, or systems resources in OSs.

Explanation:

An allow list (or approved list) will deny an execution unless it is a process that the organization explicitly authorizes.

Organizations can use access control lists (ACLs) in computer systems and networks to enforce access control policies.

An ACL is a list of rules or entries that specify a user or a group's access to specific resources or ability to perform certain actions.

ACLs control access to operating and file systems' files, directories, or system resources. Each access control entry (ACE) typically contains a user or group identifier and the associated permissions that allow or deny actions.

q_change_management_app_changes_secp8

At a medium-scale software development firm, significant modifications to several critical applications employees use daily are on the horizon.

Considering the principles of change management, what should the primary focus be during the implementation phase of these changes?

Answers:

***Scheduling service restarts during non-business hours to minimize application downtime.**

Ensuring high-risk alterations are prioritized and subject to the entire change management process.

Updating the block list to encompass previous versions of the applications.

Concentrating solely on the allow list while disregarding the block list for a smoother transition.

Explanation:

One of the main objectives of change management is to minimize disruptions to business operations. The company can achieve this by scheduling service restarts during off-peak hours or maintenance windows.

While high-risk alterations should indeed be subject to the entire change management process, this should not be the primary focus during the implementation phase of the changes.

While including previous versions of applications in the block list could be a part of change management, it should not be the primary focus while implementing the changes.

Solely concentrating on the allow list while disregarding the block list would not be advisable. Both lists play crucial roles in the change management process and implementation.

q_change_management_backout_plan_secp8

A software patch was inadvertently pushed out early, during the middle of the workday, and has brought business to a halt. The chief executive officer (CEO) demands that the systems return to full operations immediately.

What part of the change plan will assist in this task?

Answers:

***Backout plan**

Impact analysis

Test results

Standard operating procedures

Explanation:

A backout plan is for reversing changes and returning systems and software to their original state if the implementation plan fails. A well-defined backout plan helps to minimize downtime and reduces the risk of data loss or other severe impacts.

An impact analysis identifies and assesses the potential implications of a proposed change, including how the change will impact all areas.

Evaluation of changes in a test environment ensures they work as intended. Test results provide valuable insight into the likelihood of success without impacting business operations.

Standard operating procedures (SOPs) describe how to carry out routine operations or changes. In change management, SOPs ensure that change implementation is consistent and effective.

q_change_management_change_times_secp8

A properly implemented change plan for an international company helps keep business operations moving forward. Restarts, dependencies, and downtime are hand-in-hand with change management.

When is the BEST time to implement changes? (Select two.)

Answers:

After the work day

***Off-peak times**

Peak times

***Maintenance windows**

During holidays

Explanation:

If an organization needs to perform a change during the day, it should take place during off-peak times, broadcasting the intention to all the users.

Maintenance windows consist of scheduled times when services can safely restart to allow for all changes made per the change management policy.

While after the work day is possibly "off-peak time," many users work past a normal quitting time to focus on critical tasking.

Any changes should avoid peak times when users are at their most active work schedule, and implementing a change would cause the most disruption.

While holidays could be a good time to implement changes, in an international company holidays vary from location to location and its not always easy to find a consistent time to make the changes. In addition, the IT administrators making the changes would need to use holiday time to make the changes.

q_change_management_cmb_secp8

An educational institution plans to transition from a traditional to a digital learning system. The school's administration has assembled a Change Management Board (CMB) to ensure smooth and secure execution.

Within the scope of this educational institution's digital transformation project, what would be the primary role of the CMB?

Answers:

***Assessing, approving, and managing changes in the IT infrastructure**

Conducting cybersecurity awareness training for all school staff

Developing and implementing the school's digital learning curriculum

Overseeing the daily operations of the school's IT department

Explanation:

A CMB in any organization actively evaluates proposed changes, determines their potential impact, decides on their implementation, and manages these changes to minimize disruption and risk.

A security training team or department generally takes responsibility for this important aspect of overall cybersecurity, not the CMB.

Curriculum development and implementation are tasks that academic and educational technology departments actively perform. The CMB becomes involved only when these changes influence the IT infrastructure.

Managing changes to the IT infrastructure is the primary focus of the CMB, not overseeing the day-to-day operations of the IT department. IT managers or department heads usually take on this responsibility.

q_change_management_dependencies_secp8

An organization frequently implements changes, reconfigurations, and patches to enhance its IT infrastructure's security and efficiency. The cybersecurity analyst must carefully analyze dependencies between services, applications, and interfaces to avoid unintended outages and disruptions during service restarts or downtime events.

How does understanding dependencies impact the change management process? (Select the three best options.)

Answers:

***Helps avoid unintended outages and disruptions during service restarts or downtime events.**

***Guides the development of effective backout plans and downtime contingencies.**

***Supports the development of post-change performance monitoring to validate system functionality and quickly detect issues.**

Helps minimize the need for backout plans during changes.

Increases the involvement of stakeholders in the change management process.

Informs individuals or groups that are primarily responsible for implementing a specific change.

Guides the approval process to ensure proper assessment and approval of change proposals.

Explanation:

The following are areas for understanding how dependencies impact the change management process:

By knowing the dependencies, we can avoid unintended outages and disruptions during service restarts or downtime events and ensure that changes do not negatively impact interconnected services or applications.

When we understand the dependencies, we can guide the development of effective backout plans and downtime contingencies, thus preparing the organization to handle potential complications during changes.

By understanding the dependencies, we support the development of post-change performance monitoring to validate system functionality and promptly detect any issues that may arise after the change.

While understanding dependencies is essential for effective change management, it does not necessarily increase understanding in the following areas:

Minimizing the need for backout plans.

The involvement of stakeholders in the change management process.

Individuals or groups that are primarily responsible for implementing a specific change.

The approval process to ensure proper assessment and approval of change proposals.

q_change_management_legacy_apps_secp8

You are the IT manager at a large corporation. The company has been using a legacy application for several years. The application is critical for daily operations but it's not compatible with newer technologies the company plans to adopt.

The vendor no longer supports the application and it has known security vulnerabilities.

What should you do?

Answers:

Continue using the legacy application and hope no security breaches occur.

Immediately stop using the legacy application and switch to the new technology.

***Develop a plan to phase out the legacy application while adopting the new technology.**

Ignore the new technology and focus on finding a new vendor to support the legacy application.

Explanation:

Developing a plan to phase out the legacy application allows the company to address the security vulnerabilities and compatibility issues while minimizing disruption to daily operations is the best option. The plan should include risk assessment, training for users, data migration, and other key considerations.

Continuing to use the legacy application and hope no security breaches occur is not a good option because it leaves the company vulnerable to potential security breaches. Ignoring known vulnerabilities is not a responsible or effective way to manage IT risks.

Immediately stopping use of the legacy application and switch to the new technology could disrupt daily operations and cause significant problems. Switching to a new technology without a transition plan could lead to data loss, downtime, and other issues.

Ignoring the new technology and focusing on finding a new vendor to support the legacy application might seem like a solution but it's not practical or efficient. The legacy application is not compatible with newer technologies, and finding a new vendor to support outdated software could be difficult and costly. It also doesn't address the security vulnerabilities.

q_change_management_ownership_roles_secp8

After receiving the annual audit results from the Inspector General's office, a cyber specialist begins identifying points of contact to implement change management on numerous flagged processes.

Understanding the various positions tied to change management, which roles would normally have ownership in the change management process? (Select two.)

Answers:

***Project manager**

***Team leader**

Vendors

Partners

Human resources

Explanation:

Ownership in change management refers to individuals or groups primarily responsible for implementing a specific change and may also include project managers.

The team leader's role is also considered a big part of the ownership group. Implementing change as planned, managing risk effectively, and a clear plan for communication and training associated with the change are all part of accountability for this leadership role.

The role of a vendor is a stakeholder in the change management process, so there is no direct tie to ownership.

Similarly, the role of a partner is also a stakeholder, so there is no association with ownership responsibilities.

Human resources is not a stakeholder in the change management process, and would have no association with ownership responsibilities.

q_change_management_plan_change_components_secp8

Due to the introduction of security vulnerabilities during a previous change, company leadership wants reassurance that the vulnerabilities will not happen again.

The IT department has made several changes to its change management plan.

What are items the IT department would add to this plan? (Select three.)

Answers:

***Impact analysis**

***Test results**

***Backout plans**

Stakeholders

Rack layout diagram

Cable plan

Balance sheet

Explanation:

The following are items that the IT department would normally add to the plan:

Impact analysis identifies and assesses the potential implications of a proposed change, including how the change will impact all areas.

Evaluation of changes in a test environment ensures they work as intended. Test results provide valuable insight into the likelihood of success without impacting business operations.

A backout plan is for reversing changes and returning systems and software to their original state if the implementation plan fails. A well-defined backout plan helps to minimize downtime and reduces the risk of data loss or other severe impacts.

The following are items that the IT department would not normally add to the plan for this scenario:

Stakeholders are personnel with a vested interest in completing the change, but they are not components of a change management plan that would keep vulnerabilities from appearing.

A rack layout diagram and a cable plan are both networking documents for installing and configuring network hardware and are not directly related to correcting security vulnerabilities.

A balance sheet is a financial statement that reports a company's assets, liabilities, and shareholder equity. It is not directly related to a change management plan.

q_change_management_security_updates_secp8

Several mission-essential applications stopped working the morning after implementing a mandatory security update. As a result, implementing the security updates introduced several instabilities in existing software.

What could have prevented this from occurring?

Answers:

Stakeholders

***Change management**

Dependencies

Request for change

Explanation:

If the organization does not have a proper change management program for security updates, it can introduce new vulnerabilities into the system, disrupt services, or negatively impact its compliance status. It will also create additional work to roll everything back to its previous state.

Stakeholders are part of the change management program, including IT professionals with technical knowledge, business leaders with operational knowledge, and compliance officers with legal expertise.

Services and applications often have dependencies on other software, interfaces, and services to function correctly. If not planned correctly, changing one area can make all other applications have problems. This is another reason for a change management program.

A request for change is part of the change management program, and it would be an aspect of the solution, not the solution itself.

q_change_management_software_update_01_secp8

A financial institution receives a significant software update.

What is the optimal approach to handle this situation in a change management program?

Answers:

***Assess impact, test, get approval, apply update.**

Apply to critical systems first, then the rest.

Apply at next maintenance window without assessment.

Update systems with past vulnerabilities only.

Explanation:

In an effective change management program, it is crucial to assess the impact of the update, test it in a controlled environment, get the necessary approvals, and then apply the update system-wide. This step-by-step approach helps mitigate risks and ensure the update aligns with the organization's business objectives.

While applying the updates to a few critical systems first and then the rest seems cautious, it skips important steps such as assessment, testing, and approval.

Applying the update during the next maintenance window without prior assessment, testing, and approval could introduce unexpected risks.

Applying updates only to systems that have shown past vulnerabilities might leave other systems at risk and ignores the assessment process.

q_change_management_software_update_02_secp8

The organization is implementing a significant software upgrade that necessitates application restarts.

How can the cybersecurity analyst ensure a smooth transition without causing extended downtime?

Answers:

***Schedule the upgrade during nonworking hours to reduce the impact on users.**

Conduct the software upgrade without restarting the applications to avoid interruptions.

Restart all applications simultaneously to complete the upgrade faster.

Implement the upgrade without analyzing software dependencies.

Explanation:

The cybersecurity analyst can help minimize disruptions to users and business processes by scheduling the software upgrade during nonworking hours. This approach aligns with change management's goal to reduce the restart impact on business operations.

Restarting the applications is typically necessary to apply the software upgrade changes effectively.

If all the applications restart simultaneously, it can lead to extended downtime and further complicate the troubleshooting process in case of issues.

Implementing the upgrade without analyzing software dependencies is incorrect since understanding potential impacts and ensuring a successful upgrade is crucial.

q_change_management_sop_01_secp8

An organization has an established change management program that includes standard operating procedures (SOPs). It wants to implement changes consistently and effectively.

What role do SOPs play in the change management process?

Answers:

***SOPs define routine operations or changes and provide detailed instructions for their implementation.**

SOPs help track and communicate the status and outcome of approved changes.

SOPs outline the steps for employees to follow when conducting an impact analysis.

SOPs provide guidelines for developing backout plans for changes.

Explanation:

Essential in change management, SOPs provide detailed instructions for routine operations and changes, ensuring consistency and effectiveness in implementation.

While SOPs may include guidelines for documenting and reporting changes, their primary role is not to track and communicate the status and outcome of approved changes.

SOPs do not cover impact analysis procedures separate from change management programs.

SOPs may guide developing backout plans, but it is not their primary role. Their primary focus is on defining the routine operations or changes and providing instructions for their implementation.

q_change_management_sop_02_secp8

What role do standard operating procedures (SOPs) play in the change management process of an organization's established change management program, which aims to guarantee consistent and effective implementation of changes?

Answers:

***SOPs outline regular operations or modifications and provide specific guidance for their execution.**

SOPs help track and communicate the status and outcome of approved changes.

SOPs outline the steps for employees to follow when conducting an impact analysis.

SOPs provide guidelines for developing backout plans for changes.

Explanation:

Having SOPs is crucial for change management since they offer precise guidelines for regular operations and changes. This guarantees that implementation is consistent and effective.

While SOPs may provide instructions for documenting and reporting changes, their primary purpose is not to monitor and inform about the progress and result of approved changes.

The SOPs do not include specific impact analysis procedures distinct from change management programs.

Even though SOPs may include instructions for creating backout plans, their primary purpose is to define routine operations and changes and provide guidance on implementing them.

q_change_management_stakeholders_secp8

Upon receiving the findings from a recent inspection, a senior technician must identify the various parties needed to implement change management solutions.

Based on those impacted by the change, who are primary stakeholders within the change management spectrum? (Select three.)

Answers:

***Partners**

***Vendors**

***Change Advisory Board (CAB)**

Project manager

Third-party suppliers

Customers

Consultants

Explanation:

Stakeholders in the change management process describe the individuals or groups impacted (or interested) in the change. Based on the scenario, the following are stakeholders within the change management spectrum:

The role of partners.

The vendors tied to the project.

The change advisory board (CAB) is also a stakeholder in the change management process and uses the information provided by the ownership cluster to make informed decisions.

Contrary to being a stakeholder, the following are roles that are not involved within the change management spectrum:

A project manager is part of the ownership cluster for change management and is primarily responsible for implementing specific changes.

Because primary stakeholders are normally within the company, third-party suppliers, customers, and consultants are not usually included as primary stakeholders in a change management solution.

q_change_management_version_control_01_secp8

Change management is not just for implementing software updates or hardware changes.

For example, version control refers to capturing changes made to important documents a company needs.

What are some documents that would utilize version control? (Select three.)

Answers:

***Code**

Faxes

***Diagrams**

***Important data**

Financial records

Transactional documents

Employee timecards

Explanation:

The following are documents that might utilize version control:

Capturing implemented changes in code is important as it will allow for a quick reversion to a known good state of the code if a change causes problems.

Capturing changes within diagrams ensures only the most recent diagrams will be available while archiving the previous documents, but still having them available for reference.

Important data will vary from company to company, but tracking changes will allow references for only the most recent data and avoid confusion.

The following are documents that would not normally fall under change management and version control:

Faxes and employee timecards do not fall under change management as they are one-time communications and do not need tracking or logging.

Financial records are meant to be stable and fixed reflections of financial transactions without changes (except for the occasional correction).

Transactional documents are also one-time communications that should reflect circumstances around a transaction at the time of the event.

q_change_management_version_control_02_secp8

How can a cybersecurity analyst effectively utilize version control to maintain a historical record of changes and ensure security in the organization's IT systems and applications?

Answers:

***Use version control to track changes in network diagrams and configuration files.**

Implement version control only for critical documents and code.

Revert to previous versions of documents without assessing their impact on security.

Use version control solely for policy updates, neglecting changes to code.

Explanation:

The analyst should use version control to track changes in critical documents and code, network diagrams, and configuration files. This comprehensive approach helps maintain a historical record of changes and ensures security across various aspects of the organization's IT infrastructure.

Implementing version control solely for critical documents and code would be insufficient to maintain a comprehensive historical record and secure the IT systems.

Reverting to previous versions of documents without assessing their impact on security may introduce vulnerabilities.

Using version control only for policy updates and neglecting changes to code does not address the importance of tracking all relevant areas.

11.3 Automation and Orchestration

As you study this section, answer the following questions:

What roles do automation and scripting play in IT operations, specifically security management?

How does an orchestrated system function if a threat is detected?

How does automation help employees?

What are five challenges that automation presents to maintaining security systems?

The key terms for this section include:

Term	Definition
Workforce multiplier	A tool or automation that increases employee productivity, enabling them to perform more tasks to the same standard per unit of time.
Reaction times	The elapsed time between an incident occurring and a response being implemented.
Single point of failure	A component or system that would cause a complete interruption of a service if it failed.

Technical debt	Costs accrued by keeping an ineffective system or product in place, rather than replacing it with a better-engineered one.
Standard configurations	In an IaC architecture, the property that an automation or orchestration action always produces the same result, regardless of the component's previous state.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	4.7 Explain the importance of automation and orchestration related to secure operations. Use cases of automation and scripting Ticket creation Enabling/disabling services and access Continuous integration and testing Benefits Efficiency/time saving Enforcing baselines Standard infrastructure configurations Staff retention Reaction time Workforce multiplier Other considerations Complexity Cost Single point of failure Technical debt Ongoing supportability

11.3.1 Automation and Scripting (Lesson Video)

Transcript:

Think about the chores you do every day, like washing your clothes or doing the dishes. You could do these things by hand if you wanted, but it would take longer and probably be less effective than doing them with a machine. The process of having machines assist human labor is called automation, and a similar mindset is used in many kinds of computing. In this lesson, I'm going to cover a variety of facts about automation so you can have a better idea of how this works.

The term Development, Security, and Operations is more commonly referred to as DevSecOps. This is the philosophy in which everyone in an organization is responsible for their system's security. This means that everyone should implement security decisions in the same way that development and operation decisions are made. If everyone in a company becomes better at security, the entire organization benefits, and customers have greater software assurance.
While this might take a while to set up initially, it eventually streamlines the process for everyone and leads to lower costs and development times. During the software development process, engineers constantly check each other's work and test the software for bugs and vulnerabilities. In this way, fewer vulnerabilities make their way into the final product, which means that we end up investing less time and money into fixing things post-release.
In a musical orchestra, there are many different instruments that are brought together to create something wonderful. Members follow what's written on their music sheets and the real-time directions given to them by the conductor. Just like a musical orchestra, workflows can be orchestrated to make them as efficient as possible so that they produce the best results.
A workflow refers to a collection of tasks that are performed in a logical sequence. Orchestration means that you plan these tasks in such a way that they're as efficient as possible.
For example, you can orchestrate different parts of your workflow, including the development, quality assurance, and security. Orchestration often incorporates the use of tools that automatically complete certain tasks in a sequence.
To help with workflow orchestration, many companies are using automated cybersecurity solutions that are able to quickly identify and resolve potential attacks. One of these solutions is Security Orchestration, Automation, and Response, which is known by the acronym SOAR.
SOAR refers to a collection of software programs that allow an organization's security team to collect various inputs they can monitor. The point of SOAR is to replace tasks that are repetitive and done manually with automated workflows. These systems automatically flag security incidents and respond to them in a predetermined way.
This means that these incidents are caught earlier. This also frees up security analysts to spend their time and attention on only the most advanced security threats. For example, using a firewall application, SOAR can automatically detect a brute-force login attack and block the attacker's IP address.
Another orchestration technique we see is known as continuous integration, or CI. When you work on a software development team, you often have multiple people contributing to the same project. The practice of continuous integration means that you automate all integration changes made by these contributors back into a shared mainline.
In general, there's a central repository where all code changes are merged into a single file that's used to test the current build's effectiveness. Under this strategy, developers try to merge their changes back to the main branch as often as possible. The new changes are then automatically tested to make sure they don't break the application when they're integrated. This can greatly streamline the development process because developers don't need to manually discuss the changes they make with the rest of the team. This also cuts down on overhead costs and lets developers focus on the code and not on a complex web of communication.
Continuous delivery is like an extension of continuous integration. It automatically deploys all the changes coders make into a production environment. You have both an automated testing process and an automated release process that you can set to occur at whichever interval you feel is best.
Continuous deployment goes a step further than continuous delivery. Continuous deployment means that any change that goes through all the production pipeline stages is automatically released to customers. There's no human intervention in this process, and only if the change fails one of the tests along the way is it prevented from being pushed out. This has the potential to create an extremely streamlined process and quicker responses to customer feedback.
That's it for this lesson. In this lesson, we first discussed DevSecOps and explained how this philosophy adds security measures to every step of the development process. Next, we discussed workflow orchestration and showed how it can help the development process run more smoothly with all the different elements aligned in the most efficient way. A big part of this is automating whichever elements can possibly be automated.

We also introduced you to some tools to help in your orchestration, including SOARS, which lets the security team automatically collect data to help them identify security threats. And finally, we discussed how continuous integration lets you automate the integration of changes from multiple developers into a central staging area. Lastly, we showed that you can use continuous deployment to ensure changes are automatically deployed to a production environment and pushed out to end users.

11.3.2 Automation and Scripting Facts

Automation and orchestration are powerful tools for managing security operations. Automation uses software to perform repetitive, rule-based tasks, such as monitoring for threats, applying patches, maintaining baselines, or responding to incidents, to improve efficiency and reduce the likelihood of human error. Orchestration enhances automation by coordinating and streamlining the interactions between automated processes and systems. Orchestration supports seamless and integrated workflows, especially in large, complex environments with many different security tools and systems. Automation and orchestration also provide clear audit trails supporting regulatory compliance and incident investigation. While their implementation comes with challenges such as complexity, cost, and the potential for a single point of failure, careful management of these tools can greatly improve an organization's security posture.

This lesson covers the following topics:

- Automation and scripting
- Benefits of automation and orchestration in security operations
- Important considerations
- Benefits of infrastructure management automation

Automation and Scripting

Automation and scripting have emerged as critical tools in modern IT operations, helping organizations streamline processes, enhance security, and improve efficiency. Automation serves as a tool to enhance both security governance and change management. In terms of governance, automation can help enforce security policies more consistently and efficiently, and it can aid in monitoring and reporting to provide valuable insights for leadership teams and risk managers. In change management, automation can reduce the risk of human error, reduce implementation time, and provide clear audit trails. For example, scripts are effective for applying patches and updates across an organization's systems uniformly, and automation tools can track these changes for later review.

Benefits of Automation and Orchestration in Security Operations

Automation and orchestration also offer many important benefits to security operations. Primarily, they enhance efficiency by enabling repetitive tasks to be performed quickly and consistently, reducing the burden on security teams and minimizing the likelihood of human error (sometimes referred to as a workforce multiplier).

Operator fatigue refers to the mental exhaustion experienced by cybersecurity professionals due to their work's continuous, high-intensity nature. Security analysts must monitor numerous systems for potential threats, manage high volumes of alerts (including many false positives,) and respond to confirmed threats as quickly as possible. These working conditions often lead to long hours, anxiety, and elevated stress levels, resulting in operator fatigue. This fatigue is a significant concern in cybersecurity because it can lead to decreased alertness and cognitive function and impair the ability of security personnel to identify and respond to threats effectively. Fatigue results in missed critical alerts, slower response times, and a greater likelihood of errors, any of which can compromise security.

Automation and orchestration play crucial roles in combating operator fatigue in security operations by minimizing the repetitive, manual tasks that often contribute to operator fatigue. Automation and orchestration significantly reduce a security team's

workload by automating routine tasks, such as scanning for vulnerabilities, applying patches, or monitoring systems for anomalous activities. This allows for the more efficient use of resources and frees security personnel to focus on more complex, strategic issues that require human judgment and creativity rather than repetitive tasks. Orchestration enhances the impact of automation by coordinating automated tasks across different systems and software tools and reduces detection and reaction times .

For example, if a threat is detected, an orchestrated system can automatically isolate the affected subnet, perform basic analysis and reporting, notify security teams, generate tickets, and document the incident, all without human intervention. Other benefits of automation include enforcing standardized baselines through configuration management tools to override unauthorized changes made to endpoints automatically. A standard baseline in configuration management is a well-defined set of approved configurations and settings that serve as a reference point for establishing and maintaining the desired state of a system. Automation and orchestration can significantly alleviate operator fatigue by reducing the volume of manual, routine tasks and improving the efficiency of security operations, leading to greater job satisfaction, increased alertness and effectiveness in threat detection and response, and, ultimately, more robust security operations.

Automation can support staff retention initiatives by reducing fatigue from repetitive tasks. Automation practices can free staff to perform more rewarding work and increase job satisfaction.

Important Considerations

While automation and orchestration provide numerous benefits, they also present some significant challenges, some of which are listed below:

Complexity — Implementing automation and orchestration requires a deep understanding of an organization's systems, processes, and interdependencies. A poorly planned or executed automation strategy can add complexity, making systems more difficult to manage and maintain.

Cost — The initial cost of implementing automation and orchestration can be high, including costs associated with acquiring and developing appropriate tools, integrating them into existing systems, and training staff to use them effectively. Automation software maintenance and upgrades can also be costly.

Single Point of Failure — If a critical automated system or process fails, it could impact multiple areas of the organization, causing widespread problems.

Technical Debt — Organizations can accrue technical debt if automation and orchestration tools are implemented hastily, resulting in poorly documented code, "brittle" system integrations, or poor maintenance. Over time, this debt can lead to system instability, complexity, and increased costs, ironically similar to the problems associated mainly with legacy systems.

Ongoing Support — Automation and orchestration systems require ongoing support to stay effective and secure, including updates and patches, reviewing and improving automated processes, and continuous education. Without adequate support, the benefits of automation and orchestration are quickly eroded.

Maintaining system security when new hardware or infrastructure items are added to the network can be achieved by enforcing standard configurations across the company. With automated configurations, these newly added items can be kept up-to-date and secure.

Benefits of Infrastructure Management Automation

Automating and orchestrating infrastructure configurations introduces numerous benefits. Enforcing standardized configurations ensures consistency and accuracy throughout the infrastructure. Automation saves time and resources by allowing configurations to be quickly deployed, and it also enhances scalability and flexibility by simplifying the deployment and configuration of new resources.

Furthermore, automation and orchestration improve standardization, compliance, and change management by enforcing predefined configuration standards, making auditing and change tracking easier, and controlling configuration drift. Additionally, automation can strengthen security and governance by enforcing security controls, applying patches consistently, and automating security-related tasks.

11.3.3 Practice Questions (Section Quiz)

q_auto_scripting_automation_challenges_secp8

A tech director evaluates the benefits of implementing automation and orchestration into the organization after receiving approval and funding notification for the annual budget.

Knowing several benefits tied to automation, what challenges exist when managing automation? (Select three.)

Answers:

***Technical debt**

***Single point of failure**

***Cost**

Staff retention

Risk of human error

Implementation time

Applying patches and updates

Explanation:

The following are automation challenges:

One challenge is that organizations can accrue technical debt if the implementation of automation and orchestration tools begins in haste, resulting in poorly documented code, "brittle" system integrations, or poor maintenance.

A challenge can include challenges associated with single points of failure, such as a critical automated system or process failure, impacting multiple areas of the organization and causing widespread problems.

A challenge can involve funding, recognizing that the initial cost of implementing automation and orchestration can be high, including costs associated with acquiring and developing appropriate tools and integrating them into existing systems.

The following are not normally associated with automation challenges:

While important to an organization, they do not consider staff retention a challenge to automation but rather a tool to reduce employee/operator fatigue.

Benefits of using automation include reducing the risk of human error, reducing implementation time, and is effective for applying patches and updates.

q_auto_scripting_automation_orchestration_benefit_01_secp8

As a Security Operations Center (SOC) analyst for a large financial institution that deals with high volumes of alerts and potential threats, what crucial benefit does implementing automation and orchestration in security operations provide?

Answers:

Automation and orchestration simplify the nature of threats and reduce the volume of alerts.

***Automation and orchestration enable repetitive tasks to be performed quickly and consistently, minimizing human error.**

Automation and orchestration eliminate the need for human intervention in security operations.

Automation and orchestration help to cut costs by reducing the number of cybersecurity professionals needed.

Explanation:

Automation improves efficiency in security operations by quickly and consistently performing repetitive tasks, which reduces the incidence of human error often associated with such tasks.

Automation and orchestration do not simplify the nature of threats nor reduce the volume of alerts. They provide tools to handle them more efficiently and reduce manual workload.

Human intervention remains a key part of security operations. Automation and orchestration merely augment human roles, freeing the team to focus on complex issues requiring human judgment.

While automation can reduce some workloads, it does not necessarily decrease the need for cybersecurity professionals. Expert human judgment is essential for streamlining and verifying automated systems.

q_auto_scripting_automation_orchestration_benefit_02_secp8

A technical consultant reviews available automation and orchestration options for security operations after realizing employees' actions place the network architecture at risk.

What are the benefits associated with automation and orchestration implementation? (Select three.)

Answers:

***It enhances efficiency by enabling repetitive tasks to perform with mitigation of risk to human error consistently.**

***It coordinates automated tasks across different systems and software tools for quicker response.**

***It assists staff members from experiencing fatigue and enhances opportunities for retention.**

It assists in funding needed orchestration and automation at a higher price point.

It requires a deep understanding of an organization's systems, processes, and interdependencies.

Ongoing support to stay effective and secure.

A single point of failure for the system.

Explanation:

The following are benefits associated with automation and orchestration implementation:

Automation and orchestration offer many benefits to security operations. They enhance efficiency by enabling users to quickly and consistently perform repetitive tasks, reducing the burden on security teams and minimizing the likelihood of human error.

Orchestration enhances the impact of automation by coordinating automated tasks across different systems and software tools, reducing detection and reaction times.

Automation supports staff retention initiatives by reducing fatigue from repetitive tasks. Automation practices can free staff to perform more rewarding work and increase job satisfaction.

The following are significant challenges when using an automation and orchestration implementation:

Cost is not a benefit but more of a challenge as the initial cost of implementing automation and orchestration can be high, including costs associated with acquiring and developing appropriate tools and training staff to use them effectively.

Implementing automation and orchestration requires a deep understanding of an organization's systems, processes, and interdependencies. A poorly planned or executed automation strategy can add complexity, making systems more difficult to manage and maintain.

Automation and orchestration systems require ongoing support to stay effective and secure, including updates and patches, reviewing and improving automated processes, and continuous education. Without adequate support, the benefits of automation and orchestration are quickly eroded.

A single point of failure means that if a critical automated system or process fails, it could impact multiple areas of the organization, causing widespread problems.

q_auto_scripting_automation_orchestration_challenge_secp8

Upon receiving additional funding for the new quarter, a software team leader looks to acquire new automation and orchestration tools to enhance the IT department.

What is NOT considered a benefit of automation and orchestration implementation for infrastructure management?

Answers:

***Enforcing standardized baselines through configuration management tools**

Enforcing standardized configurations to ensure consistency

Saving time and resources by allowing configurations to deploy quickly

Enhancing scalability and flexibility by simplifying deployment

Explanation:

A benefit of automation in security operations, and not infrastructure management, is to enforce standardized baselines through configuration management tools. It overrides unauthorized endpoint changes automatically.

Automating and orchestrating infrastructure configurations introduces numerous benefits. Enforcing standardized configurations ensures consistency and accuracy throughout the infrastructure.

Automation in infrastructure management saves time and resources by allowing configurations to deploy quickly.

Automation in infrastructure management enhances scalability and flexibility by simplifying the deployment and configuration of new resources. Furthermore, it improves compliance and makes auditing and change tracking easier, which controls configuration drift.

q_auto_scripting_automation_scripting_secp8

A multinational corporation is upgrading its IT infrastructure to enhance security governance and streamline its change management process. The IT department is considering various strategies to accomplish this update.

Which strategy MOST effectively achieves the corporation's goals, considering the inherent risks and benefits?

Answers:

***Implementing automation and scripting to perform tasks quickly and efficiently**

Manual monitoring of security controls and change management protocols

Outsourcing the entire IT operations to a third-party vendor

Using proprietary security solutions without automation

Explanation:

Automation and scripting enhance efficiency and security, which aligns with the corporation's goals. The IT department should use automation and scripting with care to prevent potential risks.

Automation improves monitoring efficiency by making it faster, better, and cheaper than manual monitoring. Manual monitoring does not help the corporation achieve its goal of making its processes more efficient. Instead, it slows down the process, lowers the quality, and increases the cost.

Outsourcing may fail to directly address the corporation's security governance and change management needs. It may also lead to complexities and loss of control.

Proprietary solutions without automation lack efficiency. They do not align with the corporation's objectives for streamlined processes.

q_auto_scripting_automation_tools_secp8

A financial institution is evaluating its incident response plan and wants to incorporate automation to accelerate the detection and mitigation of security breaches.

The security team must ensure that the automation does not inadvertently cause additional issues or conflicts.

What is the BEST approach the team should employ when incorporating automation?

Answers:

Deploying automation scripts without testing or validation.

Utilizing a manual-only approach without integrating any automation tools.

***Integrating automation tools with real-time monitoring and alerting capabilities.**

Outsourcing automation development to a non-specialized third-party vendor.

Explanation:

Integrating automation tools with real-time monitoring and alerting provides timely detection and mitigation of security breaches. This approach aligns with the financial institution's goal of accelerating incident response without compromising security.

Deploying scripts without testing or validation may lead to conflicts or additional issues, failing to meet the institution's requirements for secure automation.

Utilizing a manual-only approach without integrating any automation tools is not an automation solution.

Outsourcing automation development to a non-specialized third-party vendor poses a risk of introducing additional issues and conflicts.

q_auto_scripting_code_branch_secp8

A tech department evaluates the benefits of automation and scripting after recently acquiring new funding.

What capability within automation and scripting allows developers to regularly merge their changes back to the main code branch and evaluate each merge automatically to help detect and fix integration problems?

Answers:

***Continuous integration and testing**

Guardrails

User provisioning

Resource provisioning

Explanation:

The principles of continuous integration and testing hinge heavily on automation. In this approach, developers regularly merge their changes back to the main code branch and evaluate each merge automatically to help detect and even fix integration problems.

Guardrails and security groups are not the optimal answer in this scenario. Instead, they provide frameworks for managing security within an organization.

User provisioning describes creating, modifying, or deleting user accounts and access rights across IT systems.

Resource provisioning describes allocating IT resources such as servers, storage, and networks to applications and users.

q_auto_scripting_complexity_secp8

A technician wants to implement automation within the team's workspace.

How does complexity impact automation and orchestration?

Answers:

***Poorly planned strategies can make systems difficult to maintain.**

It can impact multiple areas of the organization, causing widespread problems.

It can result in poorly documented code, leading to instability and increased costs.

It can quickly erode if they do not continue the needed patches and updates.

Explanation:

While automation and orchestration provide numerous benefits, they can also present numerous challenges. A poorly planned or executed automation strategy can add complexity, making systems difficult to maintain.

Single points of failure can impact multiple areas of the organization, causing widespread problems since no redundancy of operations exists.

When organizations make haste decisions in technology, technical debt can result in poorly documented code or maintenance. Over time, technical debt can lead to system instability and increased costs.

Automation and orchestration require ongoing support to stay effective and secure. Automation and orchestration will quickly erode without support.

q_auto_scripting_infrastructure_management_secp8

Which of the following is a benefit of infrastructure management automation?

Answers:

Increasing the volume of manual, routine tasks

Decreasing the efficiency of security operations

***Reducing the risk of human error**

Increasing operator fatigue

Explanation:

Reducing the risk of human error is a benefit of infrastructure management automation. Automation can help reduce the risk of human error by automating repetitive tasks, such as applying patches and updates across an organization's systems uniformly.

Increasing the volume of manual, routine tasks is not a benefit of infrastructure management automation. In fact, one of the main advantages of automation is that it reduces the volume of manual, routine tasks, allowing staff to focus on more complex, strategic issues.

Decreasing the efficiency of security operations is not a benefit of infrastructure management automation. Automation and orchestration enhance efficiency by enabling repetitive tasks to be performed quickly and consistently, reducing the burden on security teams and minimizing the likelihood of human error.

Increasing operator fatigue is not a benefit of infrastructure management automation. By reducing the volume of manual, routine tasks, automation can significantly alleviate operator fatigue, leading to greater job satisfaction and increased alertness and effectiveness in threat detection and response.

q_auto_scripting_operator_fatigue_secp8

A company has been experiencing issues with operator fatigue within the cybersecurity team, leading to decreased alertness and cognitive function.

Considering different strategies to help combat this issue, how can automation and orchestration assist in addressing operator fatigue in security operations?

Answers:

By reducing the initial cost of implementing security measures.

By enforcing standardized baselines and overriding unauthorized changes.

***By automating routine tasks, allowing cybersecurity personnel to focus on more complex, strategic issues.**

By increasing the complexity of the company's systems and processes.

Explanation:

By automating routine tasks such as scanning for vulnerabilities, applying patches, or monitoring systems, automation and orchestration can significantly reduce a cybersecurity team's workload. This reduces operator fatigue by allowing cybersecurity personnel to focus on more complex, strategic issues.

While automation and orchestration might save costs in the long run due to increased efficiency and reduced errors, the initial cost of implementation can be high.

While enforcing standardized baselines and overriding unauthorized changes is a benefit of automation and orchestration, it does not directly address operator fatigue. This benefit maintains consistent system configurations and security.

Increased complexity is actually a potential challenge of implementing automation and orchestration, not a benefit, and does not address operator fatigue.

q_auto_scripting_security_analysts_secp8

In an IT environment, automation and scripting play a critical role in managing services and access.

How does automation assist security analysts in their daily tasks?

Answers:

By helping in user and resource provisioning.

By improving the efficiency of ticketing platforms.

By facilitating the development of more complex systems such as SOAR platforms.

***By enabling and disabling services, modifying access rights, and maintaining the lifecycle of IT resources.**

Explanation:

Automation and scripting are essential tools for managing services and access within an IT environment. This includes enabling or disabling services, modifying access rights, and maintaining the lifecycle of IT resources, which directly aligns with the tasks of security analysts.

While automation assists in user and resource provisioning, the question specifically asks how automation assists security analysts in managing services and access, not provisioning.

While improving the efficiency of ticketing platforms is a benefit of automation, it does not directly apply to the tasks of security analysts in managing services and access within an IT environment.

While automation does facilitate the development of more complex systems like Security Orchestration Automated Response (SOAR) platforms, this is not a direct way that it assists security analysts in managing services and access.

q_auto_scripting_technical_debt_secp8

A cybersecurity analyst works in an organization with several legacy systems with undocumented code and poorly maintained integrations.

How can the cybersecurity analyst address the technical debt associated with these legacy systems using automation and orchestration?

Answers:

***Utilize automation and orchestration to improve documentation and maintenance of the code and integrations.**

Avoid implementing automation and orchestration to prevent system instability.

Apply automated patches and updates without understanding the systems' complexities.

Ignore technical debt as it poses no immediate security risk.

Explanation:

The cybersecurity analyst can streamline and standardize the documentation process for the legacy system's code and integrations by implementing automation and orchestration. Automated processes can generate comprehensive documentation, making it easier for the analyst and other team members to understand and modify the code when necessary.

Avoiding implementation is incorrect because implementing automation and orchestration focusing on documentation and maintenance can reduce technical debt, leading to better system stability.

Applying automated patches is incorrect because applying automated patches and updates without understanding the systems' complexities may exacerbate technical debt and introduce potential security risks.

Ignoring technical debt can lead to long-term problems, including system instability and increased security risks.

q_auto_scripting_ticketing_advantages_secp8

What advantages can automation and scripting bring to IT operations ticketing platforms?

Answers:

***Support tickets are automatically generated and routed for incidents detected by monitoring systems.**

Security policies are enforced to prevent risky activities and unauthorized behavior.

Services and access are better managed within an IT environment.

Automated testing helps improve code quality and speeds up development cycles.

Explanation:

Automation and scripting can create support tickets for IT incidents, ensuring that the relevant team or individual can promptly resolve them.

In IT operations, automation is a valid means of enforcing security policies to prevent risky activities and unauthorized behavior, although it is not limited to ticketing platforms.

Although not directly tied to ticketing platforms, managing services and access within an IT environment is a valuable application of automation.

Enhancing code quality and expediting development cycles through automatic testing are valuable benefits of automation, but they are not directly associated with ticketing platforms in IT operations.

q_auto_scripting_workforce_multiplier_secp8

A third-party escalation team participates in a newly contracted project with numerous cyber teams. Being unfamiliar with cyberspace, the escalation team struggles to understand concepts and naming conventions.

What is automation and orchestration also known as?

Answers:

***Workforce multiplier**

Guardrail

User provisioning

Resource provisioning

Explanation:

Automation and orchestration, also known as a workforce multiplier, enhances efficiency by quickly and consistently performing on enabling repetitive tasks, reduces the burden on security teams, and minimizes the likelihood of human error.

Guardrails and security groups are not the optimal answer in this scenario, but they provide frameworks for managing security within an organization.

User provisioning describes creating, modifying, or deleting user accounts and access rights across IT systems and is not a reference to automation and orchestration.

Resource provisioning describes allocating IT resources such as servers, storage, and networks to applications and users.

12.0 Risk Management Processes

12.1 Risk Management Processes and Concepts

As you study this section, answer the following questions:

Why are disaster recovery policies important for an organization's security?

What is the difference in acceptance and mitigation in risk management?

What is the difference in qualitative and quantitative risk assessment?

How is the annualized rate of occurrence (ARO) calculated?

What are examples of external risk types?

The key terms for this section include:

Term	Definition
Risk management	The cyclical process of identifying, assessing, analyzing, and responding to risks.
Business impact analysis (BIA)	Systematic activity that identifies organizational risks and determines their effect on ongoing mission-critical operations.
Mission essential function (MEF)	Business or organizational activity that is too critical to be deferred for anything more than a few hours, if at all.
Maximum tolerable downtime (MTD)	The longest period that a process can be inoperable without causing irrevocable business failure.
Recovery time objective (RTO)	The maximum time allowed to restore a system after a failure event.
Work recovery time (WRT)	In disaster recovery, time additional to the RTO of individual systems to perform reintegration and testing of a restored or upgraded system following an event.
Recovery point objective (RPO)	The longest period that an organization can tolerate lost data being unrecoverable.
Mean time between failures (MTBF)	Metric for a device or component that predicts the expected time between failures.

Mean time to repair (MTTR)	Metric representing average time taken for a device or component to be repaired, replaced, or otherwise recover from a failure.
Risk identification	Within overall risk assessment, specific process of listing sources of risk due to threats and vulnerabilities.
Risk mitigation (or remediation)	The response of reducing risk to fit within an organization's willingness to accept risk.
Risk deterrence (or reduction)	In risk mitigation, the response of deploying security controls to reduce the likelihood and/or impact of a threat scenario.
Avoidance	In risk mitigation, the practice of ceasing activity that presents risk.
Risk acceptance	The response of determining that a risk is within the organization's appetite and no countermeasures other than ongoing monitoring is needed.
Risk exception	A category of risk management that uses alternate mitigating controls to control an accepted risk factor.
Risk exemption	A category of risk management that accepts an unmitigated risk factor.
Residual risk	Risk that remains even after controls are put into place.
Likelihood	In risk calculation, the chance of a threat being realized, expressed as a percentage.
Probability	The mathematical measure of the possibility of a risk occurring.
Impact	The severity of the risk if realized by factors such as the scope, value of the asset, or the financial impacts of the event.
Enterprise risk management (ERM)	The comprehensive process of evaluating, measuring, and mitigating the many risks that pervade an organization.
Risk assessment	The process of identifying risks, analyzing them, developing a response strategy for them, and mitigating their future impact.
Risk analysis	Process for qualifying or quantifying the likelihood and impact of a factor.

Quantitative risk analysis	A numerical method that is used to assess the probability and impact of risk and measure the impact.
Single loss expectancy (SLE)	The amount that would be lost in a single occurrence of a particular risk factor.
Annualized loss expectancy (ALE)	The total cost of a risk to an organization on an annual basis. This is determined by multiplying the SLE by the annual rate of occurrence (ARO).
Annualized rate of occurrence (ARO)	In risk calculation, an expression of the probability/likelihood of a risk as the number of times per year a particular loss is expected to occur.
Qualitative risk analysis	The process of determining the probability of occurrence and the impact of identified risks by using logical reasoning when numeric data is not readily available.
Inherent risk	Risk that an event will pose if no controls are put in place to mitigate it.
Risk register	A document highlighting the results of risk assessments in an easily comprehensible format (such as a 'traffic light' grid). Its purpose is for department managers and technicians to understand risks associated with the workflows that they manage.
Heat map risk matrix	A graphical table indicating the likelihood and impact of risk factors identified for a workflow, project, or department for reference by stakeholders.
Key Risk Indicators (KRIs)	The method by which emerging risks are identified and analyzed so that changes can be adopted to proactively avoid issues from occuring.
Risk owner	An individual who is accountable for developing and implementing a risk response strategy for a risk documented in a risk register.
Risk appetite	A strategic assessment of what level of residual risk is tolerable for an organization.
Risk tolerance	Determines the thresholds that separate different levels of risk.
Risk reporting	A periodic summary of relevant information about a project's current risks. It provides a summarized overview of known risks, realized risks, and their impact on the organization.
Continuity of operations (COOP)	Identifies how business processes should deal with both minor and disaster-level disruption by ensuring that there is processing redundancy supporting the workflow.

Capacity planning	A practice which involves estimating the personnel, storage, computer hardware, software, and connection infrastructure resources required over some future period of time.
Hot site	A fully configured alternate processing site that can be brought online either instantly or very quickly after a disaster.
Warm site	An alternate processing location that is dormant or performs noncritical functions under normal conditions, but which can be rapidly converted to a key operations site if needed.
Cold site	A predetermined alternate location where a network can be rebuilt after a disaster.
Geographic dispersion	A resiliency mechanism where processing and data storage resources are replicated between physically distant sites.
Platform diversity	Cybersecurity resilience strategy that increases attack costs by provisioning multiple types of controls, technologies, vendors, and crypto implementations.
Tabletop exercises	A discussion of simulated emergency situations and security incidents.
Simulations	A testing technique that replicates the conditions of a real-world disaster scenario or security incident.
Parallel processing tests	Running primary and backup systems simultaneously to validate the functionality and performance of backup systems without disrupting normal operations.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	3.4 Explain the importance of resilience and recovery in security architecture. High availability Site considerations Hot Cold Warm

12.1.1 Risk Types and Tolerance (Lesson Video)

Transcript:

Risk management is the process of identifying vulnerabilities and threats, and then deciding on countermeasures to reduce the risk to an acceptable level. In other words, risk management is when a person or group considers worst-case scenarios and determines just how bad those scenarios would be for their organization. Senior management is ultimately responsible for residual risk, which is what remains after taking risk-reduction measures.

This all might sound kind of depressing. But it's actually pretty liberating because you can feel secure knowing that you've thought through all possible problems. It's kind of like insurance. No one wants bad stuff to happen, but you invest in an insurance policy so that you can have peace of mind that if something does happen, you'll be ready.
The first step in risk management is to identify your organization's assets and how much each asset is worth. You want to pay special attention to assets that are critical for your business to function. You should place values on all assets, including the cost of lost data, failed systems, downtime, and training new employees.
Assets include physical items like computers and storage devices. These items are usually purchased, and so it's fairly easy to place a value on them. But it becomes a bit harder to place a value on an intangible asset like computer data or a seasoned employee's knowledge. While a computer can be easily replaced, the data itself is possibly far more valuable in the end. It's difficult to assign values to things like that, but it's important to attempt to.
After you've identified your assets, you should then identify possible asset threats, which can be internal or external. Internal threats come from within your organization and could include employee fraud, theft, system failure, sabotage, espionage, collusion, or snooping.
External threats are things like fire, water damage, burglars, internet attacks, market competition, or natural disasters.
Let's talk about risk analysis. Risk analysis is the practice of assessing which risks you've identified to be the most relevant to the organization. This is a key part of the risk management process. Risk assessment determines quantitative and qualitative risk values as they relate to a particular threat. As a best practice, we try to create risk assessments using quantitative measurements, which require us to assign a number value to each identified risk.
You should also evaluate your risks. This means determining if and when action should be taken in a worst-cast scenario. You would use this during the analysis phase to determine each risk's tolerability.
Finally, once all risks have been identified and assessed, their management falls into one of four categories: avoidance, transference, mitigation, and acceptance. Avoidance is the decision to avoid the risk altogether. In other words, you choose not to engage in an activity because the risk is too high.

Transference involves transferring the risk to someone else. Many organizations have opted to outsource their networking, security, and storage solutions. Doing so helps to transfer a bit of the risk to companies that are better prepared for potential threats. As businesses dependence on technology continues to grow, so does their cyber risk. Another way businesses help prepare for a potentially catastrophic loss is to take out cybersecurity insurance. As with most insurance policies, this protects against events that would have a big financial impact should they occur.
Mitigation is also an option. You could reduce a potential threat's risk by deploying security controls or other protections. An administrative control is an actionable procedure that should be followed to reduce risk. A technical control is a device that's used for this very purpose. For example, you could configure system redundancy so that if the original system were to go down, the redundant system could take over and continue providing services. Organizations should perform regular risk-control assessments to ensure that these controls continue to be effective.
Sometimes, organizations opt to accept a risk because the associated cost is acceptable, or the cost to protect the asset is just too high. A risk appetite statement, put simply, is the amount of risk an organization is willing to tolerate in order to reach its objectives. If you do decide to accept a risk, it's important to build response policies around a plausible outcome. Know that in some instances, there might actually be regulations that outline how certain risks must be lawfully handled. In these cases, you want to show that you took all the necessary steps to safeguard against loss. So make sure to study up and consider the guidance of legal counsel.
That's it for this lesson. In summary, the risk management process is the process for identifying threats and deciding which countermeasures to take to reduce an undesirable outcome. Asset and risk identification as well as risk analysis, evaluation, and management strategies all make up the risk management process.

12.1.2 Risk Types and Tolerance Facts

Risk management involves identifying potential issues, assessing their potential impact on the organization, and implementing controls to mitigate them. Key concepts include risk identification, risk assessment, mitigation, and monitoring. Risk appetite and risk tolerance are important in defining how much risk an organization is willing to accept. Methods such as ad hoc, recurring, one-time, or continuous risk assessments help organizations accurately understand their risks. Ultimately, effective risk management helps safeguard the organization's information assets, maintain regulatory compliance, and support strategic objectives.

This lesson covers the following topics:

- Risk Management Processes
- Identification of critical systems
- Mission essential functions
- Risk identification and assessment
- Risk management strategies
- Risk transference
- Risk acceptance

Risk Management Processes

Risk management is a process for identifying, assessing, and mitigating vulnerabilities and threats to the essential functions that a business must perform to serve its customers. You can think of this process as being performed over five phases:

- **Identify Mission Essential Functions** — mitigating risk can involve a large amount of expenditure so it is important to focus efforts. Effective risk management must focus on mission essential functions that could cause the whole business to fail if they are not performed. Part of this process involves identifying critical systems and assets that support these functions.

Identify Vulnerabilities — for each function or workflow (starting with the most critical), analyze systems and assets to discover and list any vulnerabilities or weaknesses to which they may be susceptible.

Identify Threats — for each function or workflow, identify the threat sources and actors that may take advantage of or exploit or accidentally trigger vulnerabilities.

Analyze Business Impacts — the likelihood of a vulnerability being activated as a security incident by a threat and the impact of that incident on critical systems are the factors used to assess risk. There are quantitative and qualitative methods of analyzing impacts and likelihood.

Identify Risk Response — for each risk, identify possible countermeasures and assess the cost of deploying additional security controls. Most risks require some sort of mitigation, but other types of response might be more appropriate for certain types and levels of risks.

Identification of Critical Systems

To support the resiliency of mission essential and primary business functions, it is crucial to perform an identification of critical systems. This means compiling an inventory of business processes and the assets that support them. Asset types include the following:

People (employees, visitors, and suppliers).

Tangible assets (buildings, furniture, equipment and machinery (plant), ICT equipment, electronic data files, and paper documents).

Intangible assets (ideas, commercial reputation, brand, and so on).

Procedures (supply chains, critical procedures, standard operating procedures).

For mission essential functions, it is important to reduce the number of dependencies between components. Dependencies are identified by performing a business process analysis (BPA) for each function. The BPA should identify the following factors:

Inputs — the sources of information for performing the function (including the impact if these are delayed or out of sequence).

Hardware — the particular server or datacenter that performs the processing.

Staff and other resources supporting the function.

Outputs — the data or resources produced by the function.

Process Flow — a step-by-step description of how the function is performed.

Business impact analysis (BIA) is a process that helps businesses understand the potential effects of disruptions on their operations. It involves identifying and assessing the impact of various unplanned threat scenarios on the business, such as accidents, emergencies, and disasters. By conducting a BIA, businesses can proactively create recovery strategies to minimize the impact of disruptions and ensure operational resilience.

For instance, if a DDoS attack suspends an e-commerce portal for five hours, the business impact analysis will be able to quantify the losses from orders not made and customers moving permanently to other suppliers based on historic data. The likelihood of a DoS attack can be assessed on an annualized basis to determine annualized impact in terms of costs. This informatioin is used to assess whether a security control, such as load balancing or managed DDoS mitigation, is worth the investment.

Mission Essential Functions

A mission essential function (MEF) is one that cannot be deferred. This means that the organization must be able to perform the function as close to continually as possible, and if there is any service disruption, the mission essential functions must be restored first.

Functions that act as support for the business or an MEF, but are not critical in themselves, are referred to as primary business functions (PBF).

Analysis of mission essential functions is generally governed by four main metrics:

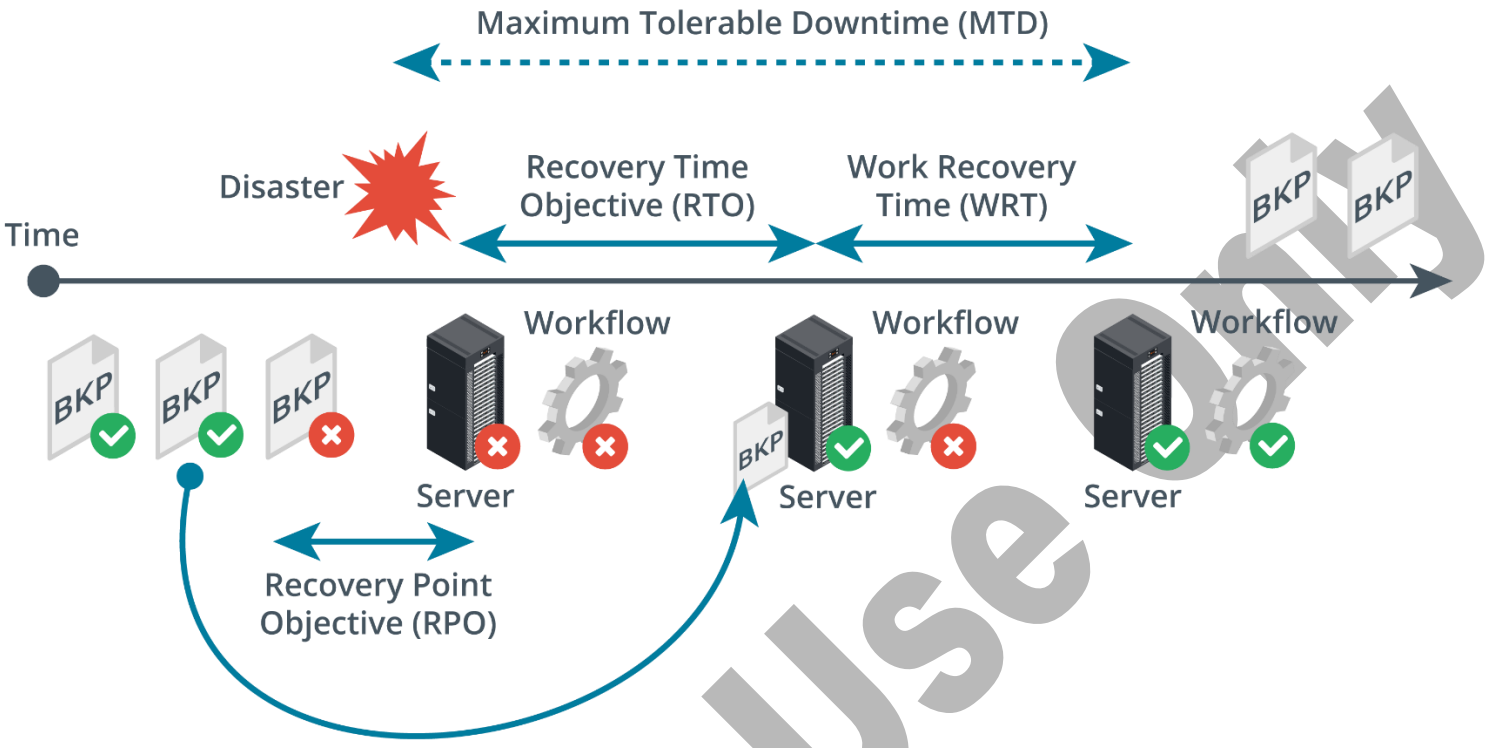
Maximum tolerable downtime (MTD) is the longest period of time that a business function outage may occur for without causing irrecoverable business failure. Each business process can have its own MTD, such as a range of minutes to hours for critical functions, 24 hours for urgent functions, seven days for normal functions, and so on. MTDs vary by company and event. Each function may be supported by multiple systems and assets. The MTD sets the upper limit on the amount of recovery time that system and asset owners have to resume operations. For example, an organization specializing in medical equipment may be able to exist without incoming manufacturing supplies for three months because it has stockpiled a sizable inventory. After three months, the organization will not have sufficient supplies and may not be able to manufacture additional products, therefore leading to failure. In this case, the MTD is three months.

Recovery time objective (RTO) is the period following a disaster that an individual IT system may remain offline. This represents the amount of time it takes to identify that there is a problem and then perform recovery (restore from backup or switch to an alternative system, for instance).

Work Recovery Time (WRT) . Following systems recovery, there may be additional work to reintegrate different systems, test overall functionality, and brief system users on any changes or different working practices so that the business function is again fully supported.

RTO + WRT must not exceed MTD!

Recovery point objective (RPO) is the amount of data loss that a system can sustain, measured in time. That is, if a database is destroyed by a virus, an RPO of 24 hours means that the data can be recovered (from a backup copy) to a point not more than 24 hours before the database was infected. RPO is determined by identifying the maximum acceptable data loss an organization can tolerate in the event of a disaster or system failure and is established by considering factors such as business requirements, data criticality, and regulatory or contractual obligations. The calculation of RPO directly impacts the frequency of data backups, data replication requirements, recovery site selection, and technologies that support failover and high availability.



Metrics governing mission essential functions. (Images © 123RF.com.)

For example, a customer relationship management database might be able to sustain the loss of a few hours' or days' worth of data because employees can generally remember who they have contacted and the conversations they had over this time span. Conversely, order processing is generally more time sensitive, as data losses will represent lost orders, and it may be impossible to recapture them or the related processes initiated by order processing systems, such as accounting and fulfillment data.

MTD and RPO help to determine which business functions are critical and also to specify appropriate risk countermeasures. For example, if your RPO is measured in days, then a simple tape backup system should suffice; if RPO is zero or measured in minutes or seconds, a more expensive server cluster backup and redundancy solution will be required.

Mean time to repair (MTTR) and mean time between failures (MTBF) are key performance indicators (KPIs) used to measure the reliability and efficiency of systems, processes, and equipment. Both metrics are important to risk management processes, providing measurable insights into potential risks and supporting risk mitigation strategies. MTTR and MTBF guide decisions regarding system design, maintenance practices, and redundancy or failover requirements.

Mean time between failures (MTBF) represents the expected lifetime of a product. The calculation for MTBF is the total operational time divided by the number of failures. For example, if you have 10 appliances that run for 50 hours and two of them fail, the MTBF is 250 hours/failure (10*50)/2.

Mean time to repair (MTTR) is a measure of the time taken to correct a fault so that the system is restored to full operation. This can also be described as mean time to replace or recover. MTTR is calculated as the total number of hours of unplanned maintenance divided by the number of failure incidents. This average value can be used to estimate whether a recovery time objective (RTO) is achievable.

A lower MTTR indicates quicker restoration of functionality, reducing downtime and potential disruptions to operations. This information helps allocate resources, prioritize maintenance activities, and optimize repair processes. MTBF identifies the average time between system or equipment failures. A higher MTBF suggests greater reliability and longer intervals between failures,

which can affect maintenance scheduling, spare part management, and overall system performance. Based on MTBF data, organizations can make decisions regarding maintenance strategies, equipment replacement, and investments in improving reliability.

Risk Identification and Assessment

Risk identification is fundamental to managing cybersecurity risks. It includes recognizing risks such as malware attacks, phishing attempts, insider threats, equipment failures, software vulnerabilities, and nontechnical risks like inadequate policies or training. Risk identification methods include vulnerability assessments, penetration testing, security audits, threat intelligence, and other methods. Risk identification is the foundation for risk assessment and management practices. Effective risk identification processes allow organizations to make informed decisions regarding resource allocation, risk mitigation strategies, and overall risk management practices.

Risk Management Strategies

Risk management strategies describe the proactive and systematic approaches used to identify, assess, prioritize, and mitigate risks to minimize their negative impacts.

Risk mitigation (or remediation) is the overall process of reducing exposure to or the effects of risk factors. A countermeasure that reduces exposure to a threat or vulnerability describes risk deterrence (or reduction) . Risk reduction refers to controls that can either make a risk incident less likely or less costly (or perhaps both). For example, if fire is a significant threat, a policy strictly controlling the use of flammable materials on-site reduces likelihood while a system of alarms and sprinklers reduces impact by (hopefully) containing any incident to a small area. Another example is off-site data backup, which provides a remediation option in the event of servers being destroyed by fire.

Avoidance means to stop the activity that is causing risk. For example, a company may develop an internally developed application for managing inventory and then try to sell it. During the sales process, the application may be discovered to have numerous security vulnerabilities that generate complaints and threats of legal action. The company may decide that the cost of maintaining the security of the software is not worth the revenue it generates and its development. Avoidance is infrequently a credible option.

Risk Transference

Transference (or sharing) means assigning risk to a third party, such as an insurance company. Specific cybersecurity insurance or cyber liability coverage protects against fines and liabilities arising from data breaches and attacks.

Note that in this sort of case it is relatively simple to transfer the obvious risks, but risks to the company's reputation remain. If a customer's credit card details are stolen because they used your unsecure e-commerce application, the customer won't care if you or a third party were nominally responsible for security. It is also unlikely that legal liabilities could be completely transferred in this way. For example, insurance terms are likely to require that best practice risk controls have been implemented.

It is not possible to eliminate risks, so a major objective of risk management is to determine an appropriate level of allowable risk. The concept of "allowable risk" varies greatly between organizations and is dependant on industry sector, leadership style, legal environment, and other factors.

Risk Acceptance

Risk acceptance (or tolerance) means that no countermeasures are put in place because the level of risk does not justify it.

A risk exception describes a situation where a risk cannot be mitigated using standard risk management practices or within a specified time frame due to financial, technical, or operational conditions. A risk exception formally recognizes the risk and seeks to identify alternate mitigating controls, if possible. Relevant stakeholders, such as risk managers or senior executives, must

approve all risk exceptions. Risk exceptions should be temporary and reviewed on an established time frame to determine whether the risk levels have changed or if the exception can be removed.

A risk exemption is a condition where risk can remain without mitigation, usually due to a strategic business decision. Risk exemptions are generally associated with situations where the cost of mitigating a risk outweighs its potential harm or can lead to significant strategic benefits when accepted. Similarly to risk exceptions, risk exemptions must be formally documented and approved by risk managers or senior executives and periodically reviewed using an established timetable.

The four risk responses are avoid, accept, mitigate, and transfer.

Where inherent risk is the risk before mitigation, residual risk is the likelihood and impact after specific mitigation, transference, or acceptance measures have been applied. Risk appetite is a strategic assessment of what level of residual risk is tolerable. Risk appetite is broad in scope. Where risk acceptance has the scope of a single system, risk appetite has a project- or institution-wide scope. Risk appetite is constrained by regulation and compliance.

12.1.3 Analyzing Risks (Lesson Video)

Transcript:

In this lesson, we're going to discuss risk analysis. Risk analysis is the practice of determining which identified threats are most pressing to an organization and then attaching a potential cost that can be expected if that threat occurs.

There are two general methods for analyzing and calculating risk. Quantitative analysis assigns real numbers to the costs of damages and countermeasures. It also assigns concrete probability percentages to risk occurrence. Qualitative analysis uses scenarios to identify risks and responses. Qualitative analysis is the more subjective of the two.
When calculating quantitatively, you want to consider a risk's impact and likelihood. What kind of damage can be done, and what's the chance of it actually happening? To determine the likelihood of a loss, you might want to use an annualized rate of occurrence, or ARO. An ARO is a collection of data gathered from historical records such as crime statistics, natural disasters, insurance payouts, and cyber incidence records.
To determine a loss's impact, you want to consider all associated costs if an unfortunate scenario were to occur. What would it cost to pay employees during the downtime? What would it cost to replace the impacted hardware or software? Would there be refunds or other costs associated with user retention?
Single loss expectancy, or SLE, is the amount of loss expected for any single successful asset attack. This is a monetary value that describes how much the incident will cost in terms of lost asset value.
Annual loss expectancy, or ALE, estimates the annual loss resulting from an incident. You calculate ALE by multiplying your SLE by your ARO. This tells you how much potential threats cost each year.
For example, if your asset loses $1,000 for each incident, and you expect an incident every four years, the annual cost for that asset would be $250.00.
Having a visual representation of risks can help stakeholders make better assessments. A risk register provides details of each known risk, including a risk's category, description, unique identification number, projected impact, likelihood of occurrence, and risk response plan. For better visualization, you could use this information to create a scatter plot that represents each risk's possible impact in relation to its overall probability.
A risk matrix, which is also known as a heat map, illustrates a loss's likelihood and impact. Notice that the colors in this example range from cool to hot. If an occurrence's possibility is rare and its impact moderate, it gets a low rating. If its likelihood is high, but the impact is insignificant, it might end up with a medium rating. And if the impact is severe and the likelihood almost certain, it might receive an extreme rating.
That's it for this lesson. In this lesson, we discussed risk analysis. We looked at calculating risks quantitatively and qualitatively, and we discussed a few ways to illustrate our findings.

12.1.4 Analyzing Risks Facts

Effective risk management practices involve systematically identifying, assessing, mitigating, and monitoring organizational risks. Audits provide an independent and objective evaluation of processes, controls, and compliance, ensuring adherence to standards and identifying gaps that pose risks. On the other hand, assessments help evaluate the effectiveness of risk management strategies, identify potential vulnerabilities, and prioritize mitigation efforts. By combining audits and assessments, organizations can comprehensively understand risks, implement appropriate controls, and continuously monitor and adapt their risk management strategies to protect against potential threats. These practices are essential for maintaining proactive and resilient security operations while ensuring compliance with legal mandates.

This lesson covers the following topics:

- Risk management processes
- Risk assessment
- Risk registers
- Risk threshold
- Key risk indicators
- Levels of risk appetite

Risk reporting

Risk Management Processes

For each business process and each threat, you must assess the degree of risk that exists. Calculating risk is complex, but the two main variables are likelihood and impact:

Likelihood is often used in qualitative analysis to describe the chance of a risk event happening subjectively. Likelihood is typically expressed using "low," "medium," and "high" or scored on a scale from 1 to 5.

Probability is a quantitative measure typically expressed as a numerical value between 0 and 1 or a percentage. Probability aims to precisely measure the chance of a risk event occurring based on statistical methods.

Impact is the severity of the risk if realized as a security incident. This may be determined by factors such as the value of the asset or the cost of disruption if the asset is compromised.

Risk management is complex and treated very differently in companies and institutions of different sizes and with different regulatory and compliance requirements. Most companies will institute enterprise risk management (ERM) policies and procedures based on frameworks such as NIST's Risk Management Framework (RMF) or ISO 31K. These legislative and framework compliance requirements are often formalized as a Risk and Control Self-Assessment (RCSA). An organization may also contract an external party to lead the process, referred to as a Risk and Control Assessment (RCA).

An RCSA is an internal process undertaken by stakeholders to identify risks and the effectiveness with which controls mitigate those risks. RCSAs are often performed through questionnaires and workshops with department managers. The outcome of an RCSA is a report. Up-to-date RCSA reports are critical to the external audit process.

Risk Assessment

Risk assessment is a core component of a cybersecurity program that evaluates previously identified risks to determine their potential impact on the organization. Risk assessment methodologies include ad hoc, recurring, one-time, or continuous:

Ad hoc risk assessments are conducted as needed, often in response to specific incidents, such as news of a new, actively exploited zero-day vulnerability or environmental changes such as system upgrades.

Recurring risk assessments are scheduled at regular intervals, such as annually, quarterly, or monthly, and can include audits, compliance checks, vulnerability scans, and other types of assessments.

One-time assessments are comprehensive evaluations carried out at a particular point in time, often during the implementation of a new system (or process) or to obtain an independent assessment of an organization's operational maturity.

Continuous risk assessments constantly evaluate risks and are supported by specialized tools that produce real-time data, such as agent-based vulnerability scanning platforms and intrusion detection systems. Different risk assessment methods are commonly combined to ensure effective identification and management of risk.

Quantitative risk assessment aims to assign concrete values to each risk factor. (Image © 123RF.com.)

Risk analysis describes the process of identifying and evaluating potential risks and the characteristics that define them. Risk analysis aims to understand the nature and scope of risks by examining their causes, consequences, and concerns.

Risk assessment is a systematic approach designed to estimate potential risk levels and their significance by interpreting data collected during risk analysis. Risk assessment considers the likelihood of an event occurring and the severity of its consequences. It may also involve prioritizing risks based on their potential impact and defining risk management strategies.

Quantitative Analysis

Quantitative risk analysis aims to assign concrete values to each risk factor.

Single Loss Expectancy (SLE) — The amount that would be lost in a single occurrence of the risk factor. This is determined by multiplying the value of the asset by an exposure factor (EF). EF is the percentage of the asset value that would be lost. For example, it may be determined that a tornado weather event will damage 40% of a building. The exposure factor in this case is 40% because only part of the asset is lost. If the building is worth $200,000, this event SLE is 200,000*0.4 or $80,000.

Annualized Loss Expectancy (ALE) — The amount that would be lost over the course of a year. This is determined by multiplying the SLE by the annualized rate of occurrence (ARO) . ARO describes the number of times in a year that an event occurs. In our previous (highly simplified) example, if it is anticipated that a tornado weather event will cause an impact twice per year, then the ARO is considered to be simply "2." The ARO is the cost of the event (SLE) multiplied by the number of times in a year it occurs. In the tornado example, SLE is $80,000, and ARO is 2, so the ALE is $160,000. This number is useful when considering different ways to protect the building from tornados. If it is known that tornados will have a $160,000 per year average cost, then this number can be used as a comparison when considering the cost of various protections.

It is important to realize that the value of an asset does not refer solely to its material value. The two principal additional considerations are direct costs associated with the asset being compromised (downtime) and consequent costs to intangible assets, such as the company's reputation. For example, a server may have a material cost of a few hundred dollars. If the server

were stolen, the costs incurred from being unable to do business until it can be recovered or replaced could run to thousands of dollars. In addition, the period of interruption during which orders cannot be taken or go unfulfilled may lead customers to seek alternative suppliers, potentially resulting in the loss of thousands of sales and goodwill.

The value of quantitative analysis is its ability to develop tangible numbers that reflect real money. Quantitative analysis helps to justify the costs of various controls. When analysts can associate cost savings with a control, it is easy to justify its expense. For example, it is easy to justify the money spent on a load balancer to eliminate losses from website downtime that exceeded the cost of the load balancer. Unfortunately, such direct and clear associations are uncommon!

The problem with quantitative risk assessment is that the process of determining and assigning these values is complex and time-consuming. The accuracy of the values assigned is also difficult to determine without historical data (often, it has to be based on subjective guesswork). However, over time and with experience, this approach can yield a detailed and sophisticated description of assets and risks and provide a sound basis for justifying and prioritizing security expenditure.

Qualitative Analysis

Qualitative risk analysis is a method used in risk management to assess risks based on subjective judgment and qualitative factors rather than precise numerical data. Qualitative risk analysis aims to provide a qualitative understanding of risks, their potential impact, and the likelihood of their occurrence. Often referred to as risk analysis using words, not numbers, this approach helps identify and prioritize intangible risks.

One of the benefits of qualitative risk analysis is its simplicity and ease of use. It does not require complex mathematical calculations or extensive data collection, making it a more accessible approach. It allows for a quick initial assessment of risks, enabling organizations to identify and focus on the most significant issues. Qualitative risk analysis frames risks by considering their causes, consequences, and potential interdependencies to improve risk communication and decision-making.

Qualitative risk analysis has some limitations. It is subjective in nature and heavily relies on expert judgment, which often introduces biases and inconsistencies if expert opinions differ. The lack of numerical data in qualitative risk analysis may make communicating risks to stakeholders who prefer quantitative information challenging. Despite these limitations, qualitative risk analysis is important because it provides a simplified description of risks and can help quickly draw attention to significant issues.

Inherent Risk

The result of a quantitative or qualitative analysis is a measure of inherent risk. Inherent risk is the level of risk before any type of mitigation has been attempted.

In theory, security controls or countermeasures could be introduced to address every risk factor. The difficulty is that security controls can be expensive, so it is important to balance the cost of the control with the cost associated with the risk. It is not possible to eliminate risk; rather, the aim is to mitigate risk factors to the point where the organization is exposed only to a level of risk it can tolerate. The overall status of risk management is referred to as risk posture. Risk posture shows which risk response options can be identified and prioritized. For example, an organization might identify the following priorities:

- Regulatory requirements to deploy security controls and make demonstrable efforts to reduce risk. Examples of legislation and regulations that mandate risk controls include SOX, HIPAA, Gramm-Leach-Bliley, the Homeland Security Act, PCI DSS regulations, and various personal data protection measures.
- High-value asset, regardless of the likelihood of the threat(s).
- Threats with high likelihood (that is, high ARO).
- Procedures, equipment, or software that increase the likelihood of threats (for example, legacy applications, lack of user training, old software versions, unpatched software, running unnecessary services, not having auditing procedures in place, and so on).

Heat Map

Another simple approach is the heat map or "traffic light" impact matrix. For each risk, a simple red, yellow, or green indicator can be put into each column to represent the severity of the risk, its likelihood, the cost of controls, and so on. This approach is simplistic but does give an immediate impression of where efforts should be concentrated to improve security.

Risk Factor	Impact	ARO	Cost of Controls	Overall Risk
Legacy Windows Clients				
Untrained Staff				
No Antivirus Software				

Traffic light impact grid.

FIPS 199 (nvlpubs.nist.gov/nistpubs/FIPS/NIST.FIPS.199.pdf) discusses how to apply security categorizations (SC) to information systems based on the impact that a breach of confidentiality, integrity, or availability would have on the organization as a whole. Potential impacts can be classified as the following:

Low — minor damage or loss to an asset or loss of performance (though essential functions remain operational).

Moderate — significant damage or loss to assets or performance.

High — major damage or loss or the inability to perform one or more essential functions.

Risk Registers

A risk register is a document showing the results of risk assessments in a comprehensible format. It includes information regarding risks, their severity, the associated owner of the risk, and all identified mitigation strategies. The register may include a heat map risk matrix (shown earlier) with columns for impact and likelihood ratings, date of identification, description, countermeasures, owner/route for escalation, and status.

Risk registers are also commonly depicted as scatterplot graphs, where impact and likelihood are each an axis, and the plot point is associated with a legend that includes more information about the nature of the plotted risk. A risk register should be shared among stakeholders (executives, department managers, and senior technicians) so that they understand the risks associated with the workflows that they manage.

Risk Threshold

Risk threshold defines the limits or levels of acceptable risk an organization is willing to tolerate. The risk threshold represents the boundaries within which risks are considered to be acceptable and manageable. Risk thresholds are based on various factors such as regulatory requirements, organizational objectives, stakeholder expectations, and the organization's risk appetite to help establish clear guidelines for decision-making. Organizations often define different risk thresholds for different types of risks based on their potential impact and criticality.

Key Risk Indicators

Key Risk Indicators (KRIs) are critical predictive indicators organizations use to monitor and predict potential risks. These metrics provide an early indication of increasing risk exposures in different areas of the organization. KRIs assess the potential impact and likelihood of various risks so leadership teams can take proactive steps to manage them effectively.

Using KRIs is closely associated with risk registers and risk management practices because KRIs provide the data needed to assess the likelihood and potential impact of each risk item tracked in a risk register. For example, a KRI may identify an increasing trend in system downtime due to IT operational issues that impact business operations. Risk managers handle this via a risk register and include details like potential impacts (lost productivity, customer dissatisfaction), mitigation steps (increasing IT resources, improving system redundancy), and the person or team responsible for managing these mitigations.

A risk owner refers to the individual responsible for managing a particular risk, including identifying and assessing the risk, implementing measures to mitigate it, monitoring the effectiveness of the measures, and taking corrective actions as warranted. The risk owner has a comprehensive understanding of the risk and its potential impacts and a thorough understanding of the measures needed to manage it. This role is often assigned to leadership team members with the authority to make decisions and the ability to allocate resources for risk mitigation. The risk owner also communicates information about the risk and its status to other stakeholders.

The risk appetite describes the level of risk that an organization is willing to accept. The organization's risk appetite is critical in determining which risks are added to a risk register and how they are prioritized. Risks are compared to the organization's risk appetite when identified and assessed. Risk tolerance describes the specific amount of variance an organization is willing to accept regarding measured risk levels and the established risk appetite. If a risk item's potential impact or likelihood exceeds the organization's risk tolerance, the risk is added to the risk register for appropriate management and monitoring. Risks that exceed the organization's risk tolerance by a large margin are generally prioritized and treated more urgently than other risks. In contrast, if a risk is near or slightly above the tolerance threshold, leadership teams may decide to accept it and monitor it closely.

Levels of Risk Appetite

Level	Description
Expansionary	An organization with an expansionary risk appetite is willing to take on higher levels of risk in the pursuit of high returns or aggressive growth. These organizations typically operate in rapidly evolving markets or industries and must take risks to remain competitive. Expansionary risk appetites are associated with organizations launching new products, entering new markets, or making major corporate acquisitions.
Conservative	An organization with a conservative risk appetite prioritizes risk avoidance. This type of organization takes a cautious approach to risks and prioritizes preserving cash, maintaining a good reputation, or ensuring regulatory compliance over pursuing aggressive growth.
Neutral	An organization with a neutral risk appetite balances expansionary and conservative approaches. It is willing to take on risks if they align with strategic objectives and can be managed effectively.

Risk Reporting

Risk reporting describes the methods used to communicate an organization's risk profile and the effectiveness of its risk management program. Effective risk reporting supports decision-making, highlights concerns, and ensures stakeholders understand the organization's risks. The content of risk reports must be relevant to its intended audience. For example, reports designed for board members must focus on strategic risks and the organization's overall risk appetite. Operational risk reports must include specific details regarding the factors contributing to risk and are appropriate for managers or technical employees.

Risk reports must also clearly convey recommended risk responses, such as accepting, mitigating, transferring, or avoiding the risk.

12.1.5 Business Continuity Planning (Lesson Video)

Transcript:

In this video, we're going to discuss business continuity planning. Natural disasters can cause catastrophic failures or extended disruptions--anything from a lightning strike that fries a few hardware components to an earthquake that destroys the entire building. Business continuity planning is the creation and validation of a plan for recovering and restoring an organization's mission-critical functions after a catastrophic disaster or extended disruption.

One important component of a business continuity plan is a business impact analysis, or BIA. A BIA focuses on the impact that losses will have on the organization. In a BIA, you identify critical functions--the operational functions that are necessary to conduct your business. Then you prioritize those critical business functions, calculate a timeframe for recovering them after a disaster, and estimate the tangible and intangible impact on the organization.

When you're creating this plan, you'll want to consider several parameters. The first is the recovery time objective, or RTO. The RTO states how much down time your organization can tolerate. It's another way of asking how long it'll take to get your system back up and running in the event of a disaster. Some data protection solutions have a very short recovery time and can bring your network back into operation relatively quickly. Others have a long RTO that lasts several days.

The second parameter is the recover point objective, or RPO. The RPO tells you two things. The first is the maximum length of time you can tolerate between backups. How old can restored data be? For example, if you run backups nightly, the maximum age of your data would be 24 hours because there would be a 24-hour window when no backups were taking place. If your organization only backs up data once a week, the maximum age of your data could be seven days. The longer the time between your backups, the older the data will be.

In an extreme example, if you back up once a week on Sunday and have a catastrophic failure on Friday, all the work done for five or six days would be lost. Most organizations can't tolerate that. But if you run your backups once a day, the maximum age becomes 24 hours. That sounds much better than five or six days, right?

The second thing RPO specifies is the number of backups from which to choose. Some disaster recovery solutions provide one backup. Other solutions may have multiple recovery points to select from. This depends on the data protection itself and how you've configured it.

Another thing to consider during your business impact analysis is the mean time to repair. MTTR identifies the average amount of time needed to repair a failed component or to restore operations. If you provide system access to other organizations, your service level agreement may specify how quickly you guarantee a fully functional and accessible system.

Similarly, the mean time between failures, or MTBF, identifies the average lifetime of a system or component--how long before the system wears out from age or use. Components should be replaced about the time the MTBF is reached.

In the event of a tornado, fire, or hurricane, your building will probably be unusable. Implementing site resiliency â€“ having an alternate location where you can pick up business where you left off â€“ could be extremely beneficial to your organization. There are three categories of site resiliency: hot sites, warm sites, and cold sites.

A hot site, or active backup model, is an alternate location that facilitates a fast and full recovery. This is, by far, the most effective backup option. It's also the most costly. In order to be fully operational within minutes, you need to have an alternate location. All servers, devices, cabling, and infrastructure need to be installed and ready to go. Hot sites often have a live connection to your main site with data copied across to the duplicate servers. This is called mirroring. If the active site fails, the hot site is fully operation immediately, with all the current data on the servers. This transition can occur within minutes or hours, so the downtime is minimal.

A warm site is partially configured. You have an alternate location. Some servers, some devices, some cabling, and some infrastructure is installed, but not everything. Data backups are available, but they aren't mirrored. Some recovery from backup tapes, the cloud, or other backup locations may be needed. This transition could occur within hours or days, so the downtime would be noticeable.

A warm site could be shared with another organization to lower its cost. This can be a good idea. Just make sure that the companies are in different areas so a natural disaster can't take them out at the same time.

Finally, there's a cold site. You do have an alternate location, but all equipment would need to be installed, and all data would need to be recovered. Downtime could extend for several weeks or even months.

No matter what type of site you decide to use, be sure to thoroughly document what you have and what you will need at the alternate location in the event of a disaster.
That's it for this lesson. In this video, we discussed business continuity plans, business impact analysis, and site resiliency, including hot, warm, and cold site architecture.

12.1.6 Business Continuity Planning Facts

Business continuity takes a broad approach, considering not only the continuity of critical functions but also the overall resilience and recovery of the entire organization. Business continuity planning includes the assessment of risks, the development of strategies to mitigate those risks, and the creation of plans to maintain or restore business operations in the face of various threats. This may involve addressing supply chain management, employee safety and communication, legal and regulatory compliance, and reputation management. Business continuity aims to ensure the long-term viability of an organization following a disruption, encompassing both immediate response and ongoing recovery efforts.

This lesson covers the following topics:

- Business continuity plan
- Continuity of operations
- Capacity planning
- Site considerations
- Cloud as disaster recovery (DR)
- Diversity and defense in depth
- Testing Resiliency
- Documentation

Business Continuity Plan

A business continuity plan (BCP) identifies appropriate disaster responses that maintain business operations during reduced or restricted infrastructure and resource capabilities. Also, a BCP identifies actions required to restore the business to normal operation. A business continuity plan is designed to ensure that critical business functions (CBF) can be performed when operations are disrupted.

A good plan documents all important decisions before the disaster strikes. When a disaster occurs, staff members simply need to follow the documented procedures. The process would be similar to the following:

- Identify the disaster, ensure the safety of personnel, and begin to implement recovery procedures.
- Implement short-term recovery mechanisms to bring mission-critical systems online.
- Stabilize operations by restoring supporting departments and functions.
- Implement measures to restore all functions to normal. Switch back from temporary measures to normal operating procedures. The order of restoration is defined in the BCP and then carried out in this last phase. A typical restoration order begins with the systems, databases, and applications that are most critical to the continued operation of the business. The order of restoration often varies significantly from one company to another.

Additional content in the BCP should include:

- Define processes for implementing, testing, and training team members. Team members should be representatives from all major parts of the corporation.
- After the plan has been created, conduct regular practices and training exercises to test portions of the plan. Revise the plan or training as necessary.
- As a BCP or DRP plan evolves, it is essential to collect and destroy all outdated copies of the plan as a new version of the plan is rolled out.
- Assign responsibility for ongoing maintenance of the BCP and DRP plans.

Succession planning is a process for identifying and developing internal people with the potential to fill future key positions within an organization. Succession planning:

- Increases the availability of experienced and capable employees that are prepared to assume specific roles as they become available.
- Ensures that the right competencies are recruited into the organization to be nurtured and developed over time to guarantee smooth transitions for future vacancies.
- Contrasts replacement planning, which focuses on identifying specific backup candidates for given positions.

Continuity of Operations

Continuity of operations (COOP) refers to the process of ensuring that an organization can maintain or quickly resume its critical functions in the event of a disruption, disaster, or crisis. COOP concepts and strategies aim to minimize downtime, protect essential resources, and maintain business resilience. Key elements of a COOP plan include identifying critical business functions, establishing priorities, and determining the resources needed to support these functions. Strategies often involve creating redundancy for IT systems and data, such as implementing off-site backups, failover systems, and disaster recovery solutions. Additionally, organizations may consider alternative work arrangements, such as remote work or co-location arrangements, to maintain operations during a crisis. Developing clear communication and decision-making protocols ensures that employees understand their roles and responsibilities during an emergency.

Regular testing and updating of continuity of operations plans (COOP) are crucial to ensure the organization can maintain essential functions during and after disruptive events. Realistic scenarios designed to simulate various disruptions, such as natural disasters, cyberattacks, or pandemics, must be used to assess the plan's effectiveness. Testing methods often include tabletop exercises, isolated functional tests, or full-scale drills. Each approach provides different levels of assurance and must therefore use pre-established evaluation criteria for measuring performance. In essence, COOP strategies focus on proactively preparing for disruptions, ensuring that organizations can continue to deliver essential services and minimize the impact of unforeseen events on their operations.

Backups

Backups play a critical role in the continuity of operations plans (COOP) by safeguarding against data loss and restoring systems and data in the event of disruptions. Regular testing verifies the integrity and effectiveness of backups. Testing backups helps ensure the backup process functions correctly by simulating various scenarios and allows organizations to identify any issues or gaps in the backup and recovery process. Testing backups validates the recoverability of critical systems and data, reducing the risk of data loss and minimizing downtime associated with disruptive events. Additionally, testing backups allows organizations to assess their recovery plans, evaluate the speed and efficiency of their backup systems, and ensure compliance with regulatory requirements. Inadequate backup processes can lead to extended downtime, critical data loss, financial losses, reputation damage, and noncompliance.

Relationship to Busines Continuity

Continuity of operations (COOP) and business continuity (BC) are closely related concepts that both focus on maintaining the ongoing functioning of an organization during and after a disruption, disaster, or crisis. However, they differ slightly in terms of their scope and primary objectives.

Continuity of operations primarily addresses the continuity of critical functions and services within an organization during an emergency or disaster. It often involves the development and implementation of strategies to maintain or restore essential operations, such as redundant IT systems, off-site backups, and disaster recovery solutions. COOP usually encompasses a shorter time frame, focusing on the immediate response to a disruption and the steps taken to resume critical functions as quickly as possible.

Continuity of operations is a component of the broader business continuity concept. Both are focused on maintaining the ongoing functioning of an organization during disruptions, but COOP is primarily concerned with the immediate response and restoration of critical functions, while business continuity encompasses a more comprehensive approach to ensure the overall resilience and recovery of the entire organization.

Capacity Planning

Capacity planning is a critical process in which organizations assess their current and future resource requirements to ensure they can efficiently meet their business objectives. This process involves evaluating and forecasting the necessary resources in terms of people, technology, and infrastructure to support anticipated growth, changes in demand, or other factors that may impact operations. For people, capacity planning considers the number of employees, their skill sets, and the potential need for additional training or hiring to meet future demands. This may involve evaluating workforce productivity, analyzing staffing levels, and identifying potential skills gaps. In terms of technology, capacity planning encompasses the assessment of hardware, software, and network resources required to support business operations, taking into account factors such as performance, scalability, and reliability.

Organizations must ensure they have the right technology resources in place to handle increasing workloads and support new applications or services. When it comes to infrastructure, capacity planning involves evaluating physical facilities, such as datacenters and office spaces, to determine whether they can accommodate projected growth and maintain business continuity. This may include considerations for power, cooling, and connectivity, as well as planning for potential expansion or relocation. Organizations use various capacity planning methods, including trend analysis, simulation modeling, and benchmarking, to help forecast their needs. Trend analysis examines historical data to identify patterns and trends in resource usage, demand, and performance. Organizations can forecast future resource requirements by understanding past patterns. This type of analysis can help identify potential bottlenecks or other areas that require attention. Simulation modeling leverages computer-based models to simulate real-world scenarios. Organizations can assess the impact of changes in demand, different resource allocation strategies, or system configurations to make informed decisions and optimize resource allocation to meet anticipated needs. Benchmarking requires a comparison of an organization's performance metrics against industry standards or best practices. Benchmarking provides a comparatively simple way to identify areas for improvement and establish performance targets. Ultimately, effective capacity planning allows organizations to optimize resource allocation, reduce costs, and minimize the risk of downtime or performance issues, ensuring they can continue to meet their business goals and maintain a competitive edge.

People Risks Associated with Capacity Planning

People risks associated with capacity planning may include insufficient staffing or skills gaps, leading to inadequate resource allocation or ineffective utilization. Lack of cross-training or succession planning can create dependency on specific individuals, increasing vulnerability to disruptions. Additionally, resistance to change, lack of employee engagement, or ineffective communication can hinder successful security operations.

Cross-Training — Requires employees to develop skills and knowledge outside their primary roles to mitigate the risk of relying heavily on specific individuals or teams. By cross-training employees, organizations can ensure that multiple individuals can perform critical tasks, reducing the dependence on a single employee or team. Cross-training promotes flexibility, resilience, and continuity within the workforce.

Remote Work Plans — Outline strategies for employees to work effectively outside the traditional office environment. Remote work plans define communication channels, technology requirements, and expectations for remote work arrangements. Established remote work plans allow organizations to seamlessly transition to remote operations, ensuring business continuity and minimizing the impact of disruptions.

Alternative Reporting Structures — Describe backup or temporary reporting relationships to reduce the risk associated with single points of failure in management or decision-making. Organizations can maintain operations and decision-making even if key personnel are unavailable by identifying interim individuals or teams.

Effective communication is paramount in reducing risk during disruptive events. Clear and timely communication channels ensure that employees, stakeholders, and customers receive accurate information, instructions, and updates. Clear communication helps manage expectations, reduce confusion, and facilitate coordinated responses. Communication fosters trust, promotes employee engagement, and ensures everyone is aligned with the organization's response plans. Additionally, communication plays a vital role in disseminating information about alternative work arrangements, changes in reporting structures, and other critical updates during a disruptive event.

Technologies and software associated with remote work:

Virtual Private Network (VPN) — Provides secure access to an organization's internal network and resources.

Remote Desktop Software — Allows remote access to computers or virtual desktops in the office or the tools used by the help desk and service-center teams to support employees.

Cloud-Based Tools — Platforms like Microsoft 365, Google Workspace, Dropbox, Slack, and many other popular tools enable remote team collaboration, document sharing, and communication.

Video Conferencing Software — Applications like Zoom, Microsoft Teams, or Webex facilitate virtual meetings, conference calls, and screen sharing.

Instant Messaging and Chat Tools — Applications like Slack, Microsoft Teams, or Discord enable real-time communication and quick collaboration.

Virtual Phone Systems — Cloud-based phone systems allow employees to make and receive calls remotely using their computers or mobile devices.

Project Management Tools — Platforms like Trello, Asana, or Jira assist in task management, project tracking, and team coordination.

Changes in Workforce Capacity

Layoffs can introduce a range of cybersecurity and physical risks to an organization, making it crucial to consider these factors within capacity planning efforts. Disgruntled employees may pose a significant cybersecurity risk, potentially engaging in unauthorized access or misuse of sensitive data and systems. Additionally, the loss of experienced employees may result in insufficient knowledge transfer to the remaining staff, leading to security gaps and misconfigurations. Furthermore, improper revocation of access to systems and data for laid-off employees can leave organizations vulnerable.

In terms of physical risks, departing employees may resort to theft or sabotage of physical assets or exploit their knowledge of safety protocols and procedures to compromise the organization's security. Unauthorized access to premises is another concern if access credentials are not revoked promptly.

Capacity planning is essential in managing these risks. It enables organizations to assess resource requirements and make strategic decisions about staffing levels and resource allocation. By incorporating potential layoffs into capacity planning, organizations can proactively prepare for the associated risks and minimize their impact. Implementing robust offboarding

procedures, ensuring proper knowledge transfer, and maintaining a strong security culture among remaining employees are crucial in mitigating risks. In conclusion, considering the potential risks associated with layoffs during capacity planning helps organizations maintain a secure environment and protect their valuable assets.

Other Risks Associated with Poor Capacity Planning

Poor capacity planning regarding technology and infrastructure can have significant consequences for an organization's cybersecurity and physical security. Overloaded systems resulting from inadequate capacity planning can increase susceptibility to crashes, failures, and denial of service (DoS) attacks. Additionally, limited resources may lead to performance degradation, potentially causing organizations to neglect essential security measures and updates. Failing to invest in the right security technologies or maintain the necessary infrastructure to protect against emerging threats leaves organizations more vulnerable to cyberattacks.

Physically, poor capacity planning may result in insufficient investment in security measures such as access control systems, surveillance cameras, or secure facilities, exposing organizations to unauthorized access or theft. Overlooking capacity requirements for power and cooling can cause overheating or power failures in datacenters, leading to hardware failures, data loss, or downtime. Furthermore, inadequate planning for future growth can limit an organization's ability to scale its operations, potentially affecting its responsiveness to security incidents or implementation of new security measures.

In contrast, overestimating capacity needs during capacity planning can negatively impact an organization. Increased costs from unnecessary expenses on technology, infrastructure, and personnel, strain budgets and divert funds from other critical areas. Inefficient resource utilization can lead to low utilization rates, which can negatively affect the return on investment (ROI) and overall operational effectiveness. Overestimating capacity needs can contribute to higher energy consumption, driving up costs and increasing the organization's carbon footprint and environmental impact.

Deploying more resources than necessary can introduce increased complexity in managing and maintaining technology and infrastructure. This added complexity could create challenges for IT teams, making it more difficult to identify and resolve issues or optimize performance. Additionally, the opportunity cost of investing in excess capacity can be significant, as resources may be diverted from other essential projects or initiatives, potentially hindering innovation or market growth.

To avoid these potential problems, organizations must strive for a balanced approach to capacity planning, considering current and future needs while remaining flexible and adaptable to changing circumstances. Regularly reviewing and updating capacity plans, along with employing techniques such as monitoring, forecasting, and resource scaling, can help organizations optimize resource allocation and mitigate the risks associated with overestimating capacity needs.

Site Considerations

Enterprise environments often provision resiliency at the site level. An alternate processing or recovery site is a location that can provide the same (or similar) level of service. An alternate processing site might always be available and in use, while a recovery site might take longer to set up or only be used in an emergency.

Operations are designed to failover to the new site until the previous site can be brought back online. Failover is a technique that ensures a redundant component, device, application, or site can quickly and efficiently take over the functionality of an asset that has failed. For example, load balancers provide failover in the event that one or more servers or sites behind the load balancer are down or are taking too long to respond. Once the load balancer detects this, it will redirect inbound traffic to an alternate processing server or site. Thus, redundant servers in the load balancer pool ensure there is no or minimal interruption of service.

Site resiliency is described as hot, warm, or cold:

- A hot site can failover almost immediately. It generally means the site is within the organization's ownership and ready to deploy. For example, a hot site could consist of a building with operational computer equipment kept updated with a live data set. Hot sites often have a live connection to your main site with data copied across to the duplicate servers. This is the most costly option.

A warm site could be similar, but with the requirement that the latest data set needs to be loaded.

A cold site takes longer to set up. A cold site may be an empty building with a lease agreement in place to install whatever equipment is required when necessary.

Providing redundancy on this scale is generally very complicated and expensive. Another issue is that creating duplicate sites and data also doubles (or more) the complexity of securing the resources. The same security procedures must apply to redundant sites, spare systems, and backup data as apply to the main copy.

Geographic dispersion refers to the distribution of recovery sites across different geographic locations for disaster recovery (DR) purposes. The concept aims to ensure that recovery sites are located far enough apart to minimize the impact of regional disasters, such as natural calamities or localized incidents. By strategically dispersing recovery sites, organizations can ensure the resilience of their recovery strategies and reduce the risk of a single catastrophic event affecting all business operations.

Cloud as Disaster Recovery (DR)

Several factors drive organizations to use cloud services for datacenter or site redundancy. Cost efficiency plays a significant role, as cloud providers offer more affordable redundancy and backup options due to their economies of scale.

"Economies of scale" is a concept that refers to the cost advantages that businesses can achieve when they increase production and output. Essentially, the more a company produces, the cheaper it becomes to deliver those products.

The scalability of cloud services allows businesses to incorporate redundant capabilities without over-provisioning resources. For example, geographic diversity provided by cloud providers helps protect against regional outages or disasters, but incorporating this type of redundancy for a private organization would be cost-prohibitive and unwarranted.

Faster deployment of capabilities when using cloud platforms enables organizations to set up and deploy redundant systems quickly, far more rapidly than could be done when building infrastructure from scratch.

Simplified management is another critical factor, with cloud providers offering tools and services that reduce the complexity of managing redundant infrastructure. Improved security and compliance are also important considerations, as cloud providers invest heavily in these areas, helping organizations meet data protection and redundancy regulatory requirements.

Diversity and Defense in Depth

Platform diversity is a concept in cybersecurity that refers to using multiple technologies, operating systems, and hardware or software components within an organization's infrastructure. By incorporating a variety of platforms, businesses can reduce the risk of a single vulnerability or attack affecting their entire infrastructure. This approach is important for cybersecurity operations, as it helps create a more resilient environment that can better withstand cyber threats.

When an organization relies on a single technology or platform, an attacker who discovers a vulnerability can potentially compromise the entire system. However, with platform diversity, even if one component is compromised, other parts of the system remain secure, limiting the potential damage. Furthermore, a diverse technology landscape can make it more challenging for threat actors to navigate, as they must be familiar with multiple platforms and exploit techniques. In this way, platform diversity deters potential attackers and contributes to the overall robustness of an organization's cybersecurity posture.

Testing Resiliency

Testing system resilience and incident response effectiveness are crucial for organizations to recover from disruptions and maintain business continuity. By conducting various tests, organizations can identify potential vulnerabilities, evaluate the efficiency of their recovery strategies, and improve their overall preparedness for real-life incidents.

Tabletop Exercises involve teams discussing and working through hypothetical scenarios to assess their response plans and decision-making processes. These exercises help identify knowledge, communication, and coordination gaps, ultimately strengthening the organization's incident response capabilities. For example, a tabletop exercise might simulate a ransomware attack to test how well the organization's IT and management teams collaborate to mitigate the threat and restore operations.

Failover Tests involve intentionally causing the failure of a primary system or component to evaluate the automatic transfer of operations to a secondary, redundant system. These tests ensure backup systems can seamlessly take over during an actual incident, minimizing downtime and data loss. For example, a failover test could involve simulating the failure of a primary database server to verify that a standby server can successfully assume its role and maintain service continuity.

Simulations are controlled experiments replicating real-world scenarios, allowing organizations to assess their incident response processes and system resilience under realistic conditions. These tests can reveal potential bottlenecks, inefficiencies, or vulnerabilities that might not be apparent in less complex tests. For instance, a simulation might involve a cyberattack targeting the organization's network infrastructure to evaluate the effectiveness of security measures and the ability to detect, contain, and remediate the threat.

Parallel Processing Tests involve running primary and backup systems simultaneously to validate the functionality and performance of backup systems without disrupting normal operations. These tests help organizations ensure their backup systems can handle the same workload as primary systems during an incident. For example, an organization might run parallel processing tests to verify that a backup datacenter can manage the same traffic and processing demand as the primary datacenter in an outage.

Failure to perform tests such as tabletop exercises, failover tests, simulations, and parallel processing can expose organizations to significant risks. With these tests, organizations can recognize potential vulnerabilities and weaknesses in their incident response plans and system resilience designs and use the results of tests to improve existing plans. In a real-life disruption or cyberattack, untested systems and response procedures may fail to perform as expected, leading to extended downtime, data loss, and reputational damage. Moreover, unprepared organizations may face increased costs related to incident recovery and mitigation and potential regulatory penalties for failing to meet industry standards and compliance requirements. Ultimately, failure to implement these tests can leave organizations inadequately prepared for crises, undermining their ability to maintain business continuity and protect valuable assets.

Documentation

Business continuity documentation practices cover planning, implementation, and evaluation. Documentation supports the testing process. Documentation includes test plans outlining the objectives, scope, and methods of tests and the roles and responsibilities of individuals involved. Test scripts (or scenarios) provide step-by-step instructions for performing the tests, and test results identify strengths and weaknesses of the business continuity plan and the technical capabilities supporting it. Documentation is the foundation for clear communication and reporting of activities. It provides a common reference point for those involved in business continuity testing and facilitates effective communication with management, executive teams, and other relevant stakeholders. Third-party assessments and certifications offer an objective and independent evaluation of an organization's testing practices. Third-party assessments and certifications offer objective evaluation, compliance verification, validation of testing effectiveness, industry recognition, and recommendations for continuous improvement. Examples of third-party evaluations include assessments performed in alignment with ISO 22301, PCI DSS, and SOC 2.

12.1.7 Practice Questions (Section Quiz)

q_risk_types_tol_avoidance_secp8

A company identifies a potential security risk associated with the implementation of a new system. However, after assessing the risk, the company decides not to implement any measures to address this specific risk.

Which of the following risk management strategies is the company employing?

Answers:

***Avoidance**

Transference

Mitigation

Exemption

Explanation:

The avoidance strategy means that the organization will not proceed with actions likely to trigger the risk.

Transferring risk means shifting the risk to a third party, typically through insurance or outsourcing. This is not what the company is doing in this scenario.

Mitigation involves taking steps to reduce the severity or likelihood of the risk. In this scenario, the company is not implementing any measures to address the risk, so they are not mitigating it.

Exemption is generally a formal process documented and approved by risk managers or senior executives. The company chooses not to address the risk without indication of any formal exemption process, which is more aligned with risk avoidance.

q_risk_types_tol_inherent_risk_secp8

A small engineering company wants to run a business analysis. It hired a consulting firm to better understand the underlying components, including the result of quantitative or qualitative risk analysis.

Which of the following values is MOST beneficial to the company in this situation?

Answers:

***Inherent risk**

Annualized loss expentancy (ALE)

Risk factors

Single loss expentency (SLE)

Explanation:

The result of quantitative or qualitative analysis is a measure of inherent risk. Inherent risk is the level of risk before implementing mitigation.

ALE is the amount a company would lose over the course of a year. The calculation for ALE is the multiplication of SLE by the annualized rate of occurrence (ARO).

The SLE is the amount a company would lose in a single risk factor occurrence. The calculation for SLE is the multiplication of the asset value by an exposure factor (EF).

A risk factor is an item used as a risk input during quantitative or qualitative analysis.

q_risk_types_tol_mttr_01_secp8

A company experiences a significant system failure that leads to service interruption. The IT department works to restore the system and documents the duration it takes to fix the problem.

This recorded duration is primarily indicative of which of the following options?

Answers:

***Mean time to repair (MTTR)**

Risk assessment

Mean time between failures (MTBF)

Risk tolerance

Explanation:

Mean time to repair (MTTR) measures the average time required to repair a failed component or system.

Risk assessment involves identifying, evaluating, and prioritizing risks. This process doesn't primarily involve recording the duration of system repairs.

Mean time between failures (MTBF) measures the anticipated time between system failures during operation. This metric doesn't primarily concern the time taken to repair a system after it has failed.

Risk tolerance refers to the amount of risk that an organization is willing to accept in its operations. It does not primarily involve the duration of system repairs.

q_risk_types_tol_mttr_02_secp8

A risk manager for a company providing IT support services conducts a business impact analysis (BIA) and identifies a mission essential function (MEF) that relies on a server with a mean time between failures (MTBF) of 2,500 hours and a mean time to repair (MTTR) of 4 hours.

Given a maximum tolerable downtime (MTD) of 24 hours and a recovery time objective (RTO) of 6 hours for this function, what should the risk manager prioritize in the risk management strategy?

Answers:

Improving the MTBF of the server.

***Reducing the MTTR of the server.**

Increasing the MTD for the function.

Extending the RTO for the function.

Explanation:

Reducing the MTTR is crucial. With an RTO of 6 hours and an MTTR of 4 hours, other activities have limited time, such as recovery during the maximum tolerable downtime. Lowering the MTTR provides more time for those activities.

The current MTBF of 2,500 hours is substantial and not an immediate concern considering the MTD of 24 hours.

Increasing the MTD might not be feasible or desirable. The risk manager sets the MTD based on the disruption the business can tolerate.

Extending the RTO is not the best option. The current RTO of 6 hours seems adequate, considering the MTTR of 4 hours. The focus should be on restoring the server within the RTO.

q_risk_types_tol_mttr_mtbf_01_secp8

A company is reviewing its system reliability metrics. It needs to know the average time the system operates without failure and the average time it takes to repair a system when it fails.

Which of the following pairs of metrics should the company focus on to meet its needs?

Answers:

***Mean time between failures (MTBF) and mean time to repair (MTTR)**

Recovery time objective (RTO) and recovery point objective (RPO)

Risk tolerance and risk appetite

Risk assessment and risk analysis

Explanation:

MTBF measures the average time a system or component expects to operate without failure during typical operation. MTTR is the average time required to repair a failed component or device.

RTO and RPO are measures of the acceptable amount of data loss or downtime in case of a disaster, not measurements of system reliability or repair times.

Risk tolerance and risk appetite are not terms used to describe the metrics related to system failure and recovery.

Risk assessment and risk analysis are processes involved in identifying and evaluating risks and do not provide measurements for system reliability or repair times.

q_risk_types_tol_mttr_mtbf_02_secp8

A manufacturing organization identifies its server maintenance and repair process as a mission-essential function. The company experienced three server failures in the last year, each failure taking approximately six hours to repair and restore operations.

Given the company's performance metrics and assuming all failures occurred during operational hours, what are the MTBF and MTTR for the organization's server maintenance and repair process?

Answers:

MTBF: 2,000 hours/failure, MTTR: 6 hours

MTBF: 1,000 hours/failure, MTTR: 2 hours

***MTBF: 2,920 hours/failure, MTTR: 6 hours**

MTBF: 1,460 hours/failure, MTTR: 18 hours

Explanation:

The MTTR (mean time to repair) is 6 hours, which is the time it took to repair and restore operations for each failure. The MTBF (mean time between failures) is 2,920 hours/failure, calculated by dividing the total operational time of 8,760 hours per year by 3 failures.

Incorrect MTTR answers include 2 hours and 18 hours, as it took 6 hours to restore operations for each failure.

Incorrect MTBF answers include 2,000, 1,000, and 1,460 hours/failure. The correct MTBF should be 2,920 hours/failure, calculated by dividing the total operational time of 8,760 hours per year by 3 failures.

q_risk_types_tol_mttr_mtbf_03_secp8

Which of the following statements accurately distinguish the differences between mean time to repair (MTTR) and mean time between failures (MTBF)?

Answers:

***MTTR describes how long it would take to bring equipment back into operation, while the MTBF refers to how long equipment will last until it is no longer operational.**

MTTR refers to how long equipment will last until it is no longer operational, while the MTBF describes how long it would take to bring equipment back into operation.

MTTR is the amount of data loss that a system can sustain, measured in time, while MTBF is the longest period of time that a business function outage may occur without causing irrecoverable business failure.

MTBF is the amount of data loss that a system can sustain, measured in time, while MTTR is the longest period of time that a business function outage may occur for without causing irrecoverable business failure.

Explanation:

Mean time to repair (MTTR) is a measure of the time taken to correct a fault so that the company can bring a system back to full operation. We can also describe this as the mean time to replace or recover.

Mean time between failures (MTBF) represents the expected lifetime of a product.

The recovery point objective (RPO) is the amount of data loss that a system can sustain, measured in time.

Maximum tolerable downtime (MTD) is the longest period of time that a business function outage may occur without causing irrecoverable business failure.

q_risk_types_tol_mttr_mtbf_04_secp8

Which of the following statements accurately distinguishes the similarities between mean time to repair (MTTR) and mean time between failures (MTBF)?

Answers:

***Both MTTR and MTBF can determine the amount of asset redundancy a system should have.**

Both MTTR and MTBF are for non-repairable assets.

The MTBF and MTTR calculations are the same.

MTTR is the median time it takes to correct a fault, while MTBF is the average time it takes to correct a fault.

Explanation:

The similarity is that MTTR and MTBF can determine the amount of asset redundancy a system should have. A redundant system can fail over to another asset if there is a fault and continue to operate normally.

MTTR is for repairable assets, while MTBF is meant for non-repairable assets.

The calculation for MTBF is the total time divided by the number of failures. The calculation for MTTF is the total time divided by the number of devices.

MTTR is the average measure of the time taken to correct a fault so that the system restores to full operation. MTBF is the average time between failures.

q_risk_types_tol_percentage_secp8

An organization is expanding its operations into a new region with unfamiliar regulatory requirements. The risk management team conducts a thorough risk assessment and identifies a need for robust controls to ensure compliance.

Which of the following would be the MOST effective metric for tracking regulatory compliance risk in this situation?

Answers:

***The percentage of employees who have undergone compliance training.**

The total revenue generated from the new region.

The number of identified market competitors.

The frequency of audits conducted by the regulatory authority.

Explanation:

The percentage of employees who have undergone compliance training is the most relevant for managing regulatory compliance risk. Training employees on the new regulatory requirements ensure that they understand the rules and can act in compliance with them.

While revenue is an important business metric, it does not directly measure regulatory compliance risk.

The number of competitors may provide insights into market competition, but it does not directly measure regulatory compliance risk.

While audit frequency is a measure of regulatory scrutiny, the primary control for ensuring compliance lies in the organization's internal practices, not in the frequency of external audits.

q_risk_types_tol_qualitative_quantitative_secp8

A cybersecurity consultant is assessing risks for a new e-commerce website. The consultant identifies potential risks, evaluates their impact and likelihood, and considers the organization's ability to mitigate them.

Which risk assessment methodology is the consultant MOST likely using?

Answers:

Qualitative

Quantitative

***Qualitative and quantitative**

Ad hoc

Explanation:

The consultant considers both qualitative and quantitative factors. Qualitative factors include the risk's impact and likelihood of occurring, while quantitative factors would be the ability to mitigate risks in the risk assessment.

The consultant considers qualitative factors, such as impact and likelihood. However, the consultant must also consider the organization's ability to mitigate risks involving quantitative factors, such as costs.

The consultant must also consider qualitative factors, like impact and likelihood, and not exclusively quantitative factors.

Consultants conduct ad hoc assessments as needed, often responding to specific incidents. However, the scenario does not suggest or mention that this assessment is in response to a specific incident.

q_risk_types_tol_quantitative_secp8

The IT department at a multinational organization is evaluating potential risks associated with implementing a new network infrastructure. This includes identifying potential vulnerabilities, estimating potential downtime, and assessing the financial impact of potential cyberattacks.

Which type of risk assessment BEST suits the organization's requirements?

Answers:

***Quantitative risk assessment**

Qualitative risk assessment

Ad hoc risk assessment

Continuous risk assessment

Explanation:

Quantitative risk assessment allows the team to measure risk in terms of loss and occurrence by using numerical or measurable data.

While the qualitative risk assessment method categorizes risks into levels, it does not provide the exact numerical data the IT team needs for their assessment.

Ad hoc risk assessment is not the first choice as this type of assessment is usually carried out in response to an immediate threat or incident and might not provide a comprehensive review of all the potential risks.

While continuous risk assessment emphasizes ongoing evaluation and updating of the risk assessment process, it's not inherently quantitative or qualitative. In this scenario, the team is specifically looking for measurable data.

q_risk_types_tol_regulatory_compliance_secp8

A multinational company is looking to ensure that its global operations meet all the relevant legal requirements to avoid fines, penalties, and potential loss of reputation.

What type of process is the company planning to implement?

Answers:

***Regulatory compliance**

Risk threshold

Risk management

Audit

Explanation:

A regulatory process refers to a set of procedures to ensure that a company's operations meet the legal and regulatory requirements in their jurisdictions.

The risk threshold is the point when risks become unacceptable. The company is looking for regulatory compliance, which is not a risk to ignore in a risk threshold.

While risk management is a broader process that includes identifying, assessing, and prioritizing risks, it is not specific to adhering to legal and regulatory requirements.

An audit is a process of reviewing an organization's operations, procedures, or financials. While it may check compliance with regulations, it is different from the process of adhering to them.

q_risk_types_tol_residual_secp8

Your company has developed and implemented countermeasures for the greatest risks to their assets. However, there is still some risk left.

What is the remaining risk called?

Answers:

Exposure

Risk

Loss

***Residual risk**

Explanation:

Residual risk is the portion of risk that remains after the implementation of a countermeasure. There is almost always some residual risk.

Exposure is the vulnerability of losses from a threat agent, and risk is the likelihood of a vulnerability being exploited.

A loss is the real damages to an asset that reduces its confidentiality, integrity, or availability.

Risk is a generic term referring to risk management, which involves identifying potential issues, assessing their potential impact on the organization, and implementing controls to mitigate them.

q_risk_types_tol_risk_acceptance_secp8

A new company implements a data center that will hold proprietary data that is output from a daily workflow. As the company has not received any funding, no risk controls are in place.

How does the company approach risk during operations?

Answers:

***Risk acceptance**

Risk avoidance

Risk mitigation

Risk transference

Explanation:

Risk acceptance means that the company did not put in place countermeasures, either because the level of risk does not justify the cost or because there will be an unavoidable delay before the company can deploy the countermeasures.

Risk avoidance means that a company can stop an activity that is risk-bearing. The discontinuation of a defective product is a form of risk avoidance.

Risk mitigation is the overall process of reducing exposure to the effects of risk factors. An example is deploying a countermeasure that reduces exposure to a threat or vulnerability.

Risk transference means assigning risk to a third party, such as an insurance company or a contract with a supplier that defines liabilities.

q_risk_types_tol_risk_appetite_secp8

A company is looking to expand its business into new markets despite associated risks. It prepares to accept higher risks for potentially higher returns.

Which of the following approaches BEST meets the company's risk management approach parameters?

Answers:

***Risk appetite**

Risk threshold

Risk tolerance

Risk mitigation

Explanation:

Risk appetite refers to the level of risk an organization is willing to accept in pursuit of its objectives. The company has an "appetite" for a certain amount of risk.

The risk threshold is the point when risks become unacceptable. They're looking at the company's willingness to accept risk, not the point at which the risk becomes unacceptable.

Risk intolerance is an organization's unwillingness to accept risk. The company is willing to accept higher risks for potentially higher returns, making it tolerant of some level of risk.

Risk mitigation is the process of developing actions and plans to decrease the risks to an organization. The question is asking about the company's approach to accepting risks.

q_risk_types_tol_risk_assessment_01_secp8

A global corporation assesses risk appetite and how risks in various regions could influence mission-critical operations. It is assessing compliance with local laws and licensing requirements to prevent financial risk or resolve security risks, changing the risk posture, and implementing risk controls to compensate.

What type of assessment is the team performing?

Answers:

***Risk control assessment**

Site risk assessment

Vulnerability assessment

Penetration testing

Explanation:

Risk and control self-assessment (RCSA) is the method by which companies evaluate and analyze the operational risks and the efficacy of the controls used to manage them.

A site risk assessment evaluates exposure to safety concerns related to area-related risks, such as disaster risk, utility disruption, or health and safety concerns.

A vulnerability assessment is a comprehensive analysis of the security vulnerabilities of an information system. Automated vulnerability software, such as Nessus, is sometimes used.

Penetration testing is a simulated cyberattack on a computer system to discover any exploitable vulnerabilities.

q_risk_types_tol_risk_assessment_02_secp8

The security team at a company is adopting a cybersecurity framework to standardize its security measures across different departments. The team lead wants to ensure that the selected framework encompasses all the critical aspects of cybersecurity.

What should the security team lead ensure the cybersecurity framework covers to provide a comprehensive security posture?

Answers:

Procedures for incident response

Threat intelligence and event correlation

The technical controls and access management

***Risk assessment, incident response, access control, awareness, and training**

Explanation:

Risk assessment, incident response, access control, awareness, and training are the vital components of a comprehensive cybersecurity framework. They ensure that well-rounded security measures are effective against a variety of threats.

Although incident response is a critical aspect of cybersecurity, a comprehensive cybersecurity framework must cover much more than just incident response.

While these components are essential for proactive threat management, a comprehensive cybersecurity framework requires more components, including risk assessment, incident response, access control, and training.

Even though these components are important for securing the system, a comprehensive framework should also include risk assessment, incident response, awareness, and training for a well-rounded security posture.

q_risk_types_tol_risk_impact_01_secp8

A company is evaluating the potential outcomes of a certain risk event. It estimates that if the event occurs, it could lead to a financial loss measured in dollars.

Which of the following outcomes can the company conclude in this scenario?

Answers:

***Impact**

Risk tolerance

Exposure factor

Annualized loss expectancy (ALE)

Explanation:

The impact is the potential loss incurred if a risk event occurs. The financial loss that could result from the risk event represents the impact of that event.

Risk tolerance refers to the amount of risk that an organization is willing to accept. The scenario did not define the amount of risk it will accept.

The exposure factor is the percentage of loss an organization would experience during specific asset violations or damage. The measurement described is dollars and not a percentage.

Annualized loss expectancy (ALE) is the potential yearly cost of all instances of a specific risk. The scenario does not provide information about how often the risk event might occur annually.

q_risk_types_tol_risk_impact_02_secp8

A company has recently identified a potential risk involving its inventory management software. The company's risk manager has conducted an initial assessment and listed the risk in the risk register.

As a result, the manager must decide on a suitable response to this risk.

Which of the following is the MOST appropriate step for the risk manager?

Answers:

Identify and assess the potential vulnerabilities and threats associated with the risk

Identify the mission essential functions of the company and assess the risk's impact on them

***Determine the likelihood and impact of the risk on the company's operations**

Update the risk register with the mitigation strategies and inform the stakeholders

Explanation:

Determine the likelihood and impact of the risk on the company's operations before deciding on the appropriate risk response. The risk manager must understand these factors to determine whether to accept, mitigate, transfer, or avoid the risk.

The risk manager identifies and assesses vulnerabilities and threats during the risk identification process before deciding on the risk response.

The risk manager should have identified mission essential functions during the initial risk identification and assessment process.

The risk manager updates the risk register with the mitigation strategies, informing the stakeholders as the final step in the risk management process.

q_risk_types_tol_risk_tolerance_secp8

A company is willing to accept certain risks associated with a new project as it believes the potential rewards outweigh the potential downsides. However, it will not accept risks that jeopardize its core business functions.

What does this decision about the company's risk management approach primarily represent?

Answers:

***Risk tolerance**

Risk threshold

Risk appetite

Risk transference

Explanation:

Risk tolerance refers to the degree of variability in investment returns an organization is willing to withstand. The company's willingness to accept certain risks for a new project, but not those that could endanger core business functions, is an example of defining its risk tolerance.

The risk threshold is the specific point at which risk becomes unacceptable and requires action.

Risk appetite is the amount of risk an organization is willing to seek or accept to achieve its long-term objectives. However, the question is more focused on the company's risk tolerance.

Risk transference involves shifting the risk to another party, typically through insurance or outsourcing. The scenario does not involve transferring risk to another party.

q_risk_types_tol_risk_transference_01_secp8

A technology company experiences several security vulnerabilities with its online application, leading to customer complaints and legal threats. In response, the board of directors is considering outsourcing the maintenance of the application to a third party.

Which risk management strategy is the company primarily implementing?

Answers:

Risk avoidance

Risk acceptance

Risk mitigation

***Risk transference**

Explanation:

The company is transferring the risk to a third party by outsourcing the maintenance of the application, which is an example of risk transference.

Risk avoidance involves halting the risky activity. In this scenario, the company is not stopping its operations but shifting the maintenance to a third party.

Risk acceptance means the company has not deployed countermeasures because it has deemed the risk level acceptable. This is different from the company actively seeking a solution, indicating it is not accepting the risk.

Mitigation involves implementing controls to lessen the likelihood or impact of risk. Here, the company is not implementing controls but transferring the task to a third party.

q_risk_types_tol_risk_transference_02_secp8

A company relies on a legacy system for a core business process, but the system's vendor no longer provides security patches. To manage the risks associated with this system, the company decides to contract a third-party provider to take on this risk.

What strategy is the company using?

Answers:

***Risk transference**

Risk acceptance

Risk mitigation

Patch management

Explanation:

The company is transferring the risk associated with the inability to patch the legacy system to a third-party provider.

Risk acceptance involves accepting the risk without taking further steps to reduce its impact. Since the company is taking steps to manage the risk, this option does not apply.

Risk mitigation refers to efforts to reduce the impact of a risk. Contracting a third-party provider to manage the risk is not a risk mitigation strategy but a risk transference strategy.

Patch management is the process of managing updates for software applications. However, in this scenario, the company cannot patch the system, so patch management is not the strategy used.

q_risk_types_tol_risk_transference_03_secp8

A business utilizes an outdated system essential to its operations, but the supplier no longer offers updates for security flaws.

In response to the vulnerabilities linked to this system, the business chooses to engage an external provider to assume responsibility for this risk.

What approach is the business employing to handle this situation?

Answers:

***Risk transference**

Risk acceptance

Risk mitigation

Patch management

Explanation:

The company is transferring the risk associated with the inability to patch the legacy system to a third-party provider.

Risk acceptance involves accepting the risk without taking further steps to reduce its impact. Since the company is taking steps to manage the risk, this option does not apply.

Risk mitigation refers to efforts to reduce the impact of a risk. Contracting a third-party provider to manage the risk is not a risk mitigation strategy but a risk transference strategy.

Patch management is the process of managing updates for software applications. However, in this scenario, the company cannot patch the system, so patch management is not the strategy used.

q_risk_types_tol_rpo_01_secp8

An organization is continuously backing up its data to ensure minimum data loss in case of a system failure. It is trying to decide the maximum age of files that require recovery from backup storage for normal operations to resume after a failure.

What concept should the organization consider to meet their needs?

Answers:

***Recovery point objective (RPO)**

Single loss expectancy (SLE)

Recovery time objective (RTO)

Annualized loss expectancy (ALE)

Explanation:

A recovery point objective (RPO) is the maximum acceptable age of data that an organization can tolerate losing. When an organization continuously backs up its data, it is typically aiming to keep its RPO as low as possible.

Single loss expectancy (SLE) is a term used in risk assessment to represent the expected loss for any single event. It does not directly relate to data backup frequency or data age considerations.

While recovery time objective (RTO) and RPO are both important disaster recovery considerations, RTO does not determine the acceptable age of data for recovery.

Annualized loss expectancy (ALE) is not a measure related to the age of data that needs recovery after a failure.

q_risk_types_tol_rpo_02_secp8

A technology company implements a backup strategy to mitigate data loss in case of a system crash. The strategy focuses on defining the maximum duration of data to retrieve from the backup storage to ensure business continuity after a system crash.

Which principle should the company applying to meet their needs?

Answers:

***Recovery point objective (RPO)**

Single loss expectancy (SLE)

Recovery time objective (RTO)

Annualized loss expectancy (ALE)

Explanation:

A recovery point objective (RPO) is the maximum acceptable age of data that an organization can tolerate losing. When an organization continuously backs up its data, it is typically aiming to keep its RPO as low as possible.

Single loss expectancy (SLE) is a term used in risk assessment to represent the expected loss for any single event. It does not directly relate to data backup frequency or data age considerations.

While recovery time objective (RTO) and RPO are both important disaster recovery considerations, RTO does not determine the acceptable age of data for recovery.

Annualized loss expectancy (ALE) is not a measure related to the age of data that needs recovery after a failure.

q_risk_types_tol_rto_01_secp8

An organization performs a business impact analysis to identify potential effects of business interruptions. It is trying to identify the maximum acceptable time its key business process can be down before it severely impacts operations.

What is the organization attempting to determine?

Answers:

***Recovery time objective (RTO)**

Mean time to repair (MTTR)

Mean time between failures (MTBF)

Annualized rate of occurrence (ARO)

Explanation:

RTO defines the maximum time an organization can tolerate downtime of a particular business process or system before the impact becomes unacceptable.

MTTR refers to the average time a device will take to recover from failure, not a concept directly resulting from a business impact analysis.

MTBF is the expected amount of time a device or product will last in operation between failures and does not factor into the determination of acceptable downtime in a business impact analysis.

ARO is a risk management term referring to the expected frequency of a risk occurring in a year.

q_risk_types_tol_rto_02_secp8

A healthcare institution is conducting a risk assessment to evaluate the implications of potential system downtime.

The team wants to pinpoint the maximum allowable duration that a crucial healthcare system can be nonfunctional before seriously affecting hospital operations.

What is the institution trying to establish in this situation?

Answers:

***Recovery time objective (RTO)**

Mean time to repair (MTTR)

Mean time between failures (MTBF)

Annualized rate of occurrence (ARO)

Explanation:

RTO defines the maximum time an organization can tolerate downtime of a particular business process or system before the impact becomes unacceptable.

MTTR refers to the average time a device will take to recover from failure, not a concept directly resulting from a business impact analysis.

MTBF is the expected amount of time a device or product will last in operation between failures and does not factor into the determination of acceptable downtime in a business impact analysis.

ARO is a risk management term referring to the expected frequency of a risk occurring in a year.

q_anylz_risk_ad_hoc_secp8

A company decides to conduct a risk assessment only once due to a specific change in its infrastructure. This decision to conduct the risk assessment is not part of its regular risk management process.

What type of risk assessment does this situation describe?

Answers:

***Ad hoc**

Recurring

Continuous

Quantitative

Explanation:

Ad hoc risk assessments are those conducted in response to specific organizational events or changes that are not part of the regular risk management process.

A recurring risk assessment is a type of risk assessment conducted on a regular, predetermined schedule. In this case, the company conducted the assessment once.

Continuous risk assessment is an approach where the company conducts assessments on a continuous, ongoing basis. This does not apply to the scenario in the question. It describes a one-time risk assessment.

Quantitative risk assessment involves using numerical measurements to assess the probability and consequences of risks. The type of risk assessment described in the question does not support methodology used to conduct the assessment.

q_anylz_risk_ale_01_secp8

You have conducted a risk analysis to protect a key company asset. You identify the following values:

Asset value = 400

Exposure factor = 75

Annualized rate of occurrence (ARO) = .25

Countermeasure A has a cost of 320 and protects the asset for four years. Countermeasure B has an annual cost of 85. An insurance policy to protect the asset has an annual premium of 90.

What should you do?

Answers:

***Accept the risk or find another countermeasure.**

Implement countermeasure A.

Implement countermeasure B.

Purchase the insurance policy.

Explanation:

In this scenario, you should either accept the risk or find a cheaper countermeasure. The cost of either countermeasure or the insurance policy exceeds the annualized loss expectancy (ALE) of the asset. The ALE = the asset value (400) x the exposure factor (.75) x the ARO (.25) = 75. Based on these calculations, you would expect an annual loss of 75.

Countermeasure A has an annual cost of 80, countermeasure B has an annual cost of 85, and the insurance premium has an annual cost of 90 (all of which cost more than the expected annual loss).

q_anylz_risk_ale_02_secp8

You have conducted a risk analysis to protect a key company asset. You identify the following values:

Asset value = 400

Exposure factor = 75

Annualized rate of occurrence = .25

What is the annualized loss expectancy (ALE)?

Answers:

25

***75**

100

175

475

Explanation:

To calculate the ALE, use the following formula:

Asset value (AV) x exposure factor (EF) x annualized rate of occurrence (ARO) => 400 x 75% x .25 = 75

q_anylz_risk_ale_03_secp8

A company's risk management team has identified a particular risk that carries a significant financial cost. The team has also determined the frequency at which this risk event is likely to occur over a year.

Based on these criteria, what is the company trying to calculate?

Answers:

***Annualized loss expectancy (ALE)**

Single loss expectancy (SLE)

Risk threshold

Exposure factor

Explanation:

The company calculates ALE by multiplying the SLE, the expected monetary loss from a single risk event, by the annualized rate of occurrence (ARO).

While the SLE is part of the ALE calculation, it represents the expected monetary loss from a single risk event and does not include the frequency of the event.

The risk threshold refers to the level of risk an organization is willing to accept or tolerate. It does not utilize the financial cost of a risk event and its frequency of occurrence in its calculations.

Exposure factor is a percentage that represents the magnitude of loss a potential risk event would have on a specific asset, not the annualized financial cost of a risk.

q_anylz_risk_ale_04_secp8

An organization's risk assessment team has flagged a particular risk event that poses a substantial financial threat in every financial quarter.

What is the team aiming to compute based on these parameters?

Answers:

***Annualized loss expectancy (ALE)**

Single loss expectancy (SLE)

Risk threshold

Exposure factor

Explanation:

To calculate ALE, the team multiplies the SLE, the expected monetary loss from a single risk event, by the annualized rate of occurrence (ARO).

While the SLE is part of the ALE calculation, it represents the expected monetary loss from a single risk event and does not include the frequency of the event.

The risk threshold refers to the level of risk an organization is willing to accept or tolerate. It does not utilize the financial cost of a risk event and its frequency of occurrence in its calculations.

Exposure factor is a percentage that represents the magnitude of loss a potential risk event would have on a specific asset, not the annualized financial cost of a risk.

q_anylz_risk_appetite_levels_secp8

As the chief risk officer of a rapidly growing tech startup, you are tasked with setting the company's risk appetite.

The company is in a strong financial position and is looking to aggressively expand its market share. The board of directors has expressed their willingness to take on more risk to achieve this goal.

Which of the following levels of risk appetite would you recommend?

Answers:

Minimalist

Cautious

Balanced

***Expansionary**

Aggressive

Explanation:

Expansionary is the correct answer. This level of risk appetite is correct because it involves a high tolerance for risk. It is suitable for organizations that are in a strong financial position and are looking to aggressively expand their market share, which aligns with the tech startup's situation in this scenario.

The minimalist level of risk appetite is incorrect because it involves taking on the least amount of risk possible. This approach is typically used by organizations that prioritize stability over growth, which is not the case for the tech startup in this scenario.

The cautious level of risk appetite is incorrect because it involves a low tolerance for risk. While it may be suitable for organizations that are focused on steady, incremental growth, it is not appropriate for a company that is looking to aggressively expand its market share.

The balanced level of risk appetite is incorrect because it involves a moderate level of risk. While it may be suitable for organizations that are looking to balance growth with stability, it is not appropriate for a company that is looking to aggressively expand its market share.

The aggressive level of risk appetite is incorrect because it involves the highest level of risk tolerance. While it may be suitable for organizations that are willing to take on significant risk for the potential of high returns, it could also lead to substantial losses. The board of directors has expressed their willingness to take on more risk, but they have not indicated a willingness to take on the highest level of risk.

q_anylz_risk_aro_01_secp8

What is the term for the average number of times that a specific risk is likely to be realized in a single year?

Answers:

Annualized loss expectancy

***Annualized rate of occurrence**

Estimated maximum downtime

Exposure factor

Explanation:

Annualized rate of occurrence (ARO) is the average number of times that a specific risk is likely to be realized in a single year.

Annualized loss expectancy (ALE) is ARO x SLE (single loss expectancy), which is the estimated per-year loss due to exposures.

Estimated maximum downtime sounds similar to maximum tolerable downtime or recovery time objective, neither of which are related to the average number of times a risk is likely to be realized.

Exposure factor is the percentage of value loss that is experienced due to an exposure rather than the number of times of exposure.

q_anylz_risk_aro_02_secp8

When conducting a risk assessment, how is the annualized rate of occurrence (ARO) calculated?

Answers:

Multiply the value of the asset by an exposure factor (EF).

***Through historical data provided by insurance companies and crime statistics.**

Divide the value of the asset by an exposure factor (EF).

Multiply the single loss expectancy (SLE) times the annual rate of occurrence (ARO).

Explanation:

The annualized rate of occurrence (ARO) is the likelihood of a risk occurring within one year. Historical data provides the basis for the statistical probability of the risk occurring. This information is frequently obtained from insurance companies, law enforcement agencies, and computer incident-monitoring organizations. ARO is typically expressed in percent or decimal form.

Single loss expectancy (SLE) is calculated by multiplying the value of the asset by an exposure factor (EF).

Dividing the value of the asset by an exposure factor (EF) is not a valid quantitative analysis formula.

Exposure factor (EF) is calculated by multiplying the single loss expectancy (SLE) times the annual rate of occurrence (ARO).

q_anylz_risk_aro_03_secp8

A company's risk management team has been analyzing a potential risk to its operations. They have identified the probability of the risk event occurring, and they wish to express this probability on a yearly basis.

What is the company trying to calculate?

Answers:

***Annualized rate of occurrence (ARO)**

Annualized loss expectancy (ALE)

Single loss expectancy (SLE)

Risk threshold

Explanation:

The ARO represents the estimated expected frequency that a risk occurs on a yearly basis.

The ALE calculation combines the ARO with the SLE, representing the annual expected loss from a risk, but is not a direct translation of a risk's probability to a yearly rate.

SLE represents the financial impact of a risk event occurring once, not the frequency or probability of the risk over a year.

The risk threshold is the level of risk an organization is willing to accept, which is different from the concept of estimating the frequency of a risk event on a yearly basis.

q_anylz_risk_aro_04_secp8

A financial institution's risk assessment department evaluates a potential threat that could disrupt its financial transactions. They have quantified the likelihood of this risk event happening and aim to project this probability over an annual period.

What metric are they attempting to establish?

Answers:

***Annualized rate of occurrence (ARO)**

Annualized loss expectancy (ALE)

Single loss expectancy (SLE)

Risk threshold

Explanation:

The ARO represents the estimated expected frequency that a risk occurs on a yearly basis.

The ALE calculation combines the ARO with the SLE, representing the annual expected loss from a risk, but is not a direct translation of a risk's probability to a yearly rate.

SLE represents the financial impact of a risk event occurring once, not the frequency or probability of the risk over a year.

The risk threshold is the level of risk an organization is willing to accept, which is different from the concept of estimating the frequency of a risk event on a yearly basis.

q_anylz_risk_calculate_secp8

Which of the following are main variables in calculating risks? (Select two.)

Answers:

***Probability**

***Likelihood**

Risk mitigation cost

Risk response time

Risk assessment

Explanation:

The following are main variables in calculating risks:

Probability is a quantitative measure typically expressed as a numerical value between 0 and 1 or a percentage. Probability aims to precisely measure the chance of a risk event occurring based on statistical methods. Therefore, it is a main variable in calculating risks.

Likelihood is often used in qualitative analysis to describe the chance of a risk event happening subjectively. It is typically expressed using "low," "medium," and "high" or scored on a scale from 1 to 5. Therefore, it is also a main variable in calculating risks.

Risk mitigation cost is a factor considered after risks have been identified and assessed. It is not a variable used in the calculation of risk itself.

Risk response time is a factor that comes into play after a risk has occurred. It is not a variable used in the calculation of risk itself.

Risk assessment is a core component of a cybersecurity program that evaluates previously identified risks to determine their potential impact on the organization. Calculating risks is a part of that component.

q_anylz_risk_ef_01_secp8

A cybersecurity team is conducting a risk assessment of a company's IT infrastructure. The team identified a potential vulnerability that could result in the loss of a critical system.

They determined if the team does not remediate the issue, they would lose approximately 40 percent of the system's data.

What is this percentage representative of in this scenario?

Answers:

***Exposure factor (EF)**

Single loss expectancy (SLE)

Annualized loss expectancy (ALE)

Impact

Explanation:

The EF is the percentage of loss that a realized threat would have on certain assets. The cybersecurity team determined a 40% expected data loss in the scenario.

SLE is the product of the asset value and the EF. The scenario mentions only the EF (40 percent of data loss), not the overall SLE.

Calculate the ALE by multiplying SLE by the annualized rate of occurrence (ARO). The scenario does not provide information to calculate ALE.

The term impact in a risk assessment context typically refers to the consequences or effects of a risk if it occurs, not the percentage of loss, which is the exposure factor.

q_anylz_risk_ef_02_secp8

A company wants to determine the single loss expectancy (SLE) for a critical server.

What formula will the company use to calculate the SLE?

Answers:

***Asset x exposure factor (EF)**

Asset x annualized rate of occurrence

Annualized loss expectancy (ALE) x exposure factor (EF)

Annualized loss expectancy (ALE) x annualized rate of occurrence

Explanation:

The SLE is the amount a company would lose in a single risk factor occurrence. The calculation for SLE is the multiplication of the asset's value by an exposure factor (EF).

Annualized loss expectancy (ALE) is the amount a company would lose over the course of a year. The calculation for ALE is the multiplication of SLE by the annualized rate of occurrence (ARO).

To determine the ALE, the company will need to determine the SLE first. The ALE multiplied by the EF cannot determine the SLE.

The ARO calculates the ALE and cannot calculate the SLE.

q_anylz_risk_heat_map_01_secp8

A company plans to upgrade its wireless network infrastructure to improve connectivity and security. The IT team wants to ensure that the new network design provides adequate coverage, minimizes interference, and meets security standards.

To achieve this, they conduct a site survey and create a heat map of the area.

What is the primary purpose of conducting a site survey and creating a heat map for the company's wireless network upgrade?

Answers:

***To assess wireless signal coverage, identify dead zones, and optimize access point placement for the new network design.**

To identify potential security threats and vulnerabilities in the existing network.

To map out the physical layout of the building and identify potential obstacles that could affect wireless signal strength.

To evaluate the performance and bandwidth usage of the current wireless network.

Explanation:

Conducting a site survey and creating a heat map allows the IT team to assess the wireless network's coverage, identify dead zones, and optimize the placement of access points for the new network design. This process helps ensure that the new wireless infrastructure provides adequate coverage and minimizes potential connectivity issues.

The primary focus of the site survey and heat map is not on identifying security threats but on optimizing wireless signal coverage.

While mapping the physical layout is part of the process, the main purpose is to optimize coverage.

The survey is not primarily about evaluating performance and bandwidth usage but about coverage and placement optimization.

q_anylz_risk_heat_map_02_secp8

An agency needs to enhance its wireless network infrastructure to improve its overall security and connectivity. As part of the preparation, the IT Team decides to perform a site survey and develop a heat map of the site.

What is the main objective behind conducting the site survey and creating the heat map for the company's wireless network upgrade?

Answers:

***To assess wireless signal coverage, identify dead zones, and optimize access point placement for the new network design.**

To identify potential security threats and vulnerabilities in the existing network.

To map out the physical layout of the building and identify potential obstacles that could affect wireless signal strength.

To evaluate the performance and bandwidth usage of the current wireless network.

Explanation:

Conducting a site survey and creating a heat map allows the IT team to assess the wireless network's coverage, identify dead zones, and optimize the placement of access points for the new network design. This process helps ensure that the new wireless infrastructure provides adequate coverage and minimizes potential connectivity issues.

The primary focus of the site survey and heat map is not on identifying security threats but on optimizing wireless signal coverage.

While mapping the physical layout is part of the process, the main purpose is to optimize coverage.

The survey is not primarily about evaluating performance and bandwidth usage but about coverage and placement optimization.

q_anylz_risk_kri_01_secp8

A risk manager at a large corporation conducts a risk and control self-assessment (RCSA) to identify and assess risks for a new market expansion.

The manager identifies risks associated with new regulatory requirements, market volatility, and aggressive competitors.

Which key risk indicator (KRI) metric is MOST critical for managing these risks?

Answers:

The number of new customers acquired in the new market.

***The number of regulatory violations reported by the regulatory authority.**

The level of market volatility.

The frequency of security incidents involving sensitive customer data.

Explanation:

The most critical metric is the number of reported regulatory violations. The risk manager must prioritize ensuring regulatory compliance in a new market. Non-compliance can result in fines, damage to reputation, and operational disruption.

While important for business growth, customer acquisition does not directly measure risk exposure.

The company cannot directly control market volatility, an external factor. Instead, the company should develop strategies to manage the effects of volatility.

Security incidents pose significant risks, but regulatory compliance is the more immediate concern during expansion. The risk manager should manage security risks, but in this context, the focus should be on regulatory risks.

q_anylz_risk_kri_02_secp8

A company conducts a risk analysis on a newly developed software application and has identified various potential threats and their impacts.

Now, they want to set some measurable metrics that will help them understand when they might be approaching an unacceptable level of risk.

What is the company looking to define in this situation?

Answers:

***Key risk indicators (KRIs)**

Risk threshold

Risk tolerance

Risk appetite

Explanation:

Organizations use KRIs as measurable metrics to provide an early signal of increasing risk exposures in various areas of the enterprise.

While risk thresholds involve levels of risk that are acceptable to an organization, they do not involve using measurable metrics that provide an early warning of risk.

Risk tolerance is an important concept in risk management, although it doesn't involve defining measurable metrics to understand risk levels.

Risk appetite is the acceptable level of risk an organization will accept in pursuit of its objectives before action is necessary to reduce the risk. However, it does not utilize measurable metrics or indicators.

q_anylz_risk_quantitative_01_secp8

When analyzing assets, which analysis method assigns financial values to assets?

Answers:

Qualitative

***Quantitative**

Transfer

Acceptance

Explanation:

Quantitative analysis assigns a financial value or assignment of real numbers and the cost required to recover from a loss to the asset.

Qualitative analysis seeks to identify costs that cannot be concretely defined using quantitative analysis.

Transfer and acceptance are responses to risk; they are not risk analysis methods.

q_anylz_risk_quantitative_02_secp8

Which of the following does a quantitative risk assessment include? (Select the three best options.)

Answers:

***Single loss expectancy (SLE)**

***Annual rate of occurrence**

***Annual loss expectancy (ALE)**

Recovery time objective

Heat map

Risk register

Key risk indicators (KRIs)

Explanation:

A quantitative risk assessment includes:

The single loss expectancy (SLE) representing the cost of any single item loss. It is both its own formula and used to calculate ALE.

The annual rate of occurrence (ARO) indicating the number of times the loss will occur within a year. It is both its own formula and used to calculate ALE.

The annual loss expectancy (ALE) which is the single loss expectancy (SLE) times the annual rate of occurrence (ARO). ALE is the main purpose of the quantitative risk assessment.

The following are not included in a quantitative risk assessment:

The recovery time objective (RTO) which identifies the maximum time it takes to recover a system when an outage occurs.

A heat map is a simple approach to measuring inherent risk. For each risk, a simple red, yellow, or green indicator can be put into each column to represent the severity of the risk, its likelihood, cost of controls, and so on.

A risk register is a document showing the results of risk assessments in a comprehensible format and includes information regarding risks, their severity, the associated owner of the risk, and all identified mitigation strategies.

Key risk indicators (KRIs) are critical predictive indicators organizations use to monitor and predict potential risks.

q_anylz_risk_register_01_secp8

After reading an article online, a concerned business stakeholder wishes to discuss the risk associated with denial-of-service (DoS) attacks.

The stakeholder requests information about the possibilities of an attacker learning about the countermeasures in place.

Where would the security analyst look to find this information?

Answers:

***Risk register**

Risk heat map

Risk regulations

Risk and control assessment (RCA)

Explanation:

The risk register shows risk assessment results in a comprehensible format. Information in the register includes impact, likelihood ratings, date of identification, description, countermeasures, owner/route for escalation, and status.

The risk heat map is a graphical table indicating the likelihood and impact of risk factors identified. The heat map alone does not include countermeasures.

Regulations affect risk posture but do not include specifics related to specific risks or a company. Regulations include requirements to deploy security controls and make demonstrable efforts to reduce risk.

An RCA is a process that identifies risks and assesses control effectiveness intended to mitigate those risks. This process does not define countermeasures used when a company finds a risk.

q_anylz_risk_register_02_secp8

A technology firm is adopting a structured approach to managing risk. It catalogs potential risks and assigns them to responsible parties within the team. This catalog also includes the strategies to mitigate these risks and their potential impacts.

What document must the firm develop as it adopts this approach?

Answers:

***Risk register**

Risk assessment

Risk analysis

Business impact analysis

Explanation:

A risk register is a document that captures identified risks and includes their definition, the effect of their occurrence, the response strategy, and a risk owner.

Risk assessment does not inherently involve assigning responsibility for those risks to individuals or tracking them over time, a function of the risk register.

Risk analysis involves examining how project outcomes and objectives might change due to the impact of the risk event. It does not include the assignment of risk owners or the documentation of risks.

Business impact analysis involves identifying potential impacts and their effects; it does not inherently involve assigning responsibility for those impacts to individuals or tracking them over time.

q_anylz_risk_register_03_secp8

An information security officer creates a document that identifies downtime, the likelihood of occurrence, the probable impact of the downtime, and steps to mitigate the downtime and scores the likelihood based on defined security controls.

What is the information security officer creating in this instance?

Answers:

***Risk register**

Supply chain assessment

Vulnerability assessment

Supply chain analysis

Explanation:

A risk register is a repository for documenting risks identified in an organization and includes information and steps to take regarding the risk. Common information found in a risk register is the specific risk, the likelihood of occurrence, and the action.

A supply chain assessment evaluates all elements required to produce and distribute a product. The goal of a supply chain assessment is to identify areas where a company can improve.

A vulnerability assessment identifies and provides mitigation for system vulnerabilities in a company.

Supply chain analysis evaluates the risks and vulnerabilities associated with the various entities (vendors) involved in a supply chain by examining the security practices, capabilities, and reliability of individual vendors within the supply chain network.

q_anylz_risk_reporting_secp8

What is the primary purpose of risk reporting in an organization?

Answers:

***To inform stakeholders about the current risk status.**

To assign blame for risks that have occurred.

To predict future risks with 100% accuracy.

To eliminate all risks in the organization.

Explanation:

The primary purpose of risk reporting is to inform stakeholders about the current risk status. It provides an overview of the identified risks, their potential impact, and the measures taken to mitigate them. This allows stakeholders to make informed decisions about risk management.

Assigning blame for risks that have occurred is not the purpose of risk reporting. Risk reporting is a proactive process aimed at managing risks, not a reactive process for blaming individuals or teams when risks occur.

While risk reporting can help in predicting potential future risks, it cannot do so with 100% accuracy. Risk prediction involves a degree of uncertainty and the goal is to estimate potential risks based on available data, not to predict them with absolute certainty.

The goal of risk reporting is not to eliminate all risks in the organization, as this is practically impossible. Instead, it aims to manage risks effectively by identifying them, assessing their potential impact, and taking appropriate measures to mitigate them.

q_anylz_risk_sle_01_secp8

Which of the following BEST defines single loss expectancy (SLE)?

Answers:

The statistical probability of a malicious event.

The monetary value of a single employee's loss of productivity due to a successful attack.

***The total monetary loss associated with a single occurrence of a threat.**

The total cost of all countermeasures associated with protecting against a given vulnerability.

Explanation:

Single loss expectancy (SLE) is best defined as the total monetary loss associated with a single occurrence of a threat. The key to this definition is the term total. In other words, this encompasses all costs, including lost employee productivity, replacement hardware/software, and payroll for additional consultants. All of this must be considered when calculating the total loss.

Probability is a quantitative measure typically expressed as a numerical value between 0 and 1 or a percentage. Probability aims to precisely measure the statistical probability of a malicious event occurring.

The monetary value of a single employee's loss of productivity due to a successful attack is simply a statistic that is often included in risk reporting.

Inherent risk includes accounting for security controls or countermeasures that could be introduced to address every risk factor.

q_anylz_risk_sle_02_secp8

You have conducted a risk analysis to protect a key company asset. You identify the following values:

Asset value = 400

Exposure factor = 75

Annualized rate of occurrence = .25

What is the single loss expectancy (SLE)?

Answers:

100

***300**

475

30000

Explanation:

The single loss expectancy (SLE) is the asset value (AV) multiplied by the exposure factor (EF), with the EF being a percentage of the asset value that is lost. In this example, SLE = 400 x 75% = 300.

q_anylz_risk_sle_03_secp8

A tech start-up company considers deploying a new email system. The start-up is currently identifying risks associated with the potential downtime of the new system and considers the costs for each event.

What metric should the company utilize during this process?

Answers:

***Single loss expectancy (SLE)**

Annualized rate of occurrence (ARO)

Annualized loss expectancy (ALE)

Risk identification

Explanation:

Single loss expectancy (SLE) is a monetary value assigned to a single event representing the company's potential loss amount if a specific threat occurred.

The annualized rate of occurrence (ARO) refers to the estimated frequency where an expected threat will occur within a year. It does not reflect a monetary loss from a single event.

Annualized loss expectancy (ALE) is the potential yearly cost of all instances of a specific threat, calculated by multiplying the SLE with the ARO.

While risk identification is a key aspect of risk management and is the process of finding, recognizing, and describing risks, it does not refer to estimating the financial loss from a single event.

q_anylz_risk_sle_04_secp8

A newly established software firm plans to roll out a proprietary messaging platform. One of their main concerns is estimating the platform's monetary impact per incident of downtime.

What measure should the firm employ to address this concern?

Answers:

***Single loss expectancy (SLE)**

Annualized rate of occurrence (ARO)

Annualized loss expectancy (ALE)

Risk identification

Explanation:

SLE is a monetary value assigned to a single event that represents the company's potential loss amount if a specific threat occurs.

ARO refers to the estimated frequency at which a threat occurs within a year. It does not reflect a monetary loss from a single event.

ALE is the potential yearly cost of all instances of a specific threat, calculated by multiplying the SLE with the ARO.

While risk identification is an important aspect of risk management and is the process of finding, recognizing, and describing risks, it does not refer to the estimated financial loss from a single event.

q_anylz_risk_sle_ale_secp8

A tech company employs the single loss expectancy (SLE) and annualized loss expectancy (ALE) models for quantitative assessment and uses subjective judgment for qualitative analysis.

They use a heat map or traffic light impact matrix to represent the severity of the risk, its likelihood, cost of controls, etc.

What is the primary benefit of the company's approach of combining both quantitative and qualitative risk assessment methods?

Answers:

It allows for a quick initial assessment of risks and focuses on the most significant issues.

It develops tangible numbers that reflect real money and justifies the costs of various controls.

***It provides both numerical data for precision and subjective judgment for situations in which precise data is unavailable.**

It eliminates the subjectivity in risk assessment completely.

Explanation:

The company's approach employs both numerical data for precision (quantitative) and subjective judgment for situations in which precise data is unavailable (qualitative). This mixed approach provides a comprehensive understanding of the risks, their potential impact, and the likelihood of their occurrence.

While this statement accurately describes a benefit of qualitative risk analysis, it does not fully capture the advantage of combining both quantitative and qualitative methods.

This statement describes the benefit of a quantitative risk analysis approach. The combined approach of using both methods provides broader benefits.

Even though quantitative risk analysis uses numerical data for precision, the combined approach does not eliminate subjectivity completely.

q_anylz_risk_threshold_secp8

A company determines a certain level of risk that, once exceeded, requires immediate action or reconsideration of the initiative. The company takes pride in its cautious approach to business and generally avoids high-risk activities.

Which of the following should the company employ to align with its desired risk management approach?

Answers:

***Risk threshold**

Risk tolerance

Risk appetite

Risk mitigation

Explanation:

The risk threshold refers to a specific point at which risk becomes unacceptable, necessitates intervention, and the company requires immediate action or reconsideration of the initiative.

Risk tolerance refers to the degree of variability in investment returns an organization is willing to withstand. It doesn't necessarily correspond to a predetermined required point for action.

Risk appetite refers to the total exposed amount an organization wishes to undertake based on risk-return trade-offs for its business objectives.

Risk mitigation does not capture the concept of setting a defined level (threshold) beyond which risk is unacceptable.

q_biz_cont_backup_secp8

A healthcare provider is digitalizing its patient data and needs a system that guarantees the preservation of its sensitive data in the event of a disaster while avoiding lock-in to a single technology vendor's platform.

What is the MOST crucial practice the provider needs to implement?

Answers:

***Maintaining regular data backups**

Implementing an uninterruptible power supply (UPS)

Adopting platform diversity for their digital infrastructure

Incorporating additional power generators

Explanation:

Regular data backups provide a reliable way to restore data if the original becomes compromised, lost, or corrupted due to a disaster.

A UPS system ensures continuity of operations in the face of smaller-scale disruptions, like power outages, rather than handling large-scale data loss scenarios.

Platform diversity is a strategic decision about technology procurement and management rather than a specific data preservation measure.

Incorporating additional power generators maintains service availability during power disruptions. They do not preserve data integrity during a disaster or contribute to avoiding vendor lock-in.

q_biz_cont_bcp_01_secp8

What is the primary goal of business continuity planning (BCP)?

Answers:

Minimize the organization's risk of service delays and interruptions.

***Maintain business operations with reduced or restricted infrastructure capabilities or resources.**

Minimize decision-making during the development process.

Protect an organization from major computer services failure.

Explanation:

The primary goal of BCP is to maintain business operations with reduced or restricted infrastructure capabilities or resources.

Minimizing the risk of service delays and interruptions is a goal of DRP, disaster recovery plan. If your organization cannot provide services, it is experiencing a disaster. Minimizing decision making during the development process is not a valid goal of BCP or DRP; decisions should be made during development.

The correct DRP goal is to minimize decisions during an emergency.

Protecting an organization from major computer services failure is a goal of DRP, not BCP. If computer services fail, business continuity is interrupted, creating a disaster.

q_biz_cont_bcp_02_secp8

When is a BCP or DRP design and development actually completed?

Answers:

Once senior management approves

***Never**

Only after testing and drilling

Only after implementation and distribution

Explanation:

BCP (business continuity plan) and DRP (disaster recovery plan) developments are never complete as they need constant improvement and updates.

Senior management approval, testing, drilling, implementation, and distribution are all important phases and elements in the life of BCP and DRP projects. However, they do not represent the end point of BCP/DRP design and development.

q_biz_cont_bcp_03_secp8

In a recent cybersecurity meeting, the IT director emphasized prioritizing business continuity planning (BCP). The organization seeks to ensure uninterrupted business processes, especially in the wake of potential disruptions or disasters.

Which primary objective BEST captures the essence of BCP in an organization's overall security strategy?

Answers:

***Ensure that critical business processes remain operational during and after disruptions.**

Establish secure connections between office locations.

Detect and respond to any unauthorized system access.

Encrypt sensitive company data stored in databases.

Explanation:

BCP maintains the continuity of essential business functions in the face of disruptions, whether due to natural disasters, cybersecurity incidents, or other unforeseen challenges.

Although secure connections are essential for data protection and integrity, they do not represent the primary goal of BCP. This aspect is more related to secure networking and remote access policies.

Detection and response to unauthorized access are vital components of security, but they are primarily the roles of intrusion detection and response systems, not BCP.

Encryption ensures the confidentiality of data, but it is not the main focus of BCP. Data encryption is more about data at rest protection and not about business continuity.

q_biz_cont_bcp_04_secp8

A large business works with a consulting group to develop a business continuity plan. The goal of the plan is to provide a potentially uninterrupted workflow in the event of an incident.

Which one of the descriptions matches what the business is trying to achieve?

Answers:

***Ensuring processing redundancy supports the workflow**

Performing mission-critical functions without IT support

Recovery of secondary business functions when disrupted

Retention of data for a specified period

Explanation:

Business continuity planning identifies how business processes should deal with both minor and disaster-level disruption. It ensures that there is processing redundancy supporting the workflow through failover.

Organizations use continuity of operation planning (COOP) in government facilities. In some definitions, COOP refers specifically to backup methods of performing mission functions without IT support.

A disaster recovery plan is necessary when an organization's primary business function goes down. Disaster recovery requires considerable resources, such as shifting processing to a secondary site.

A retention policy is important for retrospective incident handling. A company uses the retention policy for historic logs and for how long to keep the data.

q_biz_cont_bcp_coop_secp8

During a cybersecurity seminar, the IT manager presented two significant components of their organization's continuity strategy: business continuity planning (BCP) and continuity of operations planning (COOP). The team needed clarification about the distinctive attributes of each component.

Which statement BEST distinguishes business continuity planning from continuity of operations planning in the context of an organization's overall continuity approach?

Answers:

***BCP focuses on the recovery and continuity of business functions, while COOP emphasizes maintaining essential operations during a disruption.**

BCP deals exclusively with data backups, while COOP handles physical infrastructure.

COOP is solely concerned with natural disasters, while BCP addresses cyberattacks.

BCP ensures a company's long-term profitability, while COOP only addresses short-term operational goals.

Explanation:

BCP serves to recover and ensure the continuity of business functions after a disruption. In contrast, COOP ensures that essential operations remain during the disruption itself.

Both BCP and COOP may encompass data backups and physical infrastructure. They do not exclusively handle one or the other.

Both COOP and BCP address a range of threats, including natural disasters and cyberattacks. They are not exclusive to one type of threat.

While BCP does consider long-term recovery and profitability, COOP focuses on immediate operational continuity, not just short-term goals. Both are crucial for an organization's sustainability.

q_biz_cont_capacity_planning_secp8

A prominent e-commerce company experiencing significant business growth anticipates a sharp increase in website traffic during an upcoming annual sales event. The company is wary of potential system bottlenecks or downtimes that could disrupt sales and affect reputation.

What primary strategy should the company use to ensure its systems can handle the upcoming event?

Answers:

***Rigorous capacity planning process**

Installing a uninterruptible power supply (UPS)

Implementing a failover system

Expansion of the infrastructure at the primary data center

Explanation:

The goal of capacity planning is to ensure that the system can cope with growth in demand without exceeding its capacity.

Uninterruptible power supplies (UPS) do not directly impact system performance or capacity to handle increased loads.

Failover systems ensure that services remain available during a system failure but do not contribute to the system's overall processing power or bandwidth.

Expanding the primary data center infrastructure might be part of the solution, but it is not a strategic approach to managing increased system loads, especially if the company only requires expansion at certain operation times. This would otherwise be costly.

q_biz_cont_cloud_secp8

You are the IT manager of a mid-sized company that has recently migrated its data and applications to the cloud.

A major natural disaster has just occurred, causing significant damage to your company's physical infrastructure. You need to ensure business continuity and minimize downtime.

What is the MOST appropriate action to take?

Answers:

Immediately purchase new hardware to replace the damaged infrastructure.

Rely on the cloud service provider to handle all aspects of disaster recovery.

***Initiate the disaster recovery plan that includes the use of cloud services.**

Wait for the physical infrastructure to be repaired before resuming operations.

Explanation:

Initiating the disaster recovery plan that includes the use of cloud services is the correct answer as it would ensure business continuity and minimize downtime. The cloud allows for data and applications to be accessed from anywhere, which is particularly useful in a disaster scenario where physical infrastructure may be damaged.

Immediately purchasing new hardware to replace the damaged infrastructure is not the most appropriate because the company has already migrated its data and applications to the cloud. Purchasing new hardware would be unnecessary and costly.

While the cloud service provider plays a significant role in disaster recovery, it's not advisable to rely solely on them. The company should have its own disaster recovery plan in place.

Waiting for the physical infrastructure to be repaired before resuming operations would result in significant downtime and potential loss of business. With the data and applications already in the cloud, operations can continue despite the damage to the physical infrastructure.

q_biz_cont_documentation_secp8

As the business continuity manager of a large corporation, you are reviewing the company's business continuity plan (BCP).

Which of the following elements is NOT typically included in a comprehensive BCP?

Answers:

A list of critical business functions and the resources needed to support them.

***The company's annual financial statements.**

Detailed recovery strategies and procedures.

Contact information for key personnel and stakeholders.

Explanation:

While annual financial statements are important documents within a company, they are not typically part of a business continuity plan. The BCP focuses on how to maintain and restore business operations in the event of a disruption, not on the company's financial performance.

A list of critical business functions and the resources needed to support them is a fundamental part of a BCP. It helps to prioritize recovery efforts in the event of a disruption.

Detailed recovery strategies and procedures are a crucial part of a BCP. They provide a roadmap for how to restore operations following a disruption.

Contact information for key personnel and stakeholders is typically included in a BCP. This ensures that all relevant parties can be contacted quickly in the event of a disruption.

q_biz_cont_failover_secp8

As part of the robust disaster recovery plan, a major e-commerce company is ensuring that in the event of a server failure, its customer transactions and data remain unaffected, and operations continue without any noticeable interruption.

Which of the following strategies should the company prioritize?

Answers:

***Implementing a failover mechanism**

Conducting regular tabletop exercises

Expanding the capacity of its uninterruptible power supply (UPS) systems

Increasing the frequency of its data backups

Explanation:

A failover mechanism allows for an automatic switch to a standby system upon the failure of the previously active server, ensuring uninterrupted service.

Tabletop exercises affect disaster recovery techniques but do not physically prevent service interruption.

While an uninterruptible power supply (UPS) provides emergency power to a load when the input power source fails, it does not ensure the continuity of service in the event of server failure.

Regular data backups are essential for data recovery, but they will not ensure continuous operation in the event of a server failure.

q_biz_cont_growth_secp8

In a recent company meeting, the network administrator discussed the upcoming growth projections for the next year. The IT team ensures that the organization's infrastructure can sustain the anticipated growth in user demand and traffic volume.

Which risk poses the MOST significant threat if the IT team fails to address the infrastructure needs for the forecasted growth adequately?

Answers:

An increase in phishing attack susceptibility

Reduced efficiency of network address translation (NAT)

Lesser demand for cloud storage services

***Potential for service degradation or unavailability**

Explanation:

Without properly addressed capacity planning, the primary risk involves not being able to handle the increased demand, leading to service degradation or even complete unavailability.

While security measures are crucial, capacity planning primarily focuses on scalability and performance. Phishing susceptibility is not directly related to capacity planning.

NAT efficiency is more related to routing and addressing. While capacity can impact every aspect of IT, NAT is not the primary concern related to capacity planning.

The demand for cloud storage services focuses on data needs rather than directly tied to capacity planning related to user demand and traffic volume.

q_biz_cont_hot_site_secp8

A company wants to guarantee business continuity even if a catastrophic event occurs at its primary data center.

What are the MOST appropriate strategies for the company to adopt? (Select two.)

Answers:

***Deploy a hot site**

***Disperse locations geographically**

Deploy a warm site

Utilize multicloud systems

Implement capacity planning

Explanation:

The following are the most appropriate strategies for the company to adopt:

A hot site is a real-time replica of the primary system, providing immediate failover capability. If the main system fails, the hot site instantly takes over, minimizing downtime and ensuring uninterrupted business operations.

Geographic dispersion offers protection against region-specific threats, mitigating risks and enhancing uninterrupted service.

A warm site is a more cost-effective disaster recovery option than a hot site but requires time to become operational after a failure.

Multi-cloud strategies use multiple cloud providers to enhance resilience and flexibility. However, they do not provide an immediate backup for physical data centers.

Capacity planning is a critical process in which organizations assess their current and future resource requirements to ensure they can efficiently meet their business objectives. However, it is not a business continuity factor when a catastrophic event occurs at its primary data center.

q_biz_cont_irp_secp8

During an incident response, a company discovers several problems with its incident response plan (IRP), including the communication plan being incomplete, information missing, and have assigned people that are no longer employed with the company.

What can the company do BEST to mitigate these problems from occurring? (Select the three best options.)

Answers:

***Conduct a tabletop exercise**

***Create a simulation**

***Initiate a walkthrough**

Review IRP after incidents

Review capacity planning

Improve continuity of operations

Add storage space for backups

Explanation:

The following are steps the company can take to mitigate these problems from occurring again:

A tabletop exercise involves gathering required personnel to talk through steps they would take when responding to incidents. After the completion of the exercise, the organization updates the IRP.

A simulation is an exercise where red team attempts an intrusion, blue team operates response and recovery controls, and white team moderates the exercise. They are an excellent way to test the IRP.

A walkthrough presents a scenario to responders to demonstrate actions they would complete. It involves scans and actions executed on a sandbox of the company's actual response tools.

Only reviewing the IRP after incidents will not allow the company to make changes when personnel move positions, or they add new software.

Capacity planning is a critical process in which organizations assess their current and future resource requirements to ensure they can efficiently meet their business objectives. However, it is not a part of incident response.

Continuity of operations (COOP) refers to the process of ensuring that an organization can maintain or quickly resume its critical functions in the event of a disruption, disaster, or crisis. While this process may help with an incident response, it is not a primary or best action to take.

While backups and storage space play a critical role in the continuity of operations by safeguarding against data loss and restoring systems and data in the event of disruptions, increasing storage space is not a best step to take to improve the IRP.

q_biz_cont_mission_secp8

When recovering from a disaster, which services should you stabilize first?

Answers:

Least business-critical services

***Mission-critical services**

Financial support

Outside communications

Explanation:

The services you should restore first are mission-critical services. If mission-critical services are not restored within their maximum tolerable downtime, the organization is no longer viable.

Least business-critical services should be restored last.

Financial support and outside communications should be restored only after all other services with a higher level of criticality are restored.

q_biz_cont_regulations_secp8

A multinational corporation operates in several countries with diverse regulations regarding data privacy and security.

What is the primary responsibility of the security team concerning the multitude of governmental and regulatory entities influencing the corporation's operations?

Answers:

***Ensuring compliance with all applicable regulations and laws.**

Lobbying governmental entities for favorable policies.

Avoiding any interaction with regulatory entities to maintain operational secrets.

Shaping internal policies independently from external regulations.

Explanation:

The security team's obligation is to ensure that the corporation complies with all relevant laws and regulations. Compliance is a key part of cybersecurity, particularly for multinational corporations, which can be subject to a multitude of regulations depending on their operational jurisdictions.

Lobbying governmental entities for favorable policies is typically a role for legal or government relations teams, not the security team.

Avoiding any interaction with regulatory entities to maintain operational secrets is incorrect because regulatory compliance often necessitates communication and cooperation with regulatory entities.

Shaping internal policies independently from external regulations is also incorrect because the security team must align internal policies with external regulations to maintain compliance and avoid penalties.

q_biz_cont_remote_work_secp8

In the context of a global manufacturing firm transitioning to a remote work arrangement due to a crisis, which aspect is the MOST critical to ensure business continuity?

Answers:

Identifying potential bottlenecks through regular trend analysis.

Maintaining the aesthetic value of their digital platforms.

Replacing employees unable to adapt to remote work.

***Developing robust remote work plans with appropriate technologies.**

Explanation:

Establishing robust remote work plans is crucial to ensure business continuity in a crisis when physical presence at work is impossible.

While regular trend analysis is an essential part of capacity planning to identify patterns and potential problems, the most critical step in a crisis would be to ensure that robust remote work plans are in place.

Maintaining the aesthetic value of its digital platforms, while important for user experience and branding, is not the most critical aspect in ensuring business continuity during a crisis.

Hiring new employees to replace those unable to adapt to remote work is not only time-consuming but also a costly endeavor that may not be feasible or practical in a crisis.

q_biz_cont_resilience_recovery_secp8

A lead architect is designing a new security system for a multinational corporation. The chief executive officer (CEO) emphasizes that the continuity of business operations is a top priority.

Why would incorporating resilience and recovery into the security architecture be vital in this scenario?

Answers:

It increases system efficiency.

It reduces system costs.

***It ensures system functionality during and after disruptions.**

It enhances system aesthetics.

Explanation:

Resilience implies that systems, applications, and services can recover quickly and continue operating even under adverse conditions like cyber-attacks or equipment failures. Recovery ensures the organization has strategies and measures to restore systems, applications, data, and services after a disruption.

While system performance and efficiency are important considerations, they do not directly relate to business continuity.

While resilience and recovery might indirectly help reduce costs by minimizing downtime and potential loss of data or productivity, cost reduction is not the primary function of these elements in a security architecture.

Aesthetic value is irrelevant to security architecture. The security architecture's design focuses on functionality, security, and resilience against potential threats and disruptions.

q_biz_cont_simulation_secp8

A multinational company worries that its IT department is getting complacent regarding cybersecurity. The company begins working with an outside company to create an incident in a sandbox environment to gauge the IT department's response to a strong attack.

This situation represents what type of testing scenario?

Answers:

***Simulation**

Tabletop exercise

Walkthrough

Communication plan

Explanation:

A simulation exercise takes extensive investment and preparation but presents the most real-world scenario to test personnel against. It is the best choice to test a response to an incident.

A tabletop exercise consists of select personnel discussing what their department would do in the event of an incident. It is not the best means to gauge readiness.

A walkthrough is slightly more than a tabletop exercise. This testing scenario allows the running of actual scans and demonstrates some of the capabilities, but it is not the best option.

A communication plan is part of the incident response plan and dictates who can release information during and after an incident.

q_biz_cont_tabletop_exercise_secp8

During an annual review, a health services company's leadership aims to scrutinize its disaster response and data recovery protocols. They focus on effectiveness, hidden weaknesses, and clarity of employee roles during a disaster.

Which course of action would BEST serve these objectives?

Answers:

***Organizing tabletop exercises**

Expanding the IT department

Increasing the frequency of data backups

Installing larger uninterruptible power supply (UPS) systems

Explanation:

Tabletop exercises effectively test disaster response protocols and individual roles in a low-risk, discussion-based environment. All while allowing the company to identify potential weaknesses and improve its plans accordingly.

While having more IT personnel may enhance some aspects of disaster response, it does not guarantee a comprehensive evaluation of the protocols or individual responsibilities.

Though regular data backups are crucial for data recovery, they will not provide an evaluation of the overall disaster response protocols or clarify individual roles during a crisis.

Uninterruptible power supply (UPS) systems are important for ensuring power continuity in a crisis, but they do not contribute to evaluating the disaster response plan or understanding individual roles.

12.2 Vendor Management

As you study this section, answer the following questions:

What are three types of third-party relationships?

How does onboarding with a third-party create security risk?

What security risks should be considered on a daily or ongoing basis?

Why is it important to reevaluate security risks when offboarding?

The key terms for this section include:

Term	Definition
Due diligence	A legal principal that responsible parties have used best practice or reasonable care and have not been negligent in discharging their duties.
Conflict of interest	When an individual or organization has investments or obligations that could compromise their ability to act objectively, impartially, or in the best interest of another party.
Questionnaires	In vendor management, a structured means of obtaining consistent information, enabling more effective risk analysis and comparison.
Rules of Engagement (RoE)	A definition of how a pen test will be executed and what constraints will be in place. This provides the pen tester with guidelines to consult as they conduct their tests so that they don't have to constantly ask management for permission to do something.
Memorandum of Understanding (MOU)	Usually a preliminary or exploratory agreement to express an intent to work together that is not legally binding and does not involve the exchange of money.
Nondisclosure Agreement (NDA)	An agreement that stipulates that entities will not share confidential information, knowledge, or materials with unauthorized third parties.
Memorandum of Agreement (MOA)	Legal document forming the basis for two parties to cooperate without a formal contract (a cooperative agreement). MOAs are often used by public bodies.
Business Partnership Agreement (BPA)	Agreement by two companies to work together closely, such as the partner agreements that large IT companies set up with resellers and solution providers.
Master Service Agreement (MSA)	A contract that establishes precedence and guidelines for any business documents that are executed between two parties.
Service-level Agreement (SLA)	An agreement that sets the service requirements and expectations between a consumer and a provider.
Statement of Work (SOW)/Work Order (WO)	A document that defines the expectations for a specific business arrangement.

This section helps you prepare for the following certification exam objectives:

Exam	Objective

CompTIA Security+ SY0-701	5.1 Summarize elements of effective security governance. Procedures Onboarding/offboarding 5.3 Explain the processes associated with third-party risk assessment and management. Vendor assessment Penetration testing Right-to-audit clause Evidence of internal audits Independent assessments Supply chain analysis Vendor selection Due diligence Conflict of interest Agreement types Service-level agreement (SLA) Memorandum of agreement (MOA) Memorandum of understanding (MOU) Master service agreement (MSA) Work order (WO)/statement of work (SOW) Non-disclosure agreement (NDA) Business partners agreement (BPA) Vendor monitoring Questionnaires Rules of engagement

12.2.1 Managing Third Parties (Lesson Video)

Transcript:

It's common for one organization to work directly with a third party in a vendor, supply chain, or business partner relationship. These relationships often require the both parties' information systems to connect and integrate. Doing this exposes both network to risks. You'll want to pay careful attention to the onboarding phase, the ongoing operations phase, and the offboarding phase of this third-party relationship.

Let's take a look at the onboarding phase first. During this phase of the relationship, you'll want to sit down with individuals from the third-party organization. Compare each of your organization's security policies and infrastructure. Are the security policies for each organization similar? If there are substantial differences, you should discuss them. Do both organizations have similar incident response procedures? If there are differences, how will each party handle incident response? Are the security controls similar? Are the audit policies similar? Is the security posture of each organization compatible enough to work together, or will the integration expose vulnerabilities in one or both organizations? Finding answers to these questions helps you to identify and evaluate differences and potential risks up front.

There will always be risks, so you'll need to work with your organization's leadership to determine if the risks of this potential relationship outweigh the benefits. If so, it's okay to walk away. But if the benefits outweigh the risks, you'll want to move forward with the relationship.

After that decision is made, you need to create an interoperability agreement. This agreement is a collection of documents that identifies the key responsibilities in the relationship. The documents will specify who is going to perform key tasks, how those tasks will be measured, and how decisions will be handled, and other such information.

The first interoperability agreement document you need is a Service Level Agreement, or SLA. An SLA states what each organization in the relationship will do and at what level. It may also define how disputes will be managed, provide warranties, specify disaster recovery procedures, and specify when the agreement will be terminated.

Second, we need a Memorandum of Understanding, or MOU. An MOU provides a brief summary of the relationship. It describes which party is responsible for performing specific tasks . Basically, it says who is going to do what, and when they'll do it.

Next, we'll need a Business Partnership Agreement, or BPA. A BPA explains the rules surrounding the finances of the partnership. This could include details on how to handle contributions, withdrawals, financial reporting, and the profit and loss distribution.

Another important document is the Interconnection Security Agreement, or ISA. The ISA documents how the information systems of both organizations will connect and how they're going to share data. The ISA is more technical in nature. The SLA and the MOU define the relationship, whereas the BPA and the ISA specify how the project work is going to take place.

When onboarding is complete, you can start conducting business according to the terms of the agreement. During the ongoing operations phase, you'll want to keep any eye on several things. First, regularly verify compliance with the interoperability agreement documents. Make sure that each organization is doing what it said it would do.

In addition, conduct periodic vulnerability assessments to verify that the shared network connections have not exposed or created some type of security weakness. You should also conduct regular security audits to ensure that organizations are following the security requirements contained in the interoperability agreement.

Communication between the organizations is critical. Share the vulnerability assessment and security audit findings with everyone involved in the relationship in order to maintain risk awareness.

When the operations phase is complete and you've reached the end of your agreement, you're ready to end the relationship. This process is called offboarding. Although this is an important phase, it's probably the most neglected. During offboarding, you want to ensure that all the security doors you opened to facilitate the relationship are closed. From a technical standpoint, you'll want to reset or disable any open or shared connections that you may have with the third party. This could include VPNs, firewalls, or routers and switches that were set up to share information from your network.

In addition, disable any domain trust relationships established between the organizations. Disable any user or group accounts used by third parties to access your organization's data. Finally, reset passwords used by the third party to access applications on your network.

Leaving any of these doors open could potentially expose the information on your network. During the offboarding process, you'll also want to revisit the NDA, and you'll want to put all of your end-of-business agreements into a written format.
That's it for this lesson. In this video, we talked about managing third parties. We looked at the onboarding phase and the various documents commonly used. We talked about the ongoing operations phase of the relationship, and we discussed considerations for the offboarding phase to ensure that access to your system ends with the relationship.

12.2.2 Managing Third Parties Facts

Third-party risk assessment involves several important processes integral to effective risk management practices. These processes include vendor due diligence, risk identification and assessment, ongoing monitoring, and incident response planning. Vendor due diligence involves evaluating and selecting vendors based on their security practices, financial stability, regulatory compliance, and reputation. Risk identification and assessment include identifying potential risks associated with vendor relationships and assessing their potential impact on the organization's operations, data, and reputation. Ongoing monitoring ensures vendors maintain security controls, adhere to contractual obligations, and promptly address identified risks or vulnerabilities.

These processes are critical in risk management practices as they help organizations identify, assess, and mitigate risks associated with third-party relationships. Organizations can proactively manage and reduce risks by implementing robust third-party risk assessment processes, protecting assets, maintaining regulatory compliance, and fostering a safe and secure operational environment.

This lesson covers the following topics:

- Vendor selection
- Conflict of interest
- Vendor assessment methods
- Rules of engagement
- Legal agreements

Vendor Selection

Vendor selection practices must systematically evaluate and assess potential vendors to minimize risks associated with outsourcing or procurement. It typically includes several steps, such as identifying risk criteria, conducting due diligence , and selecting vendors based on their risk profile. Risk management practices aim to identify and mitigate risks related to financial stability, operational reliability, data security, regulatory compliance, and reputation. The goal is to select vendors who align with the organization's risk tolerance and demonstrate the capability to manage risks effectively.

Third-Party Relationships

In the modern business world, it’s very common for one organization to work directly with a third party in one of the following ways:

Vendor - A vendor is a company that sells an organization's goods or provides supplies an organization needs.

Supply chain - Supply chain relationships are collaborative relationships in which companies work together to achieve their operational objectives.

Business partner - A business partnership is an agreement between parties to operate a business together and to share its profits.

Third-Party Vendor Assessment

A third-party vendor refers to an external person or organization that provides goods, services, or technology solutions to another organization but operates independently. Third-party vendors play a significant role in business operations by offering specialized expertise, products, and services that support or enable the organization's own capabilities. Third-party vendors can range from technology, software, and cloud service providers to suppliers and contractors and collectively represent an organization's supply chain. Third-party vendors bring efficiency, cost-effectiveness, expertise, and innovation to organizations but also introduce potential risks as they may have access to sensitive data, infrastructure, or critical processes. Proper vendor assessment and continuous monitoring ensure third-party vendors adhere to security standards and regulatory compliance and fulfill their obligations to safeguard business operations from potential vulnerabilities and disruptions.

Vendor assessment is a critical component of Governance, Risk, and Compliance (GRC) frameworks and plays a pivotal role in maintaining the security of IT and business operations. Vendor assessment includes carefully evaluating third-party vendor capabilities, practices, and security measures before engaging in business partnerships or entrusting them with sensitive data and critical services. The significance of vendor assessment stems from the fact that organizations increasingly rely on external vendors for various aspects of their operations, such as technology solutions, cloud services, supply chain management, and outsourcing. By thoroughly assessing vendors, businesses can ensure that their partners adhere to established security standards, comply with regulatory requirements, and mitigate potential risks effectively. Engaging with vendors with weak security practices or inadequate risk management measures can introduce significant vulnerabilities.

A study by Ponemon Institute and Bomgar identified the following statistics:

Companies allow 89 vendors to access their networks weekly, on average.

69% of organizations have experienced a data breach due to vendor security shortcomings.

65% of respondents say it's hard to manage cybersecurity risks associated with third-party vendors.

64% of respondents said their organization focuses more on cost than security when outsourcing.

https://securitystudio.com/top-7-vendor-related-breaches-of-all-time/

Evaluating vendors is vital for businesses to adhere to regulations, as these regulations often pertain to the vendors they collaborate with. Ensuring vendors comply with applicable regulations and industry standards protects the organization from fines and other legal consequences.

Additionally, vendor assessments provide evidence of due diligence and compliance checks, which are crucial during audits and investigations. Vendor assessment also promotes transparency and accountability. Organizations gain insight into vendor security capabilities by thoroughly evaluating vendor security practices. This knowledge supports better risk assessment and vendor selection. Furthermore, vendor assessments create a framework for monitoring and reviewing vendors' performance and security practices. Continuous evaluation helps ensure that vendors maintain their commitment to security and remain aligned with the organization.

Vendor Diversity

Vendor diversity is essential for several reasons, offering benefits not only in terms of cybersecurity but also in business resilience, innovation, and competition:

Cybersecurity — Relying on a single vendor for all software and hardware solutions can create a single point of failure. The entire infrastructure may be at risk if a vulnerability is discovered in that vendor's products. Vendor

diversity introduces multiple technologies, reducing the impact of a single vulnerability and making it more difficult for attackers to exploit the entire system.

Business resilience — Vendor diversity mitigates the risk associated with vendor lock-in and ensures that an organization's operations are not solely reliant on one vendor's products or services. If a vendor stops doing business, goes bankrupt, or experiences a significant disruption, having alternatives helps maintain business continuity.

Innovation — Diverse vendors bring different perspectives, ideas, and technologies. Leveraging solutions from multiple vendors can lead to a more innovative and agile IT infrastructure, better positioning an organization to adapt to emerging trends and technologies.

Competition — Vendor diversity promotes healthy competition in the market, which can lead to better pricing, improved product features, and higher-quality customer support. By engaging multiple vendors, organizations can encourage continuous improvement and obtain better value for their investments.

Customization and flexibility — Different vendors offer unique solutions that cater to specific needs, and having a diverse vendor ecosystem allows organizations to choose the best fit for their requirements. This flexibility can result in a more tailored and effective IT infrastructure.

Risk management — Vendor diversity helps spread the risk associated with potential product or service failures, security breaches, and other issues. Organizations can better manage and mitigate risks by not trusting a single solution provider or supplier.

Compliance — In some industries, regulations or industry standards may require organizations to maintain vendor diversity to ensure compliance and reduce the risk of supply chain disruptions or security breaches.

Conflict of Interest

A conflict of interest arises when an individual or organization has competing interests or obligations that could compromise their ability to act objectively, impartially, or in the best interest of another party. When performing vendor assessments, it is vital to determine whether a vendor's interests, relationships, or affiliations may influence their ability to provide unbiased recommendations, fair pricing, or deliver services without bias. Organizations must diligently identify and address potential conflicts of interest, including scrutinizing the vendor's affiliations, relationships with competitors or stakeholders, financial interests, and any potential bias that could compromise their integrity. Some examples of conflict of interest include the following items:

Financial interests — A vendor may have a financial interest in recommending specific products or services due to partnerships, commissions, or financial incentives that bias their recommendations and lead to selecting options that may not fit the organization's needs.

Personal relationships — If a vendor has personal relationships or close ties with decision-makers within the organization, it can influence decision-making and compromise the objective evaluation of other vendors.

Competitive relationships — A vendor may have a business relationship or competitive interest with another vendor under consideration, which can lead a vendor to prioritize their own interests or partnerships over the organization's best interests.

Insider information — In cases where a vendor has access to confidential or proprietary information about other vendors or the organization's strategic plans, the vendor may use this information to gain an unfair advantage or manipulate the selection process.

Vendor Assessment Methods

Due diligence, in the context of vendor assessment and selection, refers to the comprehensive and systematic process of gathering and analyzing information about potential vendors to assess their suitability, reliability, and integrity. It involves conducting a thorough investigation and evaluation of vendors based on predetermined criteria, including financial stability, reputation, technical capabilities, security practices, regulatory compliance, and past performance.

Due diligence aims to minimize risks and support informed decisions during the vendor selection process by verifying the accuracy of vendor claims, identifying potential red flags, and ensuring alignment with the organization's needs. Through due diligence, organizations can uncover any undisclosed risks or issues, clearly understand the vendor's capabilities and limitations, and evaluate the potential impact on business operations.

Assessment Method	Description
Penetration testing	Penetration testing evaluates vendors' security posture and identifies potential vulnerabilities in their systems, networks, and applications. By conducting penetration tests on vendor infrastructure or seeking evidence that penetration tests have been performed, organizations can gain insights into the vulnerabilities that attackers could exploit, helping them understand the potential risks associated with partnering with the vendor. Penetration testing provides a comprehensive assessment of the vendor's security resilience, allowing businesses to make informed decisions about their suitability as a vendor. Penetration tests improve the vendor assessment process by validating the effectiveness of security controls, uncovering hidden weaknesses, and assisting risk management practices.
Right-to-audit clause	A right-to-audit clause is a contractual provision that grants an organization the authority to conduct audits or assessments of vendor operational practices, information systems, and security controls. The right-to-audit clause supports vendor assessment practices by allowing organizations to validate and verify the vendor's compliance with contractual obligations, security standards, and regulatory requirements. By exercising the right to audit, organizations can gain transparency into the vendor's operations, identify gaps or deficiencies, and ensure that the vendor maintains the expected level of security and compliance at all times.
Evidence of internal audits	When performing vendor due diligence, looking for evidence that the vendor has internal audit practices is crucial. Internal audit provides an independent and objective evaluation of an organization's internal controls, risk management practices, and compliance with policies and regulations. By examining the presence and effectiveness of internal audits within a vendor's operations, businesses can gain confidence in the vendor's commitment to good governance, risk management, and compliance. Evidence of internal audit demonstrates that the vendor has established mechanisms for internal oversight, periodic assessments, and continuous improvement of their processes. It demonstrates a proactive approach to risk identification and mitigation and a commitment to secure operations.
Independent assessments	Organizations often rely on independent assessments as crucial vendor selection criteria. Independent assessments involve engaging with independent experts to evaluate and verify vendor capabilities, security, and compliance practices. These assessments provide an objective and unbiased evaluation of vendor capabilities. By leveraging independent assessments, organizations can benefit from specialized knowledge and industry best practice approaches to security assessments that internal teams may not know. Leveraging independent assessments helps mitigate potential biases, ensure thorough evaluations, and support informed decision-making during the vendor selection process. Additionally, periodic reassessment of existing vendors fosters continuous improvement in the vendor's security practices.
Supply chain analysis	Supply chain refers to the interconnected network of entities involved in producing, distributing, and delivering goods or services, from raw material suppliers to manufacturers, distributors, retailers,

Assessment Method	Description
	and ultimately, the end customer. It is a complex ecosystem involving collaboration between numerous vendors at various stages. Vendors are essential in the supply chain as they provide goods, services, and expertise contributing to the final product or service. Vendors often include raw materials suppliers, manufacturers, logistics providers, and technology solution providers. Each vendor within the supply chain has its own set of capabilities, processes, and potential risks. Managing and assessing these vendors is crucial to ensure the smooth flow of materials, minimize disruptions, maintain quality standards, and uphold security and compliance requirements throughout the supply chain. Supply chain analysis evaluates the risks and vulnerabilities associated with the various entities (vendors) involved in a supply chain by examining the security practices, capabilities, and reliability of individual vendors within the supply chain network and how security issues with one vendor in the chain may compromise the security of the organization's environment. This information helps organizations identify weak links, vulnerabilities, and potential points of compromise within the supply chain so they can be addressed before they cause problems.

Performing vendor site visits offers firsthand observation and assessment of a vendor's physical facilities, operational processes, and overall risk management practices, allowing for a more comprehensive evaluation of potential risks and vulnerabilities.

Vendor Monitoring

Vendor monitoring involves continuously overseeing and evaluating vendors to ensure ongoing adherence to security standards, compliance requirements, and contractual obligations. It may include regular performance reviews, periodic assessments, and real-time monitoring of vendor activities. This proactive approach allows organizations to identify and address potential risks or issues promptly.

Questionnaires

Questionnaires gather vendor information about their security practices, controls, and risk management strategies to help organizations assess a vendor's security posture, identify vulnerabilities, and evaluate their capabilities. Questionnaires provide a structured means of obtaining consistent vendor information, enabling more effective risk analysis and comparison fairly and consistently. Questionnaires collect information about the vendor's security policies, procedures, and controls, including data protection, access management, incident response, and disaster recovery. The questionnaire may ask about a vendor's compliance with industry-specific regulations and standards, such as GDPR, HIPAA, ISO 27001, or PCI-DSS. It may also seek details about the vendor's security training and awareness programs for employees and their approach to conducting third-party security assessments and audits. Additionally, the questionnaire may explore the vendor's incident response capabilities, breach history, and insurance coverage.

The answers to vendor risk management questionnaires should be validated by requesting supporting documentation, conducting site visits or audits, performing background checks, contacting references or previous clients, and utilizing third-party verification services to ensure the accuracy and reliability of the vendor's responses.

Rules of Engagement

Rules of Engagement (RoE) define the parameters and expectations for vendor relationships. These rules outline the responsibilities, communication methods, reporting mechanisms, security requirements, and compliance obligations that vendors must adhere to. Rules of engagement establish clear guidelines for the vendor's behavior, activities, and access to sensitive information. By setting these boundaries, organizations can establish a controlled and secure environment, mitigating the potential risks associated with third-party relationships. Some important elements included in an RoE include the following:

Roles and responsibilities — Clearly define the roles and responsibilities of the vendor and client in managing risks, including specifying who is responsible for identifying, assessing, and mitigating various types of risks.

Security requirements — Outline the security standards, practices, and controls the vendor must adhere to, including provisions related to data protection, access controls, encryption, incident response, and regular security assessments.

Compliance obligations — State the regulatory and compliance obligations the vendor must meet, ensuring they align with the client's industry-specific requirements, including privacy, data security, and any other applicable legal or industry regulations.

Reporting and communication — Establish protocols for timely reporting of security incidents, breaches, or potential risks, including defining the reporting channels, frequency, and level of detail required to ensure effective risk communication and management.

Change management — Outline procedures for managing changes or updates to systems, processes, or services that could impact security and introduce new risks, including change approval processes, testing requirements, and documentation practices.

Contractual provisions — Include provisions related to indemnification, liability, insurance, and termination rights in case of security breaches or failure to meet risk management obligations. These provisions help allocate responsibilities and provide legal recourse in case of noncompliance or breaches.

Legal Agreements

Legal agreements play a vital role in supporting vendor relationships by establishing both parties' rights, responsibilities, and expectations. Legal agreements serve as the foundation for the vendor-client relationship, providing a framework for conducting business and addressing potential issues or disputes that may arise.

Initial Agreements

Different types of agreements are needed to govern vendor relationships based on the specific nature of the engagement and the services being provided. The following agreements play distinct roles in setting up vendor relationships:

Memorandum of Understanding (MOU) — a nonbinding agreement that outlines the intentions, shared goals, and general terms of cooperation between parties. MOUs serve as a preliminary step to establish a common understanding before proceeding with a more formal agreement.

Non-disclosure Agreement (NDA) — ensures the confidentiality and protection of sensitive information shared during the relationship. An NDA is a binding agreement likely to be signed alongside an MOU.

Memorandum of Agreement (MOA) — a formal agreement that defines the parties' specific terms, conditions, and responsibilities. MOAs establish a legally binding relationship covering objectives, roles, resources, and obligations. They provide a trustworthy framework for collaboration.

Business Partnership Agreement (BPA) — governs long-term strategic partnerships between organizations. BPAs encompass various objectives, including goals, financial arrangements, decision-making processes, intellectual property rights, confidentiality, and dispute resolution mechanisms. BPAs provide a means for governing collaborative and mutually beneficial relationships.

Master Service Agreement (MSA) — outlines the overall terms and conditions of a specific contract, such as provisioning cloud resources or ticketing/help desk support. An MSA includes scope, pricing, deliverables, and intellectual property rights.

Detailed Agreements

Where initial agreements establish a framework for collaboration or service provision, other agreements can be implemented to specify terms for operational detail. These help to govern vendor relationships effectively.

Service Level Agreement (SLA) — defines the specific performance metrics, quality standards, and service levels expected from the vendor.

Statement of Work (SOW)/Work Order (WO) — details a vendor project or engagement's scope, deliverables, timelines, and responsibilities. SOWs clarify the vendor's tasks, the organization's expectations, and the agreed-upon deliverables. They are crucial for managing project execution and ensuring vendor and organization alignment.

12.2.3 Practice Questions (Section Quiz)

q_man_thirdparties_bpa_01_secp8

Two organizations plan on forming a partnership to provide systems security services. Onboarding requirements for both sides include a mutual understanding of quality management processes.

Which approach BEST meets this requirement?

Answers:

***Business partnership agreement (BPA)**

Non-disclosure agreement (NDA)

Service level agreement (SLA)

Measurement systems analysis (MSA)

Explanation:

BPAs are commonly used models in IT, such as among partner agreements that large IT companies set up with resellers and solution providers.

An NDA is an agreement that provides a basis for protecting information assets. NDAs are between companies and employees, between companies and contractors, and between two companies.

An SLA is a formal agreement that lays out the detailed conditions for how the vendor conducts the service.

An MSA relates to quality management processes that use quantified analysis methods to determine the effectiveness of a system and may be part of an onboarding requirement.

q_man_thirdparties_bpa_02_secp8

A new IT security firm is partnering with an IT support company and is opening its business soon. The firm would like to be a reseller for a popular firewall.

Which of the following options allows the firm to become an authorized reseller?

Answers:

***Business partners agreement (BPA)**

Memorandum of agreement (MOA)

Memorandum of understanding (MOU)

Non-disclosure agreement (NDA)

Explanation:

A BPA is a partner agreement that large IT companies set up with resellers and solution providers.

An MOA is a formal agreement, or contract, that contains specific obligations rather than a broad understanding.

An MOU is a preliminary or exploratory agreement to express an intent to work together. MOUs tend to be relatively informal and do not act as binding contracts.

An NDA is an agreement that provides a basis for protecting information assets. NDAs are agreements between companies and employees, between companies and contractors, or between two companies.

q_man_thirdparties_discuss_differences_secp8

As a new IT manager at TechCorp, you are tasked with onboarding a third-party vendor that will provide critical IT services.

During the onboarding process, you discover that the vendor's security policies and incident response procedures are significantly different from those of TechCorp.

What should you do?

Answers:

Ignore the differences and proceed with the onboarding process.

Cancel the onboarding process immediately.

***Discuss the differences with the vendor and seek to align the policies and procedures.**

Report the vendor to the authorities for having different policies.

Explanation:

When differences in security policies and procedures are identified, the best course of action is to discuss these differences with the vendor. The goal should be to align the policies and procedures as closely as possible to ensure the security of both organizations.

Ignoring significant differences in security policies and procedures could expose TechCorp to unnecessary risks. It's important to address these differences before proceeding with the onboarding process.

While it's important to take security seriously, cancelling the onboarding process immediately doesn't allow for the possibility of resolving the differences. It's better to discuss the issues with the vendor first.

Having different security policies and procedures is not illegal, and there's no need to report the vendor to the authorities. The focus should be on working with the vendor to align the policies and procedures.

q_man_thirdparties_insider_information_secp8

You are the procurement manager in a large corporation. Your company is in the process of selecting a new software vendor.

One of the vendors in the running is a company where your cousin is a senior executive. Your cousin has shared some insider information about their upcoming product updates that could give them an edge over the competition.

What should you do?

Answers:

Use the insider information to influence the vendor selection process in favor of your cousin's company.

***Disclose the relationship and the information received to your supervisor and remove yourself from the decision-making process.**

Keep the information to yourself and continue with the vendor selection process.

Share the insider information with the other vendors to level the playing field.

Explanation:

Disclosing the relationship and the information received is the best choice as it ensures transparency and removes potential bias from the decision-making process. It is the most ethical course of action and aligns with best practices for managing conflicts of interest.

Using insider information to influence a business decision is a conflict of interest and could lead to legal consequences.

Keeping the information to yourself and continuing with the vendor selection process could lead to biased decisions and potential legal consequences.

Sharing insider information with other vendors is a breach of confidentiality and could lead to legal consequences. It also does not address the conflict of interest.

q_man_thirdparties_mou_01_secp8

You are the IT manager at TechCorp and are in the process of establishing a new partnership with a third-party vendor, VendorX, for a critical IT project.

The project involves data sharing and system integration between TechCorp and VendorX. As part of the onboarding process, you need to create an interoperability agreement (IA).

Which of the following documents should be included in the IA to specify who is going to do what, and when they will do it?

Answers:

Service level agreement (SLA)

Non-disclosure agreement (NDA)

***Memorandum of understanding (MOU)**

Blanket purchase order (BPO)

Explanation:

A memorandum of understanding (MOU) is the correct answer. An MOU provides a summary of which party in the relationship is responsible for performing specific tasks. In other words, the MOU specifies who is going to do what, and when they will do it.

A service level agreement (SLA) is important for defining the services performed by the third party and the level of performance guaranteed. However, it does not typically specify who is going to do what and when they will do it.

A non-disclosure agreement (NDA) is a contract in which the third party agrees not to share any of the information gathered during the completion of the work. While it's an important part of the IA, it does not specify who is going to do what and when they will do it.

A blanket purchase order (BPO) is an agreement with a third-party vendor to provide services on an ongoing basis. While it's a critical part of the IA, it does not specify who is going to do what and when they will do it.

q_man_thirdparties_mou_02_secp8

Two technology firms are in preliminary discussions to work together on several projects. The joint venture's goal entails providing support services to a broader customer base as an entity with shared resources.

Each firm has its own customer base, custom-branded products, and established processes.

Which of the following types of agreements BEST meets the firms' needs?

Answers:

***Memorandum of understanding (MOU)**

Memorandum of agreement (MOA)

Business partners agreement (BPA)

Non-disclosure agreement (NDA)

Explanation:

An MOU is a preliminary or exploratory agreement to express an intent to work together. MOUs tend to be relatively informal and do not act as binding contracts.

An MOA is a formal agreement or contract that contains specific obligations rather than a broad understanding.

A BPA is a type of partner agreement that large IT companies, such as Microsoft and Cisco, set up with resellers and solution providers.

An NDA is an agreement that provides a basis for protecting information assets. NDAs can exist between companies and employees, between companies and contractors, and between two companies.

q_man_thirdparties_nda_01_secp8

The IT department of a medium-sized company is in the process of finalizing agreements with various vendors. The legal team drafted the contracts to ensure proper arrangements.

The team considers three types of agreements: an NDA, a BPA, and an MOU. The IT team wants to select the MOST appropriate agreement for each vendor to ensure smooth collaboration.

Which of the following agreements protects sensitive information shared between the company and its vendors?

Answers:

***Non-disclosure agreement (NDA)**

Business partnership agreement (BPA)

Memorandum of understanding (MOU)

Memorandum of agreement (MOA)

Explanation:

The non-disclosure agreement (NDA) is a suitable agreement for protecting sensitive information shared between parties and maintaining confidentiality.

The business partnership agreement (BPA) centers on defining the terms and conditions of a partnership without a specific focus on protecting sensitive information.

Although a memorandum of understanding (MOU) outlines the intentions and expectations of parties, it does not deal specifically with information confidentiality.

A memorandum of agreement (MOA) is a formal agreement or contract that contains specific obligations rather than a broad understanding and does not emphasize maintaining confidentiality between parties.

q_man_thirdparties_nda_02_secp8

In a technology company, the IT department seeks to establish a new partnership with a cloud service provider. The IT team wants well-defined partnership terms and adequate protection of sensitive data shared between the company and the vendor.

The team is considering various agreement types to achieve this goal.

What type of agreement should the IT department consider to protect sensitive information shared between the technology company and the cloud service provider?

Answers:

***Non-disclosure agreement (NDA)**

Memorandum of understanding (MOU)

Business partnership agreement (BPA)

Service level agreement (SLA)

Explanation:

Parties ensure the confidentiality and protection of sensitive information shared through the non-disclosure agreement (NDA). NDAs establish clear guidelines on what information both parties consider confidential and outline their obligations and responsibilities in safeguarding this data.

Parties actively outline their intentions and expectations in a potential partnership or collaboration through a memorandum of understanding (MOU).

Partners actively cover various aspects of the partnership, such as roles, responsibilities, decision-making processes, and dispute resolution in a business partnership agreement (BPA).

Parties enter an active contractual agreement known as the service level agreement (SLA), which details factors like performance metrics, response times, and penalties for non-compliance.

q_man_thirdparties_nda_03_secp8

The IT department in a technology company is finalizing an agreement with a cloud service provider to host sensitive customer data. The company's legal team is drafting the contract, which includes a service level agreement (SLA) and a non-disclosure agreement (NDA).

Which of the following explanations MOST accurately demonstrates the primary purpose of including an NDA in the contract with the cloud service provider?

Answers:

***To protect the confidentiality of the company's data and proprietary information**

To specify the expected service quality and support responsiveness

To ensure compliance with industry regulations and standards

To outline the vendor's responsibilities for incident response and recovery

Explanation:

Integrating an NDA into the contract protects the company's sensitive data and unique proprietary knowledge. This agreement forms a legal foundation that keeps this information secure and prevents unauthorized entities from inadvertently or maliciously disclosing it.

In contrast to the NDA, the SLA sets out the expected level of service that we expect the vendor to deliver, including standards for uptime and the speed of support responses. This ensures that the vendor meets our high service standards.

The NDA maintains the data's confidentiality and protects it from potential breaches.

The NDA strengthens our focus on confidentiality and establishes strong data protection measures.

q_man_thirdparties_nda_04_secp8

A popular entertainment company is onboarding a new employee. The company has completed preliminary interview steps and due diligence.

Internal security is extremely important, so their human resources department is preparing documentation for the formal employment process.

In implementing the process, which solution would help limit the risk of proprietary data that an employee outside the company can use?

Answers:

***Non-disclosure agreement (NDA)**

Identity and access management (IAM)

Background check

Analysis and identification

Explanation:

When an employee or contractor signs an NDA, they confirm they will not share confidential information with a third party. Signing this type of contract legally protects internal intellectual property.

IAM refers to creating an account for the user to access the computer system with the appropriate privileges.

The background check process essentially determines that a person is who they say they are and are not concealing criminal activity, bankruptcy, or connections that would make them unsuitable or risky employees.

Analysis and identification are a part of the incident lifecycle. During this phase, the identification of a threat can occur.

q_man_thirdparties_right-to-audit_secp8

You are the chief information security officer (CISO) at a large financial institution. Your company is considering a new third-party vendor for a critical data processing service.

The vendor has a strong reputation and offers a cost-effective solution. However, during the assessment, you find that the vendor's security practices are not fully transparent.

What should you do?

Answers:

Proceed with the vendor since they are cost-effective and have a strong industry reputation.

Reject the vendor immediately due to their lack of transparency.

***Negotiate a right-to-audit clause in the contract to ensure you can assess their security practices on an ongoing basis.**

Ignore the lack of transparency since the vendor's solution is critical to your operations.

Explanation:

Negotiating a right-to-audit clause in the contract is the best choice as it allows you to assess the vendor's security practices on an ongoing basis. This ensures that the vendor maintains appropriate security controls and adheres to your company's security standards.

While cost-effectiveness and reputation are important, they should not override security concerns, especially when dealing with critical data processing services.

While rejecting the vendor immediately due to their lack of transparency might seem like a safe choice, it's not necessarily the best initial action. Rejecting the vendor immediately does not leave room for potential improvements or negotiations that could lead to a win-win situation.

Ignoring the lack of transparency could lead to significant vulnerabilities and potential breaches. This could have severe consequences for your company.

q_man_thirdparties_rules_of_engagement_secp8

You are a cybersecurity consultant hired to conduct a penetration test for a client. The client has provided you with a rules of engagement (RoE) document.

Upon reviewing the document, you notice that it does not specify the timeframes for the testing activities.

What should you do?

Answers:

Proceed with the penetration test at your convenience since the RoE does not specify timeframes.

Reject the RoE and refuse to conduct the penetration test until timeframes are specified.

***Engage the client in a discussion to clarify and agree upon the timeframes for the testing activities.**

Decide on the timeframes yourself and inform the client after you have started the penetration test.

Explanation:

Engaging the client in a discussion to clarify and agree upon the timeframes is the best choice as it ensures that both parties are on the same page. This is an essential part of the RoE and should be clearly defined before the penetration test begins.

Proceeding with the penetration test without agreed-upon timeframes could lead to disruptions in the client's operations and potential misunderstandings.

Rejecting the RoE and refusing to conduct the penetration test until timeframes are specified might seem like a safe choice, but it's not necessarily the best initial action. Rejecting the RoE immediately does not leave room for potential improvements or negotiations that could lead to a win-win situation.

Deciding on the timeframes yourself and informing the client after you have started the penetration test could lead to disruptions and potential misunderstandings. It's important to agree on the timeframes before the penetration test begins.

q_man_thirdparties_sla_01_secp8

Which of the following is defined as a contract that prescribes the technical support or business parameters a provider bestows to its client?

Answers:

Mutual aid agreement

***Service level agreement**

Final audit report

Certificate practice statement

Explanation:

A service level agreement is defined as a contract that prescribes the technical support or business parameters a provider bestows to its client.

A mutual aid agreement is an agreement between two organizations to support each other in the event of a disaster.

A final audit report is the result of an external auditor's inspection and analysis of an organization's security status.

A certificate practice statement defines the actions and promises of a certificate service authority.

q_man_thirdparties_sla_02_secp8

What is a service level agreement (SLA)?

Answers:

An agreement to support another company in the event of a disaster.

A contract with a legal entity to limit your asset-loss liability.

***A guarantee of a specific level of service.**

A contract with an ISP for a specific level of bandwidth.

Explanation:

An SLA is a guarantee of a specific level of service from a vendor. That service may be communication links, hardware, or operational services. An SLA is a form of insurance against disasters or security intrusions that may affect your organization's mission-critical business functions.

An agreement to support another company in the event of a disaster is known as a mutual aid agreement.

A contract with a legal entity to limit your asset-loss liability is an insurance policy.

A contract with an ISP for a specific level of bandwidth is a service contract.

q_man_thirdparties_sla_03_secp8

An organization is considering a hybrid cloud deployment to leverage the benefits of both private and public cloud resources.

While reviewing third-party vendors, what critical aspect should the employees consider for a secure and effective transition?

Answers:

***Establish clear service level agreements (SLAs)**

Prioritize lowest-cost vendors

Focus on data redundancy

Delegate all security management to the provider

Explanation:

Clear SLAs are vital for defining performance, availability, and support expectations. As the organization chooses the correct vendor, it must oversee the establishment and execution of service level agreements as a quality control measure.

While cost is an important factor in decision making, it should not take precedence over security considerations. Choosing a vendor based solely on cost can compromise security and compliance standards.

Although data redundancy is important in maintaining data availability and preventing data loss, it is not the only security consideration.

While third-party vendors can handle parts of the security management, the organization needs to stay involved.

q_man_thirdparties_sla_04_secp8

When performing forensic investigation in public clouds, what document would contain the right-to-audit clause and give the investigator the authority to audit files on the network?

Answers:

***Service level agreement (SLA)**

Forensic reports

Supply chain analysis

Checksums

Explanation:

An SLA is a formal agreement that lays out the detailed conditions for how the vendor will conduct the service. These could include terms and conditions for security access controls and risk evaluations, plus authentication criteria for proprietary and private data.

A digital forensics report summarizes the significant contents of digital data and the conclusions of the analysis.

Supply chain analysis evaluates the risks and vulnerabilities associated with the various entities (vendors) involved in a supply chain by examining the security practices, capabilities, and individual vendors' reliability within the supply chain network.

A checksum of two hashes can validate that the investigators did not tamper with the contents of a disk.

q_man_thirdparties_sla_05_secp8

At a technology company, the IT department is finalizing an agreement with a cloud service provider to host its sensitive customer data. The IT team has actively ensured the inclusion of a service level agreement (SLA) in the contract.

What is the primary purpose of actively including an SLA in the contract with the cloud service provider?

Answers:

***To define the level of service the cloud service provider must deliver.**

To protect the confidentiality of sensitive information shared between parties.

To outline the intentions and expectations of parties involved in a potential partnership.

To establish clear guidelines on what information is considered confidential.

Explanation:

The cloud service provider actively includes an SLA to define the level of service it must deliver, covering performance metrics, response times, and availability.

While a non-disclosure agreement (NDA) holds importance in protecting sensitive information, it is not the primary purpose of the SLA inclusion in the contract.

An SLA's primary purpose is not to outline the intentions and expectations of parties in a partnership. This is the role of a memorandum of understanding (MOU).

Establishing guidelines on confidential information is not the primary purpose of an SLA; this responsibility falls under the purview of an NDA.

q_man_thirdparties_supply_chain_analysis_secp8

You are the chief procurement officer in a multinational corporation. Your company is considering a new vendor for a critical component of your product. The vendor has a strong reputation and their product is of high quality.

However, you are aware that the vendor relies heavily on a single supplier for their raw materials.

What should you do?

Answers:

Proceed with the vendor since they have a strong reputation and their product is of high quality.

Reject the vendor immediately due to their dependency on a single supplier.

***Conduct a thorough supply chain analysis to assess the potential risks associated with the vendor's dependency on a single supplier.**

Negotiate lower prices with the vendor due to their dependency on a single supplier.

Explanation:

Conducting a thorough supply chain analysis is the best choice as it allows you to assess the potential risks associated with the vendor's dependency on a single supplier. This could include assessing the supplier's reliability, financial stability, and contingency plans. This information will help you make an informed decision.

While the vendor's reputation and product quality are important, they should not override potential supply chain risks, especially when dealing with critical components.

While rejecting the vendor immediately due to their dependency on a single supplier might seem like a safe choice, it's not necessarily the best initial action. Rejecting the vendor immediately does not leave room for potential improvements or negotiations that could lead to a win-win situation.

Negotiating lower prices does not address the potential supply chain risks. If the supplier fails to deliver, it could disrupt the vendor's operations and, in turn, your own.

q_man_thirdparties_vendor_assessment_secp8

As a cybersecurity manager, you are tasked with assessing a new third-party vendor that your company is considering for a critical software solution.

The vendor has a strong reputation in the industry and offers a cost-effective solution. However, during the assessment, you find that the vendor's security practices do not fully align with your company's security standards.

What should you do?

Answers:

Proceed with the vendor since they are cost-effective and have a strong industry reputation.

Reject the vendor immediately and look for other options.

***Engage the vendor in a discussion about your security concerns and see if they are willing to improve their practices.**

Ignore the security concerns since the vendor's solution is critical to your operations.

Explanation:

Engaging the vendor in a discussion about the security concerns is the best choice as it shows due diligence and opens the door for potential improvements. If the vendor is willing to align their practices with your security standards, it could lead to a beneficial partnership.

While cost-effectiveness and reputation are important, they should not override security concerns, especially when dealing with critical software solutions. This could expose the company to significant risks.

Rejecting the vendor immediately and looking for other options might seem like a safe choice, but it's not necessarily the best initial action. Rejecting the vendor immediately does not leave room for potential improvements or negotiations that could lead to a win-win situation.

Ignoring security concerns, especially for a critical software solution, could lead to significant vulnerabilities and potential breaches. This could have severe consequences for the company.

q_man_thirdparties_vendor_diversity_secp8

You are the chief information officer (CIO) of a large corporation. Your company has been relying on a single vendor for its entire IT infrastructure for the past five years.

Recently, this vendor has been facing financial difficulties and there are rumors of a potential bankruptcy.

What should be your immediate course of action?

Answers:

Ignore the rumors and continue business as usual.

Immediately switch to another vendor to avoid potential disruptions.

***Start diversifying your vendor portfolio to ensure business resilience.**

Negotiate lower prices with the current vendor due to their financial difficulties.

Explanation:

Diversifying your vendor portfolio ensures business resilience is the best choice. It mitigates the risk associated with vendor lock-in and ensures that your company's operations are not solely reliant on one vendor's products or services. If a vendor stops doing business, goes bankrupt, or experiences a significant disruption, having alternatives helps maintain business continuity.

Ignoring potential risks, especially when they could affect the entire IT infrastructure of your company, is not a good practice. This could lead to significant disruptions in case the vendor goes bankrupt.

Immediately switching to another vendor to avoid potential disruptions might seem like a safe choice, but it could lead to immediate disruptions and potential compatibility issues. Switching to a new vendor without proper planning and assessment could introduce new risks.

While negotiating lower prices might seem like a good short-term solution, it does not address the potential risk of the vendor going bankrupt. This could still lead to significant disruptions in your IT infrastructure.

12.3 Audits and Assessments

As you study this section, answer the following questions:

What is an audit?

What are the different types of audits?

How do the types of audits differ from one another?

In this section, you will learn to:

Audit the Windows security log.

Configure advanced audit policies.

Audit device logs on a switch.

Enable device logs.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	4.3 Explain various activities associated with vulnerability management. Identification methods System/process audit Validation of remediation Audit 4.4 Explain security alerting and monitoring concepts and tools. Activities Log aggregation 4.5 Given a scenario, modify enterprise capabilities to enhance security. Operating system security Group Policy 4.9 Given a scenario, use data sources to support an investigation. Log data OS-specific security logs Network logs 5.1 Summarize elements of effective security governance. Policies Information security policies 5.5 Explain types and purposes of audits and assessments. Attestation Internal Compliance

	Audit committee Self-assessments External Regulatory Examinations Assessment Independent third-party audit
TestOut Security Pro	1.2 Harden Authentication 1.2.5 Configure and Link Group Policy Objects (GPO) 5.1 Implement logging and auditing 5.1.1 Configure advanced audit policy

12.3.1 Audits (Lesson Video)

Transcript:

Audits and assessments are crucial to maintaining trustworthy relationships and business operations. Audits involve evaluating an organization's processes, controls, and compliance, whereas an assessment evaluates operations such as cybersecurity, risk management, and internal controls. In this lesson, we'll look at the difference between internal and external assessments. We'll also look at penetration testing, one of the more common assessments that need to be performed.

When an audit or assessment is done, it'll be classified as either an internal or external assessment. An internal audit is performed by the organization's employees to provide an in-depth analysis of the organization's business processes. These internal audits should be performed on a regular basis and focus on the needs and priorities of the organization. External audits, on the other hand, are performed by an independent third party. An external audit ensures that the organization's practices meet industry standards and identifies any areas the internal audit might have missed. Performing internal and external audits and assessments provides a full accounting of the organization's policies and procedures and allows the organization to quickly identify and fix any shortcomings. Performing these audits and assessments fosters transparency and accountability and builds trust among stakeholders. One of the more common assessments that should be performed on a regular basis is a penetration test.

Penetration testing, also called pen testing or ethical hacking, involves hacking into a network to discover any vulnerabilities and weaknesses so they can be remediated before they're exploited by a malicious hacker. The penetration test utilizes the same techniques that a hacker would use, but the pen tester has written permission to perform the audit, and the scope of the test is clearly defined before anything is done.

A penetration test will typically consist of five steps. These include reconnaissance, scanning, vulnerability assessment, exploitation, and reporting. In the reconnaissance phase, the pen tester begins gathering information about their target. This can include gathering publicly available information, using social engineering techniques, and dumpster diving.

The second step is scanning the target. At this point, the tester is actively engaged with the target. Various tools are used to gather in-depth information about the network, such as live hosts, open ports, and more.

During the vulnerability assessment phase, the pen tester takes all the information they've gathered so far and identifies all potential vulnerabilities that may exist on the network. The pen tester then moves into the next phase and attempts to exploit the confirmed vulnerabilities.

The final step, reporting, involves compiling a detailed analysis of the organization's security systems. This includes all discovered vulnerabilities that were exploited, along with recommendations to remediate the vulnerabilities.
When defining the rules of the penetration test, the first step is to determine whether an unknown, partially known, or known test environment will be used. Let's look at the difference in each of these.
An unknown test is when an ethical hacker has no information about the target or network. This test is the best for simulating an outside attack and ignores insider threats. The major drawback to this type of test is that it takes more time and is much more expensive, mostly because a lot of time and resources must go into the reconnaissance and scanning phases.
A known test is the opposite of an unknown test. The pen tester is given full knowledge of the network, computer systems, and infrastructure. The known test environment allows a comprehensive and thorough test of the organization's security. Still, it's not very realistic, as an attacker will rarely have all the information handed over to them.
The partially known testing environment simulates an insider threat. The tester is given partial information about the network and computer systems. This can be IP configurations, email lists, computer names, or other information an insider would realistically have. This type of test requires less reconnaissance and scanning but doesn't give all the information to the pen tester.
Aside from testing network security, physical penetration testing should also be performed. In this type of test, the penetration tester attempts to gain access to restricted areas, sensitive information, or critical assets within the organization using techniques like social engineering, tailgating, lock picking, bypassing alarms or surveillance systems, and exploiting physical vulnerabilities.
Red team and blue team are other terms you'll run across. In the cybersecurity field, an offensive security team is called a red team, and a defensive security team is called a blue team. As the red team attempts to break into a system, the blue team works to keep them out.
That'll wrap up this lesson on audits and assessments. In this lesson, we first looked at the benefits of performing audits and assessments and the difference between internal and external audits. We then went over penetration testing, including the steps involved and the different types of penetration tests that can be performed.

12.3.2 Audit Facts

Audits and assessments are crucial to maintaining trustworthy operations. Audits involve systematically evaluating processes, controls, and compliance with established standards, policies, and regulations. They ensure that an organization's operations align with defined requirements, identify gaps, and provide recommendations for improvement.

On the other hand, assessments involve evaluating the effectiveness and efficiency of various aspects of an organization's operations, such as cybersecurity, risk management, and internal controls. They help identify vulnerabilities, assess risks, and provide insights for enhancing security measures. Both audits and assessments play a vital role in maintaining compliance, mitigating risks, and continuously improving an organization's overall security and operational performance.

This lesson covers the following topics:

- Attestation and assessments
- Internal and external assessments
- Internal assessments
- External assessments

Attestation and Assessments

Attestation refers to verifying and validating the accuracy, reliability, and effectiveness of security controls, systems, and processes implemented within an organization. It involves an independent and objective examination by a qualified and trusted entity, such as an auditor or assessor. Attestation is a formal declaration or confirmation that an organization's security controls and practices comply with specific standards, regulations, or best practices and provides assurance to stakeholders, such as

management, customers, business partners, and regulators, that an organization's security measures are adequate and effective in protecting sensitive information, mitigating risks, and maintaining data confidentiality, integrity, and availability.

Internal and External Assessments

Using internal and external audit and assessment methods is essential for a comprehensive and effective evaluation of an organization's systems, controls, and management processes. The organization's employees conduct internal audits and provide an in-depth assessment of the organization's business processes. Internal teams can conduct regular, focused assessments that align with the organization's needs and priorities and support continuous monitoring and improvement of internal controls, governance and risk management practices, and operational efficiency.

In contrast, independent third-party service providers conduct external audits and assessments that utilize specialized expertise and knowledge in specific domains, regulations, and industry best practices. External auditors convey an impartial and objective evaluation of business practices that is impossible to obtain using internal teams. External audits ensure that the organization's practices are measured against recognized industry standards and help identify improvement areas that internal audit teams may have missed.

Organizations can achieve several important objectives by utilizing internal and external audit and assessment methods. Using both approaches helps facilitate a balanced and comprehensive view of the organization's risk management practices, controls, and compliance efforts. Combining internal and external audits enhances the organization's risk management capabilities. Internal audits enable continuous monitoring, early detection of issues, and timely remediation, while external audits validate the organization's controls, compliance, and risk mitigation efforts.

Additionally, utilizing both internal and external methods fosters transparency and accountability. Internal audits promote a culture of self-assessment and continuous improvement within the organization, while external audits provide stakeholders with independent assurance and validation of the organization's practices. This combination helps build trust among stakeholders, including customers, business partners, regulatory bodies, and investors. An often overlooked benefit, the collaboration between internal and external auditors facilitates knowledge sharing and professional development, improving the quality of both teams' assessments. Internal auditors can learn from the expertise and best practices of external auditors, while external auditors gain a deeper understanding of the organization's operating environment and the challenges they face that often impede compliance initiatives.

Internal Assessments

Internal assessments are required for government agencies according to the NIST RMF, PCI-DSS, and others.

Approach	Description
Compliance assessment	Internal compliance assessments ensure operating practices align with laws, regulations, standards, policies, and ethical requirements. These assessments evaluate the effectiveness of internal controls, identify noncompliance or risk areas, and communicate findings to stakeholders such as risk managers.
Audit committee	Audit committees provide independent oversight and assurance regarding an organization's financial reporting, internal controls, and risk management practices. These committees are typically composed of board members independent of the organization's management team. Audit committees aim to enhance the integrity of financial statements, ensure compliance with legal and regulatory requirements, monitor the effectiveness of internal controls, oversee the external audit process, and promote transparency and accountability. Audit committees are critical in fostering confidence among shareholders, stakeholders, and the public by providing an independent and objective assessment of the organization's financial practices and contributing to sound corporate governance.

Approach	Description
Self-assessment	Self-assessments allow individuals or organizations to evaluate their performance, practices, and adherence to established criteria against predetermined metrics and measures. Self-assessments help identify strengths, weaknesses, and areas for improvement, enabling individuals or organizations to take proactive measures to enhance their effectiveness and outcomes. Self-assessments imply internal personnel with the expertise, knowledge, and understanding of the assessed area are available to complete them.

Internal assessments are required for government agencies according to the NIST RMF, PCI-DSS, and others.

External Assessments

External entities could include certified public accountants (CPAs), external auditors, consulting firms, regulatory bodies, or specialized assessment agencies. The independence of these external assessors ensures impartiality and objectivity in the evaluation process.

Approach	Description
Regulatory	Regulatory authorities or agencies perform assessments to ensure compliance with specific laws, regulations, or industry standards. Regulatory assessments evaluate whether organizations adhere to mandatory regulatory requirements and promote a culture of compliance. Regulatory assessments typically involve inspections, audits, or reviews of processes, practices, and controls to verify compliance, identify deficiencies, and enforce regulatory obligations. Regulatory assessments play a critical role in safeguarding public interests, protecting consumers, maintaining market integrity, and upholding industry standards. They help mitigate risks, ensure fair competition, and enhance transparency and accountability in regulated industries.
Examination	An external examination typically refers to an independent and formal evaluation conducted by external parties, such as auditors or regulators, to assess the accuracy, reliability, and compliance of an organization's financial statements, processes, controls, or specific aspects of its operations. External examinations focus on verifying information accuracy and ensuring compliance with applicable laws, regulations, or industry standards. Examples of external examinations include financial statement audits, regulatory compliance audits, and specific assessments of control environments.
Assessment	An external assessment generally refers to a broad evaluation conducted by external experts or consultants to assess an organization's overall performance, practices, capabilities, or specific focus areas. External assessments can encompass various elements, such as strategy, operational efficiency, risk management, cybersecurity, or compliance practices. The goal is to provide an objective and independent perspective on the organization's strengths, weaknesses, and opportunities for improvement.
Independent third-party audit	Independent third-party audits provide objective and unbiased assessments of an organization's systems, controls, processes, and compliance. The importance of independent third-party audits lies in their ability to offer an external perspective, free from any conflicts of interest or bias. Independent audits instill confidence among stakeholders, including customers, business partners, regulatory bodies, and investors, as they attest to an organization's commitment to quality, compliance, and good governance. They also help organizations demonstrate transparency, accountability, and adherence to industry standards and regulations.

External entities could include certified public accountants (CPAs), external auditors, consulting firms, regulatory bodies, or specialized assessment agencies. The independence of these external assessors ensures impartiality and objectivity in the evaluation process.

12.3.3 Auditing the Windows Security Log (Demo Video)

Transcript:

In this demonstration, we'll show you how to audit the Windows Security log, allowing you to audit security-related events on one host or across your entire Windows network.

There are two methods for auditing:
You can audit individual workstations using the local security policy. However, this method can be time-intensive and challenging to manage when auditing more than a few hosts.
Alternatively, you can use Group Policy, which we'll opt for as it's associated with the entire Windows domain. This is the method we'll demonstrate, as it's a more efficient solution. When a domain user logs in at a workstation, the audit settings for the Windows Security log will be applied to that workstation.
Let's open Group Policy Management.
This is our default domain, and here we have the Default Domain policy.
We'll right-click and go to Edit. Now, we have a Group Policy Management Editor, which we'll expand.
We'll navigate to Computer Configuration, Policies, Windows Settings, Security Settings, Local Policies, and Audit Policy.
On the right pane, you'll see audit policies, a total of nine.
For instance, if we explore Audit Account Management, we can specify auditing the management of user and group accounts, or we can audit directory service access and various other events.
Object Access allows us to audit access to files, folders, printers, registry keys, and more.
We also have Audit Policy Change, which audits changes made to local policies, including user rights or security options.
Audit Privilege Use lets us audit the use of user rights or privileges.
Audit Process Tracking, primarily used by application developers, tracks detailed program information for events like program activation, process, exit, handle duplication, etc. It's resource-intensive, so use it sparingly.
Lastly, we have Audit System Events, which logs system events such as server reboots, providing valuable information.
Among the more useful audits from a security perspective are Audit Account Logon and Audit Logon Events. By default, these policies are undefined. Let's configure some Audit Logon Event policy settings.
Let's open this up. We can audit for both success and failure, depending on your preferences and security needs.
For example, auditing failed logon attempts can help identify potential security threats like password guessing attacks.
On the other hand, auditing successful logins can be useful when investigating unauthorized access.
For our demonstration, we'll audit logon failure events by selecting Failure and deselecting Success.
Now, let's close the Group Policy Management Editor. The Default Domain policy is linked to the domain. To apply these settings, we need to generate some failed logon attempts and analyze them using Event Viewer.
We've restarted this machine to update the Group Policy settings.
Instead of rebooting, you can also use the Search box and type "GPupdate" to update Group Policy.
Before logging back in, we intentionally created some failed password attempts. Let's examine the results.
In Event Viewer, right-click and run as an administrator, expand Windows logs, and go to Security.
We can see that our policy in the Default Domain has generated several audit failures due to the failed logon attempts.
We can view details such as the account name that attempted to log in with a bad password.
By navigating through the logs, we can inspect these failed attempts. Now, let's close this window.
Before concluding this demonstration, let's explore one more feature.
Under Group Policy Management, we'll return to the Default Domain, Edit, Group Policy Management Editor, and go to Computer Configuration, Windows settings.
We'll expand and go to Security Settings, Local Policies, and Audit Policies.
While the basic audit policies offer settings for broader behaviors, advanced audit policies allow for more granular control over auditing specific security events.
For instance, we can configure audit policies for logon or logoff events. Under Security Settings, Advanced Audit Policy Configuration, and Audit Policies, we can target more specific audit events.
Let's take Account Logon as an example. We can audit both success and failure of logon events.

With the earlier audit settings, a single logon failure generated multiple messages in the Windows Security Log. By selecting specific audit options here, we can significantly reduce the volume of information generated, making it more manageable.
These advanced audit policies also allow auditing for specific events like account lockouts, which isn't possible with the earlier policies.
In summary, that's it for this demo. We discussed setting up auditing, configured logon auditing, generated and examined failed logon events in Event Viewer, and delved into the Advanced Audit Policy Configuration for more granular security event auditing.

12.3.4 Configure Advanced Audit Policy (Simulation)

Scenario

You work as the IT security administrator for a small corporate network. As part of an ongoing program to improve security, you want to implement an audit policy for all workstations. You plan to audit user logon attempts and other critical events.

In this lab, your task is to configure the following audit policy settings in WorkstationGPO:

Local Policies	Setting
Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings	**Enabled**
Audit: Shut down system immediately if unable to log security audits	**Enabled**

Event Log	Setting
Retention method for security log	***Define: Do not overwrite events (clear log manually)***

Advanced Audit Policy Configuration	Setting
Account Logon: Audit Credential Validation	**Success and Failure**
Account Management: Audit User Account Management	**Success and Failure**
Account Management: Audit Security Group Management	**Success and Failure**
Account Management: Audit Other Account Management Events	**Success and Failure**
Account Management: Audit Computer Account Management	**Success**
Detailed Tracking: Audit Process Creation	**Success**
Logon/Logoff: Audit Logon	**Success and Failure**
Logon/Logoff: Audit Logoff	**Success**

Policy Change: Audit Authentication Policy Change	**Success**
Policy Change: Audit Audit Policy Change	**Success and Failure**
Privilege Use: Audit Sensitive Privilege Use	**Success and Failure**
System: Audit System Integrity	**Success and Failure**
System: Audit Security System Extension	**Success and Failure**
System: Audit Security State Change	**Success and Failure**
System: Audit IPsec Driver	**Success and Failure**

Do not use the old audit policies located in **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Local Policies** > **Audit Policies** .

Explanation

While completing this lab, use the following WorkstationGPO settings:

Local Policies	**Setting**
Audit: Force audit policy subcategory settings (Windows Vista or later) to override audit policy category settings	**Enabled**
Audit: Shut down system immediately if unable to log security audits	**Enabled**

Event Log	**Setting**
Retention method for security log	***Define: Do not overwrite events (clear log manually)***

Advanced Audit Policy Configuration	**Setting**
Account Logon: Audit Credential Validation	**Success and Failure**
Account Management: Audit User Account Management	**Success and Failure**
Account Management: Audit Security Group Management	**Success and Failure**
Account Management: Audit Other Account Management Events	**Success and Failure**
Account Management: Audit Computer Account Management	**Success**
Detailed Tracking: Audit Process Creation	**Success**

Logon/Logoff: Audit Logon	**Success and Failure**
Logon/Logoff: Audit Logoff	**Success**
Policy Change: Audit Authentication Policy Change	**Success**
Policy Change: Audit Audit Policy Change	**Success and Failure**
Privilege Use: Audit Sensitive Privilege Use	**Success and Failure**
System: Audit System Integrity	**Success and Failure**
System: Audit Security System Extension	**Success and Failure**
System: Audit Security State Change	**Success and Failure**
System: Audit IPsec Driver	**Success and Failure**

Edit Audit Policies as follows:

Using Group Policy Management, access CorpNet.local's **Group Policy Objects** > **WorkgroupGPO.**

From Server Manager's menu bar, select **Tools** > **Group Policy Management** .

Maximize the windows for better viewing.

Expand **Forest: CorpNet.local** > **Domains** > **CorpNet.local** > **Group Policy Objects** .

Access the WorkstationGPO's Security Settings Local Policies.

Right-click **WorkstationGPO** and select **Edit** .

Maximize the windows for better viewing.

Under Computer Configuration, expand **Policies** > **Windows Settings** > **Security Settings > Local Policies** .

Modify Local Policies.

Select **Security Options** .

From the right pane, double-click the ***policy*** you want to edit.

Select **Define this policy setting** .

Select the ***policy settings*** as required.

Select **OK** .

Select **Yes** to confirm changes as necessary.

Repeat steps 3b - 3f for additional policy settings.

Modify the Event Log.

From the left pane, select **Event Log** .

From the right pane, double-click the ***policy*** you want to edit.

Select **Define this policy setting** .

Select the ***policy settings*** as required.

Select **OK** .

Modify Advanced Audit Policy Configuration.

From the left pane, expand **Advanced Audit Policy Configuration** > **Audit Policies** .

Select the audit policy category.

From the right pane, double-click the ***policy*** you want to edit.

Select **Configure the following audit events** .

Select the ***policy settings*** as required.

Select **OK** .

Repeat steps 5b–5f for additional policy settings.

12.3.5 Auditing Device Logs on a Switch (Demo Video)

Transcript:

In this demo, we'll discuss auditing device logs. and we'll use our Cisco managed switch as an example. Now, auditing device logs requires two things: First, we must enable logging so that we have log events that are being captured on the device. And second, we take the time to review or audit the logs to see what's happening. Let's see how this is done.

First, let's enable logging by clicking Administration, System Log, then Log Settings. You'll see that logging is currently enabled. This particular device has three types of logging. You can save log events in RAM, the random-access memory which will be lost after the system reboots. You can also save log events in flash memory which means that they'll be stored after the system reboots. And, finally, you can also aggregate, or compile, your logs and send them to a SYS log server.
To enable event aggregation, we enable the Syslog aggregator by checking the box and entering a time in seconds for Max Aggregation Time. Will enter 300 here, which will mean 5 minutes.
If you have a set of events that happen repeatedlyâ€”"for example, the same event keeps happening every five secondsâ€—"what will happen is the aggregator will say this event happened 15 times. Instead of seeing a separate entry for each similar event, you'll see the event happened and the number of times it happened within that aggregation period. We'll click apply to enable logging with aggregation.

You can add a remote log server, so you can view your logs from a central location. We'll click add and here you can specify the server by IP address or name, the UDP port, and have your logs sent to a certain facility. Let's click Close and go back to Log Settings.
As you'll notice there are several levels of logging on this device starting with Emergency. Let's talk about what each of these mean.
The Emergency level of severity means the system is not usable. An alert means that there's some sort of action that's needed. An event with critical severity means that the system is in a critical condition. An error means that there's an error in the system. Warning means that a system warning has occurred and a notice means that the system is functioning properly, but it just wants to let you know that something has happened. The informational level log is about device information. And then if you're having an issue with the device, you can log detailed debugging information about a particular event. As you'll notice we don't have debug information selected. But in our RAM logging , we're logging all of the other device events. Selecting a severity level causes all of those events higher to be selected as well. For example, we'll choose informational, and notice all the more critical events above it are selected, too.
We can also specify the Originator Identifier in our log messages by choosing None, or by hostname, IP address, or a description of your choice.
For flash memory logging which will be available after a system reboot, we're logging only a few top severity levels. These events are aggregating in our error log every 300 seconds, and then sent off to our defined SYS log server. Now let's take a look at some of the events in the event log.
With logging now setup and enabled, we're ready to view the logs. To see the logs, click on Status and Statistics, View Log, and then we can review both the RAM and Flash log entries. Notice there are various events by chronological order, newest on top. On this device, we see mostly notices and informational events, with an occasional warning. Keep an eye out for important messages like failed login attempts, logins from unauthorized workstations, device restarts, down links, and much more.
That's a quick summary of device log auditing. Remember to first enable logging so your device will generate events in the logs, then you need to take the time to periodically review the logs to see if there is important information there.

12.3.6 Enable Device Logs (Simulation)

Scenario

You are the IT security administrator for a small corporate network. You need to enable logging on the switch in the networking closet.

In this lab, your task is to:

Enable logging and the Syslog Aggregator.

Configure RAM Memory Logging as follows:

Emergency, Alert, and Critical: **Enable**

Error, Warning, Notice, Informational, and Debug: **Disable**

Configure Flash Memory Logging as follows:

Emergency and Alert: **Enable**

Critical, Error, Warning, Notice, Informational, and Debug: **Disable**

Copy the running configuration file to the startup configuration file using the following settings:

Source File Name: **Running configuration**

Destination File Name: **Startup configuration**

Explanation

Complete this lab as follows:

Access the Log Settings for the switch.

From the left menu, expand **Administration** > **System Log** .

Select **Log Settings** .

Enable Logging and Syslog Aggregator.

For Logging, select **Enable** .

For Syslog Aggregator, select **Enable** .

Configure RAM and Flash memory logging:

Under RAM Memory Logging *:*

Select **Emergency** , **Alert** , **and Critical** .

Clear **Error** , **Warning** , **Notice** , **Informational** , and **Debug** .

Under Flash Memory Logging:

Select **Emergency** and **Alert** .

Clear **Critical** , **Error** , **Warning** , **Notice** , **Informational** , and **Debug** .

Select **Apply** .

Save the changes.

From the top menu bar, select **Save** .

On the right, under *Source File Name* , make sure **Running configuration** is selected.

Under Copy/Save Configuration, select **Apply** .

Select **OK** .

Select **Done** .

12.3.7 Practice Questions (Section Quiz)

q_audits_attestation_secp8

You are a cybersecurity manager at a large multinational corporation. Your company has recently implemented a new security control system. You are tasked with ensuring the effectiveness and compliance of this new system.

Which of the following approaches would be the MOST effective for this task?

Answers:

Conduct an internal assessment only.

Conduct an external assessment only.

***Conduct both an internal and external assessment.**

Rely on self-assessment by the team that implemented the system.

Explanation:

Conducting both an internal and external assessment would be the most effective approach as it would provide a comprehensive evaluation of the new security control system. The internal assessment would align with the organization's needs and priorities, while the external assessment would provide an impartial and objective evaluation. This approach would also foster transparency and accountability, and facilitate knowledge sharing and professional development.

Conducting an internal assessment only would provide an in-depth evaluation of the organization's business processes. However, it may lack the objectivity and specialized expertise that an external assessment can provide. Therefore, this is not the most effective approach.

Conducting an external assessment only would provide an impartial and objective evaluation of the new security control system. However, it may not be as aligned with the organization's needs and priorities as an internal assessment would be. Therefore, this is not the most effective approach.

Relying on self-assessment by the team that implemented the system may not provide an objective evaluation of the new security control system. It may also lack the specialized expertise that an external assessment can provide. Therefore, this is not the most effective approach.

q_audits_auditing_secp8

Which of the following terms identifies the process of reviewing log files for suspicious activity and threshold compliance?

Answers:

Scanning

CompSec

***Auditing**

Phishing

Explanation:

Auditing is a complement to penetration testing and serves as documentation of attempted attacks that exceed preconfigured thresholds. Most operating systems, network devices, and security packages support the logging of usage data. Examples include

the success or failure of login attempts, file access, and administrative tasks. The detailed configuration of audit logs is necessary to ensure that all pertinent data is captured and available for review. Audit logs are sometimes used as evidence in court proceedings.

The following terms are not directly associated with the process of auditing:

Scanning is a term that describes digitizing an image, allowing it to be stored, modified, or understood by a computer.

CompSec is a company dedicated to solving complex IT problems.

Phishing is a type of social engineering attack often used to steal user data, including login credentials and credit card numbers.

q_audits_committee_secp8

A healthcare organization is developing its data privacy and security strategy. The leadership team is exploring different methods to monitor, evaluate, and improve security practices to ensure compliance with the Health Insurance Portability and Accountability Act (HIPAA).

What would be the MOST appropriate measure to maintain and oversee its privacy and security controls?

Answers:

***Establishing an audit committee**

Conducting a self-assessment

Implementing a security awareness program

Outsourcing security operations to a managed security service provider

Explanation:

Audit committees provide independent oversight and assurance regarding an organization's practices related to internal controls, risk management, and compliance.

Conducting a self-assessment can be a valuable tool for identifying strengths, weaknesses, and areas for improvement. Still, it provides a different level of independent oversight and continuity than an audit committee offers.

Implementing a security awareness program can help employees understand their role in maintaining data privacy and security. However, it does not provide the systematic oversight, review, and guidance on security practices that an audit committee offers.

Outsourcing security operations to a managed security service provider can help with the daily management and monitoring of security systems. However, the organization must still maintain its oversight and management capabilities.

q_audits_compliance_assessment_secp8

An organization must ensure its operating practices align with laws, regulations, standards, policies, and ethical requirements. The organization wants to evaluate the effectiveness of internal controls, identify any noncompliance or risk areas, and communicate findings to internal stakeholders such as risk managers.

Which internal assessment approach would be MOST appropriate for this purpose?

Answers:

Using an audit committee

***Compliance assessment**

Self-assessment

Regulatory assessment

Explanation:

A compliance assessment ensures that operating practices align with laws, regulations, standards, policies, and ethical requirements through an internal evaluation. This approach is the most appropriate for the scenario described.

While an audit committee may participate in the compliance process, it does not specifically evaluate compliance with laws and regulations.

A self-assessment, which can serve various purposes, including compliance, does not specifically evaluate compliance with laws and regulations.

External regulatory authorities or agencies typically perform a regulatory assessment to ensure compliance with specific laws, regulations, or industry standards, not as an internal assessment approach.

q_audits_external_assessment_secp8

An organization must hire nonaffiliated experts (consultants) to conduct an assessment. The organization expects the experts to provide a broad evaluation of their overall performance, practices, and capabilities, including specific focus areas, such as strategy, operational efficiency, risk management, cybersecurity, or compliance practices.

Which type of assessment meets the organization's needs?

Answers:

Self-assessment

Internal compliance assessment

***External assessment**

Internal audit committee

Explanation:

External experts or consultants conduct an external assessment to evaluate an organization's overall performance, practices, capabilities, or specific focus areas.

Individuals or organizations conduct self-assessments internally to evaluate their performance, practices, and adherence to established criteria against predetermined metrics and measures without the involvement of external experts.

An organization conducts an internal compliance assessment to ensure that its operating practices align with laws, regulations, standards, policies, and ethical requirements without involving external experts.

The internal audit committee provides independent oversight and assurance regarding an organization's financial reporting, internal controls, and risk management practices without involving external experts.

q_audits_external_examiniation_secp8

A multinational corporation wants to enhance its risk management procedures and validate that its systems, controls, and processes align with specific international standards, regulations, and best practices.

Which approach should the organization consider to ensure an unbiased and comprehensive analysis of its security posture?

Answers:

***External examination**

Self-assessment

Internal compliance assessment

Internal audit

Explanation:

External (unbiased) examination ensures a thorough assessment of the organization's compliance with international standards and best practices.

Self-assessment allows an organization to evaluate its performance, practices, and adherence to established criteria. While it can be helpful, self-assessment does not provide the independent and comprehensive review of an organization's security posture that an external examination would.

Internal compliance assessment, being an internal process, may not provide as comprehensive and unbiased an evaluation as an external examination.

An internal audit may offer a different level of objectivity and comprehensive assessment than an external examination can provide.

q_audits_external_secp8

Which type of audit is performed by either a consultant or an auditing firm employee?

Answers:

Internal audit

Usage audit

***External audit**

Financial audit

Explanation:

An external audit is performed by either a consultant or an auditing firm employee.

Internal audits are performed by an employee within an organization. They examine existing internal controls and maps the security structure for compliance with statutes and management goals.

Usage and financial audits can be performed by either internal or external auditors, depending on the reason for the audit.

q_audits_internal_01_secp8

Which of the following is true concerning internal audits?

Answers:

They are always highly rigorous.

The process is very formal.

***They are generally nonobjective.**

The auditor works independently.

Explanation:

Internal audits tend to be nonobjective and, consequently, may not be as rigorous.

None of the other answers best describe internal audits.

q_audits_internal_02_secp8

After several incidents, a financial organization is taking steps to improve its cybersecurity posture.

As part of these measures, it has implemented new security controls to ensure the confidentiality and integrity of customer data.

To provide the board of directors with reliable assurance about the effectiveness of these new controls before making a public statement, what approach should the organization employ?

Answers:

***Conduct an internal security audit.**

Initiate an attestation process.

Request an external security audit.

Commence third-party attestation.

Explanation:

Conducting an internal security audit can swiftly identify if the new measures are effective and directly communicate the findings to the board.

Initiating an attestation process offers a substantial degree of assurance, although it needs to address the board's need to understand the effectiveness of new measures from an internal perspective.

Requesting an external security audit may take more time and effort to evaluate the new measures than an internal audit. Additionally, the board requires assurance based on an internal evaluation.

Third-party attestation can offer high assurance, although it may offer a different, internally-focused assurance than the board seeks about the new security measures.

q_audits_pci_secp8

Which of the following standards relates to the use of credit cards?

Answers:

SOX

PoLP

***PCI DSS**

Financial audit

Explanation:

Personal Card Industry Data Security Standard (PCI DSS) compliance audits relate to the use of credit cards. These audits are regulated and enforced by major credit card companies.

A Sarbanes-Oxley (SOX) audit is a government audit by the SEC that relates to internal controls and focuses on IT security, access controls, data backup, change management, and physical security.

PoLP is the principle of least privilege. It does not apply in this scenario.

Financial audits are performed to ensure compliance with SOX or PCI DSS requirements.

q_audits_third_party_secp8

An organization validates its security controls, processes, and adherence to industry standards and wants an unbiased evaluation to instill confidence among stakeholders.

Which method should it employ for this purpose?

Answers:

Compliance assessment

Audit committee

Self-assessment

***Independent third-party audit**

Explanation:

An independent third-party audit offers an external, objective, and unbiased assessment of an organization's systems, controls, processes, and compliance. The goal is to instill confidence among stakeholders, including customers, business partners, regulatory bodies, and investors.

While compliance assessments help ensure that the organization's practices align with laws, regulations, standards, and policies, the company typically conducts them internally, making bias possible.

Although audit committees provide independent oversight and assurance regarding the organization's financial reporting, internal controls, and risk management practices, the organization's board members usually form the committees.

While self-assessments can be valuable for identifying improvement areas, they do not provide an external, unbiased perspective.

13.0 Data Protection and Compliance

13.1 Data Classification and Compliance

As you study this section, answer the following questions:

What is the purpose of classifying data?

What is the difference between PII and PHI?

Why is it important to know data destruction types?

How are privacy enhancing technologies used to protect PII?

Key terms for this section include the following:

Term	Definition
Data breach	When confidential or private data is read, copied, or changed without authorization. Data breach events may have notification and reporting requirements.
Escalated	In the context of support procedures, incident response, and breach-reporting, escalation is the process of involving expert and senior staff to assist in problem management.
Health Insurance Portability and Accountability Act (HIPAA)	US federal law that protects the storage, reading, modification, and transmission of personal healthcare data.
Regulated data	Information that has storage and handling compliance requirements defined by national and state legislation and/or industry regulations.
Trade secret	Intellectual property that gives a company a competitive advantage but hasn't been registered with a copyright, trademark, or patent.
Legal data	Documents and records that relate to matters of law, such as contracts, property, court cases, and regulatory filings.
Financial data	Data held about bank and investment accounts, plus information such as payroll and tax returns.
Human-readable data	Information stored in a file type that human beings can access and understand using basic viewer software, such as documents, images, video, and audio.

Non-human-readable data	Information stored in a file that human beings cannot read without a specialized processor to decode the binary or complex structure.
Data classification	The process of applying confidentiality and privacy labels to information.
Proprietary information or intellectual property (IP)	Information created by an organization, typically about the products or services that it makes or provides.
Data subjects	An individual that is identified by privacy data.
Data inventories	List of classified data or information stored or processed by a system.
Data retention	The process an organization uses to maintain the existence of and control over certain data in order to comply with business policies and/or applicable laws and regulations.
Disposal/decommissioning	In asset management, the policies and procedures that govern the removal of devices and software from production networks and their subsequent disposal through sale, donation, or as waste.
Sanitization	The process of thoroughly and completely removing data from a storage medium so that file remnants cannot be recovered.
Destruction	An asset disposal technique that ensures that data remnants are rendered physically inaccessible and irrevocable through degaussing, shredding, or incineration.
Certification	An asset disposal technique that relies on a third party to use sanitization or destruction methods for data remnant removal as well as providing documentary evidence that the process is complete and successful.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	3.3 Compare and contrast concepts and strategies to protect data. Data types Regulated

- Trade secret
- Intellectual property
- Legal information
- Financial information
- Human and non-human readable

Data classifications

- Sensitive
- Confidential
- Public
- Restricted
- Private
- Critical

General data considerations

- Data sovereignty

4.2 Explain the security implications of proper hardware, software, and data asset management.

Disposal/decommissioning

- Sanitization
- Destruction
- Certification
- Data retention

5.1 Summarize elements of effective security governance.

Roles and responsibilities for systems and data

- Controllers
- Processors

5.4 Summarize elements of effective security compliance.

	Consequences of non-compliance Fines Sanctions Reputational damage Loss of license Contractual impacts Privacy Legal implications Local/regional National Global Data subject Controller vs. processor Ownership Data inventory and retention Right to be forgotten

13.1.1 Consequences of Breaches (Lesson Video)

Transcript:

All too frequently, we read about a data breach. Large companies with security budgets in the millions of dollars are not exempt. Most of us have, at onetime or another, been notified that our information has been compromised. It could be bank accounts, credit cards, government records, or even health records. All these data breaches come with serious consequences. Let's talk about what they are.

A company's reputation determines if people will invest, if consumers will buy, and if foreign governments will allow a company to do business internationally. A company lives or dies by its revenues and investments.
A breach that exposes private client data directly affects the way consumers and investors spend money. A data breach can cause stock prices to fall. Falling stock prices lead to sell offs and can permanently damage a company.
When trust is broken and consumer confidence is damaged, revenues drop because consumers stop using the company. Also, the loss of government contracts because of breach can prove fatal for a company.
Twenty years ago, the term identity theft didn't have any real meaning to the everyday person. Fast forward to today, and it is difficult to find someone who hasn't experienced identity theft on some level. When a breach occurs and personal

information is stolen, the affected person is forced to do hours, days, and even weeks of work to correct someone else's mistake. The effects of identity theft can last years and cause fear and paranoia among those affected. Lives have been turned upside down leaving victims frustrated because it is almost impossible to catch the perpetrator.

A data breach can also be financially costly. With the introduction of GDPR and the California Consumer Privacy Act the number of companies that can be fined has grown significantly. In the United States, HIPAA has always carried fines for companies found in non-compliance. Companies that profit from the use of consumer personal information can also have heavy fines levied by the Federal Trade Commission and possibly the Security and Exchange Commission.

To give you an idea of the magnitude of these fines, in 2019 three data breaches at three separate companies cost the companies over 1 billion dollars. It is estimated that fines for a single data breach now averages $6.45 million dollars.

Intellectual Property is the lifeblood of companies. When IP is stolen ,companies lose competitive advantage.

The internet has made the world smaller. Companies are now competing with others from around the globe. IP stolen through a data breach is often sold to competing companies.

Many of the overseas companies are not subject to laws in the United States. This makes it difficult to enforce IP laws. The reverse engineering or the direct copy of IP gives thieves an undeserved revenue source. IP theft also floods the market with counterfeit goods.

Let's look at an IP theft scenario. The XYZ company has worked tirelessly on a new product that's cutting-edge. As the company is going into production, they experience a data breach. They are not sure what data may have been lost. A few months later, counterfeit versions of their cutting-edge product start flooding the market. They now discover that their intellectual property was stolen during the breach. The fakes are selling for less money and destroying XYZ's profits.

Escalation can be separated into two categories, internal escalation and external escalation. Internal escalation is part of a company's incident response plan. This usually means a tiered approach to informing management of a breach. As a breach is investigated, the findings and severity will determine how far the escalation will go. The external escalation involves experts brought in from the outside to investigate, provide legal counsel, or even prosecute, which involves law enforcement. The key is to know when a situation has surpassed your abilities to resolve it.

That's it for this lesson. In this lesson, we showed you how data breaches can have serious consequences including loss of trust, fines, and theft of intellectual property. Fines are averaging $6.45 million per event. All 50 states have laws outlining the data breach notification requirements. We also looked at a scenario of IP theft and its consequences.

13.1.2 Consequences of Breaches Facts

Breaches affect all companies. This includes even large companies with security budgets in the millions of dollars. Most of us have, at one time or another, been notified that our information has been compromised. It could be bank accounts, credit cards, government records, or even health records. All these data breaches come with serious consequences.

This lesson covers the following topics:

- Impacts of non-compliance
- Privacy breaches and data breaches
- Software licensing non-compliance
- Impacts of contractual non-compliance

Impacts of Non-compliance

Security compliance refers to organizations' adherence to applicable security standards, regulations, and best practices to protect sensitive information, mitigate risks, and ensure data confidentiality, integrity, and availability. Effective compliance necessitates establishing and implementing policies, procedures, controls, and technical measures to meet the requirements set forth by regulatory bodies, industry standards, and legal obligations.

Non-compliance with data protection laws and regulations can have severe consequences for organizations. The consequences vary depending on jurisdiction and the specific regulations violated. Common ramifications for non-compliance include legal sanctions such as financial penalties, legal liabilities, reputational damage, and loss of customer trust. Sanctions refer to penalties,

disciplinary actions, or measures imposed due to non-compliance with laws, regulations, or rules. Sanctions are enforced by governing bodies, regulatory authorities, or organizations overseeing the specific domain in which the non-compliance occurred. Regulatory agencies may impose substantial fines, which can amount to millions or even billions of dollars, depending on the severity of the violation. Legal action from affected individuals or data subjects may lead to costly lawsuits and settlements. Non-compliance can harm an organization's reputation, eroding customer trust, decreasing business opportunities, and potentially losing contracts or partnerships. Organizations may also face additional regulatory scrutiny, including increased audits, investigations, or mandated remediation measures. Organizations must prioritize data protection compliance, implement appropriate security measures, conduct regular risk assessments, and stay informed about evolving data protection laws and regulations to avoid these consequences.

Privacy Breaches and Data Breaches

A data breach occurs when information is read, modified, or deleted without authorization. "Read" in this sense can mean either seen by a person or transferred to a network or storage media. A data breach is the loss of any type of data (but notably corporate information and intellectual property). In contrast, a privacy breach refers specifically to the loss or disclosure of personal and sensitive data.

Organizational Consequences

A data or privacy breach can have severe organizational consequences:

Consequences	Description
Reputation damage	Data breaches cause widespread negative publicity, and customers are less likely to trust a company that cannot secure its information assets. Consumers stop using the company, revenues drop, and possibly lost investments.
Identity theft	If the breached data is exploited to perform identity theft, the data subject may be able to sue for damages. The effects of identity theft can last for years and cause fear and paranoia among the victims. Lives have been turned upside down, leaving victims frustrated to deal with the ramifications.
Fines	Legislation might empower a regulator to levy fines. These can be a fixed sum or, in the most serious cases, a percentage of turnover. Regulations like the General Data Protection Regulation (GDPR), California Consumer Privacy Act (CCPA), Health Insurance Portability and Accountability Act (HIPAA), and many more do impose fines for non-compliance.
IP theft	Loss of company data can lead to loss of revenue. This typically occurs when copyright material—unreleased movies and music tracks—is breached. The loss of patents, designs, trade secrets, and so on to competitors or state actors can also cause commercial losses, especially in overseas markets where IP theft may be difficult to remedy through legal action.

Escalation

A breach may be detected by technical staff, and if the event is considered minor, there may be a temptation to remediate the system and take no further notification action. This could place the company in legal jeopardy. Any breach of personal data and most breaches of IP should be escalated to senior decision-makers, and any impacts from legislation and regulation properly considered.

Notifications of Breaches

The requirements for different types of breaches are set out in law and in regulations. The requirements indicate who must be notified. A data breach can mean the loss or theft of information, the accidental disclosure of information, or the loss or damage of information. Note that there are substantial risks from accidental breaches if effective procedures are not in place. If a database administrator can run a query that shows unredacted credit card numbers, that is a data breach, regardless of whether the query ever leaves the database server.

Depending on the regulations, a breach may be considered to have occurred if there is just the potential for unauthorized access. For example, if a personal data file is configured with permissions that mistakenly allow any authenticated user to read it, this could be classified as a notifiable data breach, even if audit logs show that no improper access attempts were made.

Public Notification and Disclosure

Other than the regulator, notification might need to be made to law enforcement, individuals, and third-party companies affected by the breach and the public through press or social media channels. For example, the Health Insurance Portability and Accountability Act (HIPAA) sets out reporting requirements in legislation, requiring breach notification to the affected individuals, the Secretary of the US Department of Health and Human Services, and, if more than 500 individuals are affected, to the media (hhs.gov/hipaa/for-professionals/breach-notification/index.html). The requirements also set out timescales for when these parties should be notified. For example, under GDPR, the notification must be made within 72 hours of becoming aware of a breach of personal data (csoonline.com/article/3383244/how-to-report-a-data-breach-under-gdpr.html). Regulations will also set out disclosing requirements or the information that must be provided to each of the affected parties. Disclosure is likely to include a description of what information was breached, details for the main point of contact, likely consequences arising from the breach, and measures taken to mitigate the breach.

GDPR offers stronger protections than most federal and state laws in the United States, which tend to focus on industry-specific regulations, narrower definitions of personal data, and fewer rights and protections for data subjects. The passage of the California Consumer Privacy Act (CCPA) has changed the picture for domestic US legislation, however (csoonline.com/article/3292578/california-consumer-privacy-act-what-you-need-to-know-to-be-compliant.html).

Software Licensing

Non-compliance with software licensing requirements can result in the revocation of usage rights and other consequences, such as fines. Violations of license agreements, such as exceeding permitted installations, unauthorized sharing, or other unauthorized usage, constitute contractual non-compliance. Other forms of non-compliance include breaching license terms, such as modifying code or distributing software without authorization. In response, software vendors or licensing authorities may revoke or suspend licenses and take other legal actions. The loss of software licenses can disrupt business operations, causing inefficiencies and workflow interruptions as well as cause significant reputational damage. To ensure compliance, organizations can rectify non-compliance through license remediation, proper license management, and audits.

Impacts of Contractual Non-compliance

Category	Description
Breach of contract	Non-compliance can result in a breach of contract. Contracts between parties often include provisions related to data protection, cybersecurity measures, and the safeguarding of sensitive information. Failure to meet these contractual obligations can lead to legal consequences, including potential liability for damages or loss the non-compliant party suffers.
Termination of contracts	Non-compliance may give the non-compliant party grounds for contract termination. Contractual agreements may contain clauses allowing termination if the other party fails to adequately protect data or implement sufficient cybersecurity measures . The non-compliant party may face termination penalties, loss of business relationships, and the need to seek new contractual arrangements, which will be complicated by poor past performance.

Category	Description
Indemnification and liability	Non-compliance may result in the non-compliant party assuming liability for damages caused by a security breach or data loss. Contractual agreements may include indemnification clauses, shifting responsibility for losses or legal expenses resulting from cybersecurity incidents onto the non-compliant party, leading to financial burdens and reputational damage.
Non-compliance penalties	Contracts may stipulate penalties or financial consequences for non-compliance with cybersecurity requirements, such as monetary fines or contractual damages that the n on-compliant party must pay to the aggrieved party. Non-compliance penalties aim to incentivize adherence to cybersecurity measures outlined in the contractual agreement.

13.1.3 Information Classification (Lesson Video)

Transcript:

In this video, we're going to talk about information classification. There are several types of data, and data needs to be classified and secured. First, let's go over general classifications of data.

All data falls into one of five categories. Public data is available to anyone. Private data has limited distribution. Sensitive data is for internal use. Critical data is covered by laws and compliance regulations. Proprietary data is exclusive to a particular entity. Let's look at each of these in detail.
The first information classification is Public. This classification allows anyone to have a copy of the information. Examples include a public website that everyone can access, company brochures, and marketing material. This data exists to be released.
Private data is not for general release to the public. It includes internal email addresses, company meeting notes, company presentations, and customer lists. This is information you don't want released to the public, but if it were accidentally released, damage to your organization would be light to moderate.
Sensitive data is information that, if exposed, could cause significant damage to an organization. Sensitive data is restricted even within the company that's responsible for it. It may include strategic information, customer lists, personally identifiable information (PII), and company strategies.
Critical data includes personally identifiable information, credit card data, health records, and other information covered under compliance regulations. These include The General Data Protection Regulation, or GDPR, and The California Consumer Protection Act. The disclosure of critical data will cause severe harm and financial penalties.
Proprietary information includes information that's unique and differentiates a company from its competitors. Examples are Google's search algorithm, the recipe for Coca-Cola, or patents granted for inventions and processes. The release of this information would cause serious damage, maybe even irreparable damage.
Now let's talk about very specific kinds of data that need to be classified by a company. This data is covered by laws, government regulations, and compliance acts.
The first is classified data.
Personal Identifiable Information includes almost any data that can be used to identify a person: their name, addresses, email, phone number, or even a photograph.
The Health Insurance Portability and Accountability Act (HIPAA) has many facets, but the one that concerns you most as a security administrator is their policy on Electronic Health Information, or eHI. This classification includes data related to an individual's health and information collected by doctors, health clinics, health insurance companies, and employers. It must be secured in all usage statesâ€“ at rest, in use, or in motion. The exposure, loss, or breach of this data incures significant fines from the U.S. government.
Financial data is covered by a few laws and compliance bodies. It includes consumer credit card information, bank account numbers, and corporate financial requirements.
There are also government/military classification levels. The public can view Unclassified information. The next classification is Sensitive, but Unclassified. For this classification, the government or military would prefer the information not be available to the public, but it is unclassified. Disclosure could cause harm, but the harm would be minimal.

The next level is Confidential. It allows restricted information release under the Freedom of Information Act. The level above that is Secret, and it includes troop movements, deployments, and overall capabilities. The highest classification is Top Secret. Release of Top-Secret information can pose a grave threat to the country and national security.
That's it for this lesson. In this lesson, we covered the different data classifications and examples of data in each classification: public, private, sensitive, and critical.
Then we looked at specific types of data, including PII, ePHI, credit cards, and unclassified, confidential, secret, and top-secret.

13.1.4 Information Classification Facts

The concept of data types refers to categorizing or classifying data based on its inherent characteristics, structure, and intended use. Data types provide a way to organize and understand the different data forms within a system or dataset. Classifying data into specific types makes analyzing, processing, interpreting, and securing information easier.

This lesson covers the following topics:

- Regulated data
- Trade secrets
- Legal and financial data
- Human-readable and non-human-readable data
- Data classifications

Regulated Data

Regulated data refers to specific categories of information subject to legal or regulatory requirements regarding their handling, storage, and protection. Regulated data typically includes sensitive or personally identifiable information (PII) protected by laws and regulations to ensure privacy, security, and appropriate use. The types of regulated data vary depending on jurisdiction and the specific regulations applicable to the organization or data. Common examples of regulated data include financial information, healthcare records, social security numbers, credit card details, and other personally identifiable information. Privacy laws and industry-specific regulations often protect these data types, such as the Health Insurance Portability and Accountability Act (HIPAA) for healthcare data or the Payment Card Industry Data Security Standard (PCI DSS) for credit card information. Organizations that handle regulated data must comply with relevant laws and regulations governing its protection. Compliance typically involves implementing appropriate security measures, data encryption, access controls, data breach notification procedures, and data handling protocols. Organizations may also need to establish data storage, retention, and destruction safeguards to meet regulatory requirements.

Trade Secrets

Trade secret data refers to valuable, confidential information that gives a business a competitive advantage. Trade secrets encompass much nonpublic, proprietary information, including formulas, processes, methods, techniques, customer lists, pricing information, marketing strategies, and other business-critical data. Trade secrets have commercial value derived from their secrecy. Businesses often require employees and contractors to sign non-disclosure agreements (NDAs) to safeguard the confidentiality of trade secrets. Disclosure or unauthorized use of trade secret data is a serious legal matter. Companies can take legal action against individuals or organizations unlawfully acquiring, using, or disclosing trade secrets. Laws related to trade secrets vary across jurisdictions, but they generally aim to prevent unfair competition and provide remedies for misappropriation.

Legal and Financial Data

Legal and financial data encompass critical data for legal compliance, financial reporting, decision-making, and risk management. Legal data includes documents, contracts, legal agreements, court records, litigation information, intellectual property filings, regulatory filings, and other legal documents. It may also encompass information related to corporate governance, compliance with laws and regulations, and legal obligations specific to an industry or jurisdiction. On the other hand, financial data pertains to information concerning an organization's financial activities, performance, and transactions, including financial statements, balance sheets, income statements, cash flow statements, audit reports, tax records, financial projections, budgets, and other financial reports. Financial data also encompasses details of financial transactions, such as accounts payable, accounts receivable, general ledger entries, and transactional records. Legal and financial data are highly sensitive and confidential due to their nature and the potential impact they can have on an organization's reputation, legal standing, and financial stability.

Human-Readable and Non-Human-Readable Data

Human-readable data refers to information humans can easily understand and interpret without additional processing or translation. Human-readable data describes a format that is accessible and readable, such as text, images, or multimedia content. Examples of human-readable data include documents, reports, emails, web pages, and presentations. On the other hand, non-human-readable data refers to data that is not easily understood or interpreted by humans in its raw form. It may be in a machine-readable format, such as binary code, encrypted data, or data represented in a complex structure or encoding that requires specialized software or algorithms to decipher and interpret. Non-human-readable data often requires additional processing or transformation to make it understandable to humans.

Human-readable and non-human-readable data formats have distinct implications for security operations and controls. Human-readable and non-human-readable data formats impact security operations and controls in different ways. Security monitoring, user awareness, DLP, content filtering, and web security are more directly applicable to human-readable data formats.

On the other hand, encryption, access controls, intrusion detection and prevention, secure data exchange, and code/application security are more relevant to non-human-readable data formats. It is important to note that non-human-readable data formats can impede the capabilities of security controls because non-human-readable data formats cannot be easily interpreted using traditional methods and require specialized approaches to inspect and protect them. A comprehensive security approach considers both types of data formats and implements appropriate measures to protect them based on their characteristics and associated risks.

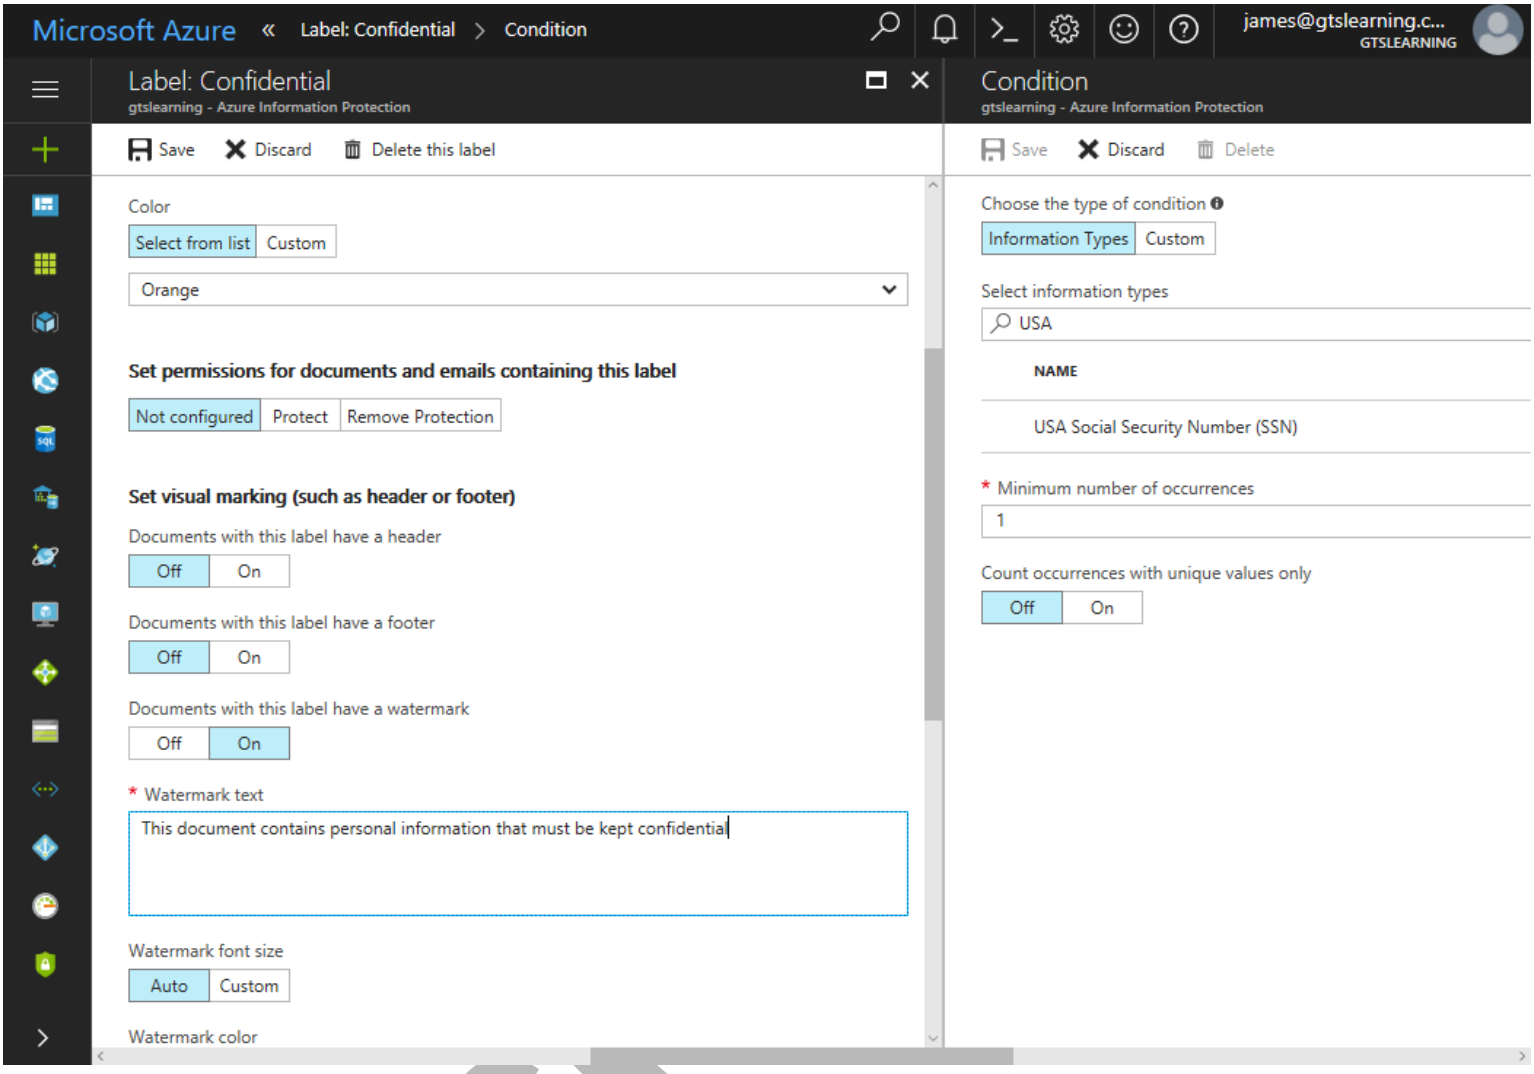
Data Classifications

Data classification and typing schemas tag data assets so that they can be managed through the information lifecycle. A data classification schema is a decision tree for applying one or more tags or labels to each data asset. Many data classification schemas are based on the degree of confidentiality required:

Public (unclassified) — there are no restrictions on viewing the data. Public information presents no risk to an organization if it is disclosed but does present a risk if it is modified or unavailable.

Confidential (secret) — the information is highly sensitive, for viewing only by approved persons within the owner organization and possibly by trusted third parties under NDA.

Critical (top secret) — the information is too valuable to allow any risk of its capture. Viewing is severely restricted.



Using Microsoft Azure Information Protection to define an automatic document labeling and watermarking policy. (Screenshot used with permission from Microsoft.)

Another type of classification schema identifies the kind of information asset:

Classification	Description
Proprietary	Proprietary information or intellectual property (IP) is information created and owned by the company, typically about the products or services they make or perform. IP is an obvious target for a company's competitors, and IP in some industries (such as defense or energy) is of interest to foreign governments. IP may also represent a counterfeiting opportunity (movies, music, and books, for instance).
Private/personal data	This information relates to an individual identity. Private data examples include personally identifiable information (PII) such as names, addresses, social security numbers, financial information, and sensitive data like health records, login credentials, biometric data, and confidential business information.

Classification	Description
Sensitive	This label is usually used in the context of personal data privacy-sensitive information about a subject that could harm them if made public and could prejudice decisions made about them if referred to by internal procedures. As defined by the EU's General Data Protection Regulation (GDPR), sensitive personal data includes religious beliefs, political opinions, trade union membership, gender, sexual orientation, racial or ethnic origin, genetic data, and health information (ec.europa.eu/info/law/law-topic/data-protection/reform/rules-business-and-organisations/legal-grounds-processing-data/sensitive-data/what-personal-data-considered-sensitive_en).
Restricted	This classification refers to sensitive information that requires stringent controls and limited access due to its highly confidential nature. Restricted data typically includes data that, if disclosed or accessed by unauthorized individuals, could cause significant harm to individuals, organizations, or national security.

Government and Military classifications can correspond to security-clearance levels used for military members, government officials, and civilian contractors. The structure will be similar to the following:

Government Classification	Explanation
Unclassified	Data that is available for public use. No clearance is needed.
Sensitive	Sensitive data is unclassified, but the government would prefer that the data not be public.
Confidential	Confidential data is information with limited distribution. No clearance is required.
Secret	The first data classification that requires a security clearance.
Top Secret	The highest level of data classification. Only those with Top Secret clearance can view the documents on a need-to-know basis.
Top Secret Compartmentalized	This data is not any more secret than Top Secret but has very specific and limited distribution.

13.1.5 Privacy and Responsibility of Data (Lesson Video)

Transcript:

We're going to spend a few minutes reviewing some of the laws that have been enacted to protect the privacy of electronic data.

The United States has passed a significant number of laws regarding information security, especially the privacy of electronic data. Prior to the year 2000, there weren't many laws that addressed this particular area of information security. However, due to a rash of break-ins, exploits, and another abuses, many states and the federal government enacted laws to protect the privacy of electronic data.
A key thing to remember is that you need to be very familiar with the requirements of the laws that apply to your organization. To protect your organization and to protect yourself, you need to be aware of how these laws apply to your organization.

This lesson addresses some of the higher profile data privacy laws, but it doesn't identify all the laws that apply to your organization, nor does it provide minute details of each law that it does cover. This lesson provides only a simple, high-level overview of these laws. You are responsible to research whether these laws apply to your organization, and if so, how. You are also responsible to be aware of other federal, state, and even local laws that effect your organization.

Let's begin with the Health Insurance Portability and Accountability Act of 1996 called HIPAA. HIPAA specifies that all organizations having anything to do with healthcare must protect the health information that they maintain.

These organizations must implement policies and procedures to protect this information, regardless of the storage medium, such as paper in a filing cabinet or electronic digital format. HIPAA also establishes national standards for transferring electronic healthcare information.

The next act you need to be familiar with is the Sarbanes-Oxley Act of 2002. The Sarbanes-Oxley Act of 2002, sometimes referred to as Sarbox, is the result of a flood of corporate fraud in the late 1990s and the early 2000s. Sarbox requires publically traded companies to adhere to very stringent reporting requirements and implement strong controls on electronic financial reporting systems.

A key point in Sarbox is that organizations have to keep information for a certain time. This especially relates to email. In fact, Sarbox created an entire industry of email archiving companies so that organizations can comply with its regulations.

Next, we need to look at the Gramm-Leach-Bliley Act, which we refer to as GLBA. GLBA is designed to protect private data much like HIPAA does; however, GLBA applies to private information held at financial institutions.

There are two main functions of GLBA. First, it requires all banks and any other financial institutions to alert their customers as to that organization's privacy policies. If you've received a little pamphlet from your financial institution that contained that institution's privacy statement, that pamphlet was in response to the Gramm-Leach-Bliley Act.

In addition, all personally identifiable financial information (PII) within a financial institutionâ€”either electronic or paper formatsâ€”has to be protected. Essentially this act specifies that a policy must be in place to protect private information from foreseeable threats and to maintain data integrity. In order to implement this, GLBA requires financial institutions to put in place three main components.

The first one is the Financial Privacy Rule. The second one is the Safeguards Rule. And the third one is called Pretexting Protection. Essentially, the Financial Privacy Rule requires all financial institutions to provide each customer with the privacy notice that we talked about earlier. It must be provided at the time the relationship is established. That is, when you go in to open a new banking account. It also has to be provided every year thereafter.

The Safeguards Rule requires financial institutions to develop a written information security plan, which describes in detail how the company plans to protect clients' personal information. Finally, Pretexting Protection encourages financial institutions to train their staff how to recognize social engineering exploits, which they call pretexting. The reason is that social engineering exploits use some type of pretext.

You should also be familiar with the Patriot Act of 2001. This act enables law enforcement agencies to detect and suppress terrorism by giving law enforcement the authority to request information from organizations. All organizations, public or private, must provide the requested information to the appropriate law enforcement agencies under the authority of a valid court order or a subpoena.

The next law you need to be familiar with is the California Database Security Breach Act of 2003. This law specifies that any agency, person, government entity, or company that does business in the state of California must inform California residents within 48 hours if a database breach or other security breach occurs in which personal information has been stolen or is believed to have been stolen.

Most other states have similar state laws modeled on the California Database Security Breach Act of 2003, making it a significant act. Therefore, use your favorite search engine to search for similar acts in the states in which you do business. If you do business in those states and your organization has a breach of personal information, then you are under a regulatory compliance requirement to inform anyone who may be affected.

Next, let's look at the Children's Online Privacy Protection Act of 1998, which is referred to as COPPA.

COPPA requires organizations that provide online services designed for kids below the age of 13â€”such as websites and gaming sitesâ€”to obtain parental consent prior to collecting a child's personal information and using it, such as displaying it on the website, selling it to a marketing company, and so on.

In addition, COPPA also specifies that such online services cannot require kids to provide more information than what they determine as reasonable in order to participate.

The General Data Protection Regulation, or GDPR, is a data compliance regulation that started in 2018. GDPR provides sweeping changes to the way customer data is treated in the European Union. The regulation not only applies to countries that are part of the EU, but it also applies to any company that has customers that reside in the EU itself. The regulation requires companies to be prepared to tell costumers what data they have, where they got it, who they've given it to, and how it's being used. It also gives customers the right to be forgotten in some cases. Failure to adhere to the regulations can be costly.

The last one we'll look at is the California Consumer Privacy Act, or CCPA, was passed in 2020 and was one of the first data privacy acts in the United States. The act applies to California state residents, but companies that do business in the state and

meet other benchmarks must also comply. The consumers' rights include the right to know what data is collected and whether their data was sold and to whom. The consumer is also allowed to access their own data and able to deny the sale of it. Under certain circumstances, they're allowed to have data deleted and cannot be discriminated against for doing so.
That's it for this video. This is not an all-inclusiveÂ list of laws and acts regarding electronic data privacy with which you need to be familiar. GDPR and CCPA are both relatively new, so make sure you research laws that apply to your organization beyond just these two. It's also probably a good idea to use the servicesÂ of a lawyer who's familiar with this field just toÂ make sure that your organization stays in compliance.Â Please note again that non-compliance to these laws and regulations can be very costly.

13.1.6 Privacy and Responsibility of Data

Privacy data refers to personally identifiable or sensitive information associated with an individual's personal, financial, or social identity, including data that, if exposed or mishandled, could infringe upon an individual's privacy rights.

This lesson covers the following topics:

- Privacy data
- Legal implications
- Roles and responsibilities
- Right to be forgotten
- Ownership of privacy data
- Data inventories and retention

Privacy Data

Examples of privacy data include names, addresses, contact information, social security numbers, medical records, financial transactions, and, generally, any other data that can be used to identify a specific person. Privacy data and confidential data have certain similarities. Both types of data require protection due to their sensitive nature. Unauthorized access, disclosure, or misuse of privacy or confidential data can negatively affect individuals or organizations.

Additionally, privacy and confidential data are subject to legal and ethical considerations. Organizations must comply with relevant laws and regulations, such as data protection and privacy laws, to safeguard both data types. However, there are also notable differences between privacy data and confidential data.

Confidential data encompasses any information that requires protection due to its confidential nature, regardless of whether it pertains to an individual. Examples include trade secrets, intellectual property, financial statements, proprietary algorithms, source code, and other nonpublic information. Privacy data, on the other hand, specifically refers to information that can identify or impact an individual's privacy. Confidential data is primarily concerned with safeguarding information from unauthorized access, use, or disclosure to maintain business competitiveness, protect intellectual property, or preserve the integrity of sensitive company data.

Privacy data focuses on protecting personal information to preserve an individual's privacy rights, prevent identity theft, and maintain the confidentiality of personal details. Privacy data is closely associated with the rights of individuals to control the use and disclosure of their personal information. Individuals have the right to access, correct, and request the deletion of their privacy data. In contrast, confidential data typically does not grant specific rights to the data subjects , as it relates more to organizations' proprietary information. The handling of privacy data often requires explicit consent from the data subject for its collection, use, and disclosure, particularly in compliance with privacy laws and regulations. On the other hand, confidential data, while protected, may not necessarily require individual consent for its handling, as it is associated with internal or business-related information.

Privacy and confidential data share similarities in sensitivity and legal considerations. However, scope, focus, data subject rights, and consent requirements differ. While both types of data require careful handling and protection, privacy data pertains explicitly to personal information and individual privacy rights.

Legal Implications

Protecting privacy data carries significant local, national, and global legal implications. Many countries have specific privacy laws and regulations that dictate how personal data should be handled within their jurisdiction. These laws define the rights of individuals, the responsibilities of organizations, and the procedures for data protection and privacy enforcement. At the national level, data protection authorities or supervisory bodies enforce privacy laws and oversee compliance. They have the authority to investigate data breaches, issue fines, and take legal action against organizations that fail to protect privacy data or violate individuals' privacy rights. The General Data Protection Regulation (GDPR) in the European Union has had a substantial impact globally by setting high privacy and data protection standards. GDPR applies to organizations that process the personal data of EU residents, regardless of their physical location. This extraterritorial effect ensures that organizations worldwide adhere to GDPR principles when handling EU citizens' personal data. Cross-border data transfers are also subject to specific requirements and restrictions. For example, the GDPR restricts transferring personal data outside the European Economic Area unless adequate safeguards exist to protect privacy data. Understanding and adhering to these legal requirements are essential to avoid legal consequences, maintain trust with individuals, and foster a global culture of privacy and data protection.

Roles and Responsibilities

Data controller and data processor are two distinct roles defined under data protection regulations, such as the General Data Protection Regulation (GDPR). Although they deal with personal data, these roles have important similarities and differences. The data controller and data processor are involved in handling personal data. Both roles are responsible for ensuring personal data protection in compliance with data protection laws and regulations. The data controller and data processor must also adhere to data protection laws. They are required to process personal data lawfully, securely, and transparently.

The primary distinction lies in their roles and responsibilities. The **data controller** is the entity or organization that determines the purposes and means of processing personal data. They have overall control and responsibility for the processing of personal data. The data controller decides why and how personal data is processed. They exercise decision-making authority, define the purposes of data processing, and determine the categories of data to be processed. Data controllers have direct legal obligations and responsibilities under data protection laws. They are accountable for handling compliance, obtaining appropriate consent from data subjects, providing privacy notices, implementing data protection policies and procedures, and handling data subject requests. The **data processor** processes personal data on behalf of the data controller. They act under the authority and instructions of the data controller. Data processors do not have independent decision-making power over personal data. They process data solely as instructed by the data controller. Data processors have legal obligations to process personal data only for the purposes defined by the data controller. They must implement appropriate security measures, maintain the confidentiality and integrity of the data, and cooperate with the data controller to meet their legal obligations. Data processors are also required to keep records of their processing activities. Data processors include cloud service providers or payroll processing companies, for example.

A data subject refers to an individual whose personal data is processed by an organization or other entity. They are the individuals to whom the personal data refers. Data subjects hold certain rights and protections under data protection laws, such as the General Data Protection Regulation (GDPR) and the California Consumer Privacy Act (CCPA). One of the rights afforded to data subjects is the right of access, meaning that data subjects have the right to request access to their personal data and obtain information about how it is being processed. Subjects can inquire about the purposes of processing, the categories of data being processed, recipients of the data, and the duration of data retention. Data subjects have the right to rectification, which means that if data subjects discover that the personal data held by an organization is inaccurate or incomplete, they have the right to request its correction to ensure that their personal data is up to date and accurate. Data subjects also have the right to request the erasure or removal of their personal data under certain circumstances.

For example, if the data is no longer necessary for the purposes it was collected, or if the data subject withdraws their consent for its processing, they can request its deletion. Data subjects can request the restriction of processing their personal data. The implications are that while privacy data can still be stored, it cannot be processed further except under specific conditions. This

right gives data subjects control over their personal data's ongoing use. Data portability is another right granted to data subjects. Subjects have the right to receive their personal data in a commonly used and machine-readable format, ensuring their ability to move and transfer their personal information as desired. Data subjects have the right to object to processing their personal data based on specific grounds. Examples include if a subject believes their data is being processed for purposes that are not legitimate or if they wish to object to direct marketing activities. Lastly, data subjects have the right to withdraw their consent for the processing of their personal data. If the processing is based on their consent, they can revoke it at any time, and the organization must cease processing the data accordingly.

Data subjects exercise these rights by contacting the data controller, who ensures that data subject rights are respected, facilitating the exercise of these rights, and addressing any concerns or requests from data subjects.

Right to Be Forgotten

The "right to be forgotten" is a fundamental principle outlined in the General Data Protection Regulation (GDPR) that grants data subjects the right to request the erasure or deletion of their personal data under certain circumstances. It empowers individuals to have their personal information removed from online platforms, databases, or any other sources where their data is being processed and made publicly available.

The right to be forgotten recognizes the importance of individual privacy and control over personal data. Upon receiving a valid erasure request, the data controller must erase the personal data promptly unless there are legitimate grounds for refusing the request. This right extends to the removal of data from the organization's systems and to any third parties with whom the data has been shared or made publicly available. This right may be limited if the processing of personal data is necessary for exercising the right of freedom of expression and information, compliance with a legal obligation, or the establishment, exercise, or defense of legal claims. The right to be forgotten serves as a mechanism for individuals to regain control over their personal information. It promotes privacy and data protection by enabling subjects to remove personal data when it is no longer necessary or lawful to retain it.

Ownership of Privacy Data

The question of ownership regarding privacy data is a complex topic. In general, it is not easy to attribute traditional notions of ownership to privacy data. The ownership of privacy data is often not considered in terms of traditional property rights. Under many data protection laws, such as the GDPR, the emphasis is placed on the rights and protections of the data subject rather than determining ownership. The data subject has control over their personal data and can exercise certain rights, such as the right to access, rectify, and delete their data.

However, organizations that collect and process personal data are considered custodians or stewards of the data rather than owners. They have legal and ethical responsibilities to handle personal data securely and lawfully and to respect the rights of the data subjects. It is important to note that privacy data often consists of information about individuals, and those individuals have a strong interest in protecting their personal information. Data protection laws aim to provide individuals with control and protection over their personal data, ensuring transparency, consent, and fair processing practices. While the concept of ownership might not directly apply to privacy data, individuals have rights and control over their personal information, and organizations are legally accountable for handling the data responsibly. The focus is on safeguarding privacy rights and ensuring data protection rather than assigning ownership in the traditional sense.

Data Inventories and Retention

Privacy laws profoundly impact data inventories and data retention practices within organizations. These laws, such as the GDPR and CCPA, require organizations to maintain a detailed record of the personal data they collect, process, and store. Data inventories provide a comprehensive overview of the types of data being handled, the purposes for processing, the legal basis, and recipients of the data to ensure transparency and accountability, as organizations can clearly understand and document their data processing activities in compliance with privacy laws. Privacy laws stipulate that organizations must have a lawful basis for processing personal data. Data inventories are crucial in identifying the legal grounds for data processing. By documenting the legal basis for each category of personal data, organizations can ensure that their processing activities align with the specified lawful purposes outlined in privacy laws. Organizations must collect and process only the necessary elements of personal data for

specific and legitimate purposes. Data inventories assist organizations in evaluating the personal data they collect, ensuring they only gather necessary information. By keeping the inventory up to date, organizations can align their practices with the principles of data minimization and purpose limitation.

Data retention is another area impacted by privacy laws. Organizations must retain personal data only for as long as necessary to fulfill the intended purpose or as required by law. Data inventories help organizations determine appropriate retention periods for different categories of personal data, ensuring compliance with data storage limitation requirements. Keeping accurate records in the data inventory enables organizations to securely delete or anonymize data when it is no longer needed. Privacy laws grant individuals various rights, such as the right to access their personal data. Data inventories are instrumental in facilitating the exercise of these rights. By maintaining comprehensive inventories, organizations can promptly respond to data subject requests, provide individuals with access to their data, rectify inaccuracies, and fulfill requests for erasure in accordance with privacy laws.

Furthermore, privacy laws mandate implementing robust security measures to protect personal data. Data inventories help organizations identify their personal data types and all associated security requirements. By clearly understanding the data they process, organizations can implement appropriate technical and organizational safeguards to shield personal data from unauthorized access, loss, or alteration, thus ensuring compliance with security obligations under privacy laws.

13.1.7 Data Destruction (Lesson Video)

Transcript:

When you dispose of a computer, selling used hardware, or erasing important information, it's crucial to destroy all of the data on a device. It's not enough to delete the data. Reformatting the hard drive is not even sufficient. If other people can access your computer, they can use data remanence, the residual representation of erased data, to recover information. You must damage the hardware so badly that the remanence is gone.

And don't paper documents. Even in our digital world, a lot of sensitive information is available in print, and you must destroy that information, too. If someone obtains your data, it might be used to crack passwords, sell identification information, or steal trade secrets. That's why it's essential to be familiar with the tools, techniques, and government laws that apply to data destruction.
There are wrong ways to destroy data and then there is the right way. You must use specialized tools to destroy data remanence, so information is impossible to retrieve. Data destruction tools use one of three techniques.
Software programs write random code over and over on top of the original data so that anything that can be recovered from the hardware is just gibberish.
Hardware tools damage hard disk drives so severely that it is impossible to retrieve even pieces of data from the drive.
There are also techniques that destroy the ink on paper so that it's impossible to read.
Let's look at sanitization programs first. Sanitization programs wipe data off your computer without damaging hardware. This is commonly called purging, wiping, or clearing. These techniques remove data from the hard disk and then write over it so many times that the data remanence is destroyed.
Media sanitization options do not destroy the hard disk for future use. There are many data sanitization software programs you can use to purge information, and some of them are even free. Each has pros and cons; carefully consider the media type you are purging, the level of data sensitivity, your budget, and other factors when you select a sanitization software.
The following options severely damage hardware storage so that the device can never be used again.
One technique is running a hard disk through a disk shredder, physically destroying the drive. Disk shredders are effective, but also relatively expensive.
Some organizations without a disk shredder will destroy a disk by hammering or drilling holes into the disk platters. Drilling and hammering are relatively inexpensive and fairly efficient. However, they are not as effective as a shredder.
Another option is hiring a company to destroy disks. Many companies that provide this service will also provide a certificate of destruction.
Pulverizing is like shredding, except that it uses a punch press or hammer system to crush a hard disk into a pile of metal confetti. Many companies that provide disk shredding also provide pulverizing.
One really effective technique is degaussing. Degaussing purges the hard disk by exposing it to an incredibly high magnetic pulse that destroys all the data on the disk. It also ruins the motors inside the drive.
Remember how we mentioned that you also need to destroy paper documents that contain sensitive information? Most offices contain paper shredders, which shred documents into very small pieces, as small as one-seventeenth of an inch which are then

mixed with other trash. But these paper pieces still contain ink. There are two methods that destroy the ink on the paper: burning and pulping.
Burning documents is a pretty simple process. Build a small fire somewhere legal and safe, then use metal tongs to burn your documents one by one or a few at a time. It's important to ensure that each document is turned into ash, if sensitive information escapes the flames and flies away, it might fall into the wrong hands.
Burning blank papers with your critical documents makes things more confusing if someone tries to piece them back together. Be sure to sift through all the remains and make sure every bit of paper has turned to ash before you dispose of the burnt remnants.
Pulping is a way of removing all traces of ink from paper by using chemicals and then mashing the paper into pulp. Since these chemicals can ruin carpet and clothing, you should perform this process outside and use protective gloves.
First, you need to remove the documents from envelopes, unfold them, and place them in a large trash can filled with nine parts water and one part liquid bleach. Second, completely submerge and soak the documents in the solution for 24 hours. Next, use a broomstick or a heavy-duty mixer, such as a paint turbine mixer, to mash the paper into a pliable liquid pulp.
After that, spread the pulp out to dry in the sun. Lastly, place the dried pulp into garbage bags and throw it in the trash.
Now that we have discussed ways to permanently dispose of information, let's switching gears to talk about the legal requirements of data destruction, starting with data sovereignty. Data sovereignty is the concept that information stored in binary digital form is subject to government laws and regulations. Data sovereignty laws are created to maintain privacy and prevent foreign countries from subpoenaing, or searching, another's data. Data sovereignty laws evolve rapidly as cloud services and other new storage options emerge.
It's imperative that you stay current with data sovereignty laws because every business must comply with state and federal data destruction regulations. Data sovereignty laws protect citizens from identity theft, companies from security breaches, and clients from privacy issues. They specify when, how, and what data you are allowed to destroy. Requirements vary depending on location, so make sure you comply with the most up-to-date version of both state and federal regulations, and remember, they frequently change to keep up with the pace of technology. No matter where you live in the US, you will have to follow laws dictated by three government acts: HIPAA, FACTA, and FISMA.
HIPAA stands for Health Insurance Portability and Accountability Act. HIPAA protects medical records and personal health information. Companies that provide healthcare insurance handle HIPAA-protected information. And, of course, companies that provide health-related services also handle HIPAA-protected information.
FACTA, the Fair and Accurate Credit Transactions Act, was created to protect against identity theft. It applies to the disposal of consumer reports and related information. FACTA includes credit reports, credit scores, employment history information, check writing history, insurance claims, residential or tenant history, and medical history. Every business handles FACTA-protected information, and every business must comply with FACTA laws.
FISMA, the Federal Information Security Management Act, protects government information. It is primarily concerned with proper data destruction and has detailed disposal requirements.
Regardless of which destruction method you use and what type of information you destroy, you need to carefully document each disposal process with a certificate of destruction, or COD. A COD is usually necessary to satisfy internal security reporting requirements as well as legal reporting requirements.
A COD should specify the device and the method and date of destruction. This document should also provide a chain of custody (each person who had possession of the data and the length of time they possessed the data).
If you destroy a storage device yourself, you should create your own COD. You can find COD templates on the internet. If you contact a service provider to destroy your devices, request that they provide a COD for each device they process. Most organizations, especially military and government agencies, retain CODs as a permanent record of each device's destruction.
Companies should have data retention policies and procedures for storing and destroying information. By law, organizations must retain certain information for specified time periods, and your business probably has additional records to keep and maintain. Always make absolutely certain that it is okay to destroy papers, data, and drives.
Remember, proper data destruction is essential to securing information. Not only must you use specialized tools and techniques to damage the data beyond recovery, you must also comply with all necessary laws and company policies, including creating and maintaining a certificate of destruction. Following these guidelines will protect your organization from many security and legal problems.

13.1.8 Data Destruction Facts

When a device is no longer needed, it often contains residual data, potentially sensitive information, and system configurations that could be exploited. A thorough and systematic decommissioning process ensures that all data is securely erased or overwritten to reduce the risk of exposure.

This lesson covers the following topics:

Decommissioning

Secure data destruction

Asset disposal

Decommissioning

Decommissioning processes play a vital role in supporting security within an organization. Decommissioning also involves resetting devices to their factory settings and eliminating any residual settings. Updating inventory records during decommissioning is also important to maintain an accurate account of active assets and support compliance requirements that mandate accurate asset tracking and secure disposal.

Decommissioning hardware securely is essential as hardware often stores sensitive data on internal drives and retains potentially exploitable configuration and user data. Data sanitization is a critically important step in the decommissioning process. It describes how all data on the device or removable media is securely erased to ensure no recoverable data remains.

Additionally, the device should be reset to its factory settings via a management console or other utility, eliminating any residual system configurations or settings that could pose a security risk. Disposing of physical equipment often warrants the physical destruction of some internal components like memory modules, hard disk drives (HDD), solid-state disks (SSD), M.2, or other storage modules, especially if they have stored sensitive data. In some scenarios, a professional disposal service specializing in certified secure disposal of electronic components may be the most appropriate choice.

The final step in the decommissioning process involves documentation and updating inventory records to reflect that the device has been decommissioned. This step ensures an accurate asset record and compliance with security standards and regulations.

For example, a multifunction network printer's decommissioning steps include sanitization of stored print jobs, scanned documents, and (potentially) fax transmissions; wiping stored network credentials and configuration data; performing a full factory reset; secure disposal or destruction of physical components; and asset inventory updates to reflect the device's status.

Secure Data Destruction

Several common circumstances may necessitate data destruction within an organization to ensure security, compliance, and proper management of resources. At the end of a data retention period, organizations must destroy data in accordance with internal policies and external regulations while optimizing storage resources. Legal and regulatory compliance, such as adhering to the General Data Protection Regulation (GDPR) or the Health Insurance Portability and Accountability Act (HIPAA), also requires the deletion or destruction of specific data when it is no longer needed or if requested by the data subject. Periodically destroying obsolete or outdated data can help maintain efficient storage utilization and reduce the risk of data breaches.

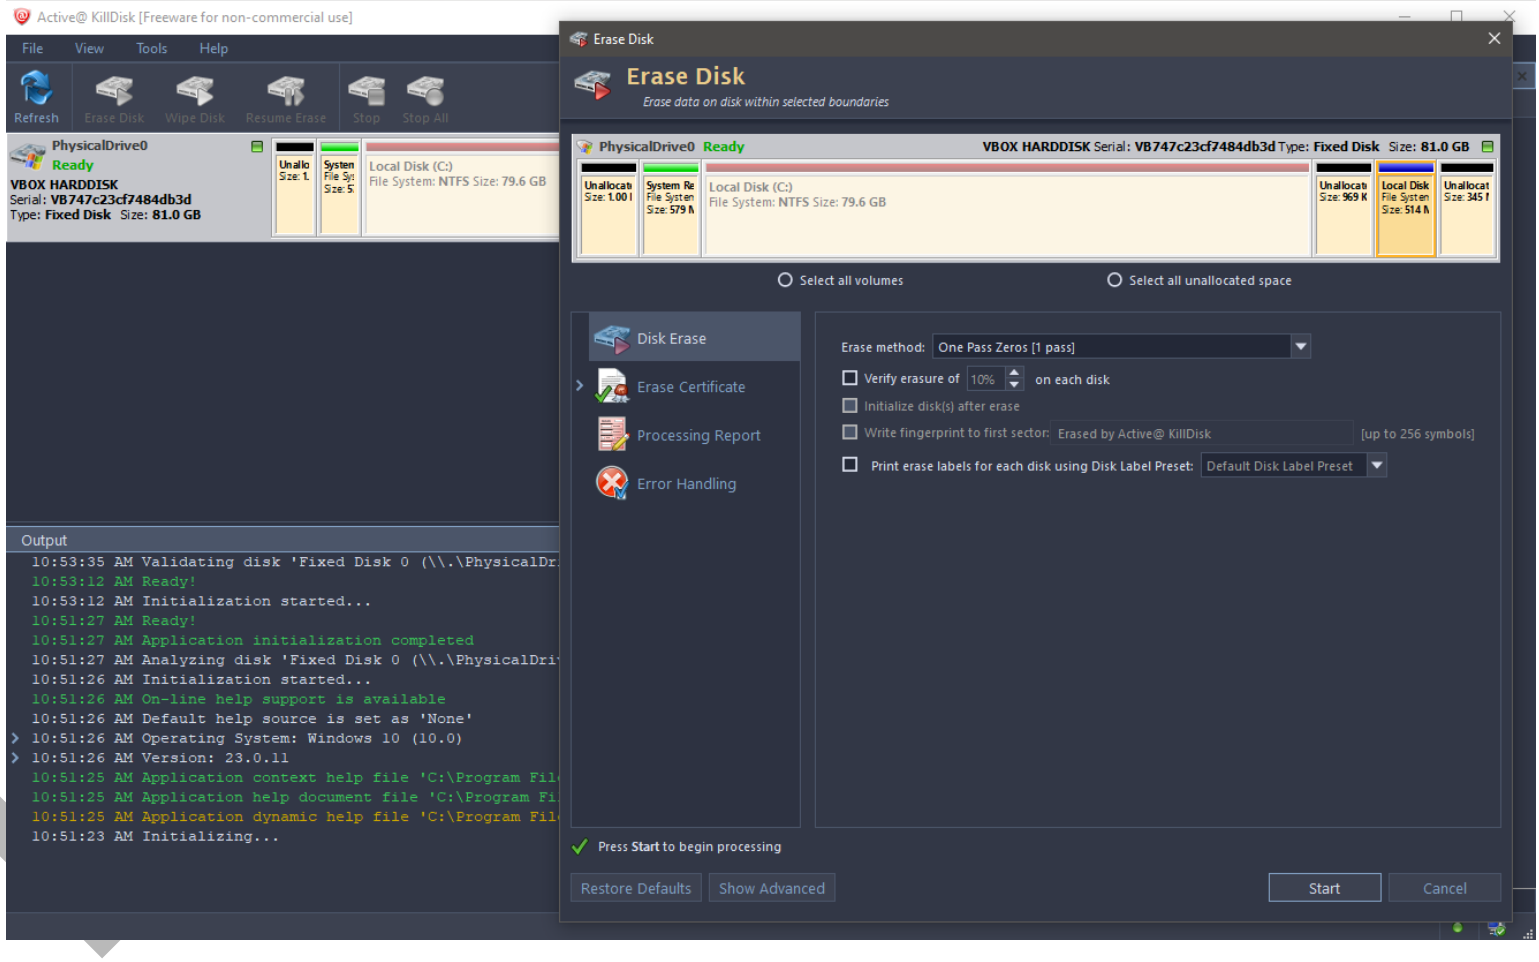
Additionally, when decommissioning storage devices or systems, destroy any stored data before disposal or repurposing to prevent unauthorized access to sensitive information.

Asset Disposal

Asset disposal/decommissioning concepts focus on the secure and compliant handling of data and storage devices at the end of their lifecycle or when they are no longer needed. Some important concepts include the following:

Concept	Description
Sanitization	Refers to the process of removing sensitive information from storage media to prevent unauthorized access or data breaches. This process uses specialized techniques, such as data wiping, degaussing,

Concept	Description
	or encryption, to ensure the data becomes irretrievable. Sanitization is particularly important when repurposing or donating storage devices, as it helps protect the organization's sensitive information and maintains compliance with data protection regulations.
Destruction	Involves the physical or electronic elimination of information stored on media, rendering it inaccessible and irrecoverable. Physical destruction methods include shredding, crushing, or incinerating storage devices, while electronic destruction involves overwriting data multiple times or using degaussing techniques to eliminate magnetic fields on storage media. Destruction is a crucial step in the decommissioning process and ensures that sensitive data cannot be retrieved or misused after the disposal of storage devices.
Certification	Refers to the documentation and verification of the data sanitization or destruction process. This often involves obtaining a certificate of destruction or sanitization from a reputable third-party provider, attesting that the data has been securely removed or destroyed in accordance with industry standards and regulations. Certification helps organizations maintain compliance with data protection requirements, provides evidence of due diligence, and reduces the risk of legal liabilities. Certifying data destruction without third-party involvement can be challenging, as the latter provides an impartial evaluation.



Active KillDisk data wiping software. (Screenshot used with permission from LSoft Technologies, Inc.)

Files deleted from a magnetic-type hard disk are not fully erased. Instead, the sectors containing the data are marked as available for writing, and the data they contain are only removed as new files are added. Similarly, the standard Windows format tool will only remove references to files and mark all sectors as usable. For this reason, the standard method of sanitizing an HDD is called **overwriting** . This can be performed using the drive's firmware tools or a utility program. The most basic type of overwriting is called zero filling, which sets each bit to zero. Single pass zero filling can leave patterns that can be read with specialist tools. A more secure method is to overwrite the content with one pass of all zeros, then a pass of all ones, and then a third pass in a pseudorandom pattern. Some federal agencies require more than three passes. Overwriting can take considerable time, depending on the number of passes required.

13.1.9 Privacy and Data Sensitivity Concepts

13.1.10 Practice Questions (Section Quiz)

q_breaches_data_breach_secp8

Which of the following can be consequences of a data breach? (Select three.)

Answers:

***Reputation damage**

***Fines**

***Identity theft**

Escalation

Financial penalties

Legal liabilities

Reputational damange

Explanation:

Data breaches can reflect negatively on a business and its ability to protect sensitive consumer information. Breaches can make consumers less likely to use the business again, damaging the company's reputation.

Fines are money that a court of law or another authority has levied on a company or a person as a penalty for wrongdoing. Fines are a consequence of data breaches.

Identity theft is intentionally using someone else's identity to gain a financial advantage or benefit without the other person's knowledge. Identity theft can be a consequence caused by breaches of usernames, passwords, or personally identifiable information (PII).

The following are not normally consequences of a data breach:

Escalation is the process of moving a problem or concern to a higher level of authority or deeper expertise.

Noncompliance can result in legal sanctions such as financial penalties, legal liabilities, reputational damage, and loss of customer trust.

q_breaches_escalation_secp8

As the chief information security officer (CISO) of a multinational corporation, you discover a significant data breach that has potentially exposed sensitive proprietary information.

What is the MOST crucial action you should take to mitigate the consequences of this breach?

Answers:

Notify the customers about the breach.

Pay the fines associated with the breach.

***Escalate the issue internally and externally to bring in experts for investigation.**

Work on repairing the company's reputation damage.

Explanation:

Escalating the issue internally and externally is the correct answer. In the case of a breach involving sensitive proprietary information, it is crucial to bring in experts for investigation as quickly as possible. This can help determine the extent of the breach, identify the perpetrators, and take necessary steps to prevent further damage.

Notifying customers about the breach is an important step when customer data is compromised. However, in this scenario, the breach involves proprietary information, not customer data. Therefore, the immediate action should be to escalate the issue to bring in experts for investigation.

Paying the fines associated with the breach is a consequence of a data breach, not an immediate action to mitigate its effects. Fines are typically levied after an investigation and determination of the company's compliance with data protection laws.

Repairing the company's reputation damage is a long-term process that comes after addressing the immediate needs of the breach, such as escalating the issue and investigating the breach. While it's an important aspect of recovery, it's not the most immediate action to take following a breach.

q_breaches_fines_01_secp8

A tech startup has just suffered a data breach where sensitive customer financial data leaked.

The chief executive officer (CEO) has an immediate concern about the tangible penalty the company will face due to violating data protection regulations.

What is the CEO primarily concerned with in this situation?

Answers:

Privacy policy updates

Reputational damage

***Fines**

Security infrastructure overhaul

Explanation:

Regulatory authorities impose fines as immediate, tangible penalties on companies violating specific regulations.

Privacy policy updates encompass changes in the company's stated data handling practices. Despite their importance, they do not serve as an immediate penalty for violating data protection regulations.

Non-compliance results in significant but intangible reputational damage, causing harm to the company's image among customers and stakeholders. However, this concern is not the CEO's immediate focus.

To address a data breach, a security infrastructure overhaul involves completely revamping the company's security systems. However, this is not an immediate, tangible penalty.

q_breaches_fines_02_secp8

A board of directors receives a memorandum that two departments in the organization violate federal regulations.

What could the organization receive that would monetarily impact them if sanctioned?

Answers:

***Fines**

Reputational damage

Loss of license

Indemnification

Explanation:

Sanctions refer to penalties, disciplinary actions, or measures imposed due to noncompliance with laws, regulations, or rules. Regulators may impose substantial fines, which can amount to millions or even billions of dollars, depending on the severity of the violation.

Not directly impacted by sanctions, noncompliance can harm an organization's reputation, eroding customer trust, decreasing business opportunities, and potentially losing contracts or partnerships.

Not impacted by sanctions, noncompliance with software usage can result in contractual noncompliance, leaving work products vulnerable.

Indemnification is not directly associated with the impacts of a sanction but may result in the noncompliant part assuming liability for damages caused by a security breach or data loss.

q_breaches_indemnification_secp8

A cyber team evaluates areas that pose more risk of becoming noncompliant.

What is the ramification of indemnification?

Answers:

***Liability for damages caused by data loss**

Modifying code or distributing software

Exceeding permitted installations

Unauthorized sharing or usage

Explanation:

Not associated with software licensing but applicable to this scenario, indemnification occurs as the result of damages caused by a security breach or data loss.

Noncompliance with software licensing requirements can result in the revocation of usage rights and other consequences, such as fines. Violations of license agreements, such as modifying code or distributing software without authorization, constitute noncompliance with the owner of the software.

Other forms of noncompliance for software licensing include the organization exceeding the permitted number of installations.

The unauthorized sharing or other unauthorized usage can also jeopardize a loss of software licensing due to noncompliance.

q_breaches_iptheft_secp8

Your organization has discovered that an overseas company has reverse-engineered and copied your main product and is now selling a counterfeit version.

Which of the following BEST describes the type of consequence your organization has suffered?

Answers:

Fines

Escalation

Reputation damage

***IP theft**

Explanation:

Intellectual property (IP) is the lifeblood of companies. When their IP is stolen, they lose competitive advantage. The internet has made the world smaller, and companies are now competing with others from around the globe. When IP is stolen through a data breach, it is often sold to competing companies. Many of the companies are overseas and not subject to laws in the United States, making them difficult to prosecute. This allows reverse-engineering or direct copying of IP and gives thieves an undeserved revenue source. This also floods the market with counterfeit goods.

A company's reputation determines if people invest, if consumers buy a product or service, or if foreign governments even allow a certain company to do business in their jurisdiction. This scenario does not describe this.

Fines can be levied against an organization as a result of a data breach. This scenario does not describe this.

Escalation can be separated into two categories, which are internal escalation and external escalation. Internal escalation is part of a company's incident-response plan. External escalation is when experts need to be brought in from the outside to investigate, provide legal counsel, or even enforce laws.

q_breaches_noncompliance_secp8

What describes the impacts associated with contractual noncompliance?

Answers:

***It can result in a breach or termination of an agreement or indemnification.**

It can grant certain individuals to challenge credit data on their personal reports.

It can include financial penalties, legal liabilities, and loss of customer trust.

Numerous governing bodies, such as regulatory authorities, can oversee the organization.

Explanation:

Contractual noncompliance occurs when organizations fail to meet agreed requirements, possibly resulting in a breach of contract, termination of the contract, or indemnification.

The "right to be forgotten" is a fundamental principle outlined in the General Data Protection Regulation (GDPR) that grants individuals the right to request the erasure or deletion of their personal data under certain circumstances.

Common ramifications for noncompliance include legal sanctions such as financial penalties, legal liabilities, and loss of customer trust. Sanctions refer to penalties, disciplinary actions, or measures imposed due to noncompliance with laws, regulations, or rules.

Sanctions enforcement is the responsibility of governing bodies, regulatory authorities, or organizations overseeing the specific domain in which the noncompliance occurred.

q_breaches_notification_secp8

As the chief information security officer (CISO) of a large corporation, you discover a significant data breach that has potentially exposed sensitive customer data.

What is the most immediate action you should take to mitigate the consequences of this breach?

Answers:

Escalate the issue internally and externally to bring in experts for investigation.

***Notify the customers about the breach.**

Pay the fines associated with the breach.

Work on repairing the company's reputation damage.

Explanation:

Notifying the customers about the breach is the correct answer. Each of the 50 states now have laws on breach notifications. Most of the laws have common elements. For example, a company must immediately disclose a breach to its customers in writing. This allows customers to take immediate action to protect themselves, which can help mitigate the overall impact of the breach.

Escalating the issue internally and externally is an important step in managing a data breach. However, it is not the most immediate action. The first step should be to notify the affected parties so they can take protective measures.

Paying the fines associated with the breach is a consequence of a data breach, not an immediate action to mitigate its effects. Fines are typically levied after an investigation and determination of the company's compliance with data protection laws.

Repairing the company's reputation damage is a long-term process that comes after addressing the immediate needs of the breach, such as notifying customers and investigating the breach. While it's an important aspect of recovery, it's not the most immediate action to take following a breach.

q_breaches_reputation_secp8

Your organization has suffered a data breach, and it was made public. As a result, stock prices have fallen, as consumers no longer trust the organization.

Which of the following BEST describes the type of consequence your organization has suffered due to the breach?

Answers:

Identity theft

Notifications

***Reputation damage**

IP theft

Explanation:

This scenario best describes an organization's reputation damage from a data breach. A company's reputation determines if people invest, if consumers buy a product or service, or if foreign governments even allow a certain company to do business in their jurisdiction. A company lives or dies by its revenues and investments, so a breach that exposes client data directly affects the way consumers and investors spend their money. A data breach can cause stock prices to fall, and falling stock prices lead to selloffs and permanent damage.

Notifications are usually sent out following a data breach. This scenario does not describe this.

Intellectual property (IP) is the lifeblood of companies. When their IP is stolen, they lose competitive advantage. This scenario does not describe this.

Identity theft is when a breach occurs and personal information is stolen. The affected individual or entity is forced to do hours of work to correct someone else's mistake.

q_breaches_sanctions_secp8

A board of directors convenes to discuss reports that the tech department was not meeting legal regulations.

What are the impacts associated with sanctions? (Select two.)

Answers:

***It can include financial penalties, legal liabilities, and loss of customer trust.**

***It can be overseen by numerous governing bodies, such as regulatory authorities.**

It can result in a breach or termination of an agreement, or indemnification.

It can grant certain individuals with the ability to challenge credit data on their personal reports.

It can result in information being read, modified, or deleted without authorization.

Explanation:

Typical ramifications for noncompliance include legal sanctions such as financial penalties, legal liabilities, and loss of customer trust. Sanctions refer to penalties, disciplinary actions, or measures imposed due to noncompliance with laws, regulations, or rules.

Sanctions enforcement is the responsibility of governing bodies, regulatory authorities, or organizations overseeing the specific domain in which the noncompliance occurred.

Contractual noncompliance occurs when organizations fail to meet agreed requirements, possibly resulting in a breach of contract, termination of the contract, or indemnification.

The "right to be forgotten" is a fundamental principle outlined in the General Data Protection Regulation (GDPR) that grants individuals the right to request the erasure or deletion of their personal data under certain circumstances.

A data breach occurs when information is read, modified, or deleted without authorization. It is not an impact of sanctions.

q_breaches_software_secp8

A cyber technician purchases new software to monitor employee computer usage after the company announces a new work-from-home program.

Which risks could lead to noncompliance with software agreements? (Select three.)

Answers:

***Modifying code or distributing software**

***Exceeding permitted installations**

***Unauthorized sharing or usage**

Liability for damages caused by data loss

Liability caused by a security breach

Data transferred to a network or storage media

Loss or disclosure of personal and sensitive data

Explanation:

Noncompliance with software licensing requirements can result in the revocation of usage rights and other consequences, such as fines. Violations of license agreements, such as modifying code or distributing software without authorization, constitute noncompliance with the owner of the software.

Other forms of noncompliance for software licensing include the organization exceeding the permitted number of installations.

The unauthorized sharing or other unauthorized usage can also jeopardize a loss of software licensing due to noncompliance.

Not associated with software licensing includes:

Indemnification occurs as the result of damages caused by a security breach or data loss.

Data transferred to a network or storage media

Loss or disclosure of personal and sensitive data

q_info_class_compliance_secp8

A multinational corporation handles regulated data. What are the key considerations for handling and protecting the data to ensure compliance?

Answers:

***Data subject to legal and regulatory requirements: privacy, security, compliance**

Data requiring encryption: secure storage, transmission, adherence to standards

Financial and trade secret data: reporting, risk management, non-disclosure agreements

Data requiring user awareness training: content filtering, web security, authentication

Explanation:

Regulated data refers to information governed by laws and regulations. Key considerations include privacy, security, and compliance with relevant requirements.

While encryption may be a consideration, it does not fully define regulated data, and the key considerations extend beyond encryption.

Regulated data encompasses more than financial and trade secret data; the key considerations mentioned are not comprehensive. Financial and trade secret data would not be key considerations for the organization to ensure compliance.

While user awareness training may be relevant, it does not fully capture the concept of regulated data and the broader key considerations for compliance.

q_info_class_confidential_secp8

A financial organization is currently handling a document that contains sensitive customer information, including financial details and social security numbers.

According to data classifications, how should the financial organization categorize this data?

Answers:

***Confidential data**

Trade secret data

Proprietary data

Restricted data

Explanation:

The information is highly sensitive, and only approved persons within the organization and possibly trusted third parties under the non-disclosure agreement (NDA) should view it. Since this data includes sensitive customer information, including financial details and social security numbers, the organization should classify it as confidential.

Trade secret data is a type of information that holds significant commercial value and is kept secret for competitive advantage.

Proprietary information or intellectual property is information the company creates and owns, typically about the products or services they make or perform.

While this data is sensitive, the term "restricted" usually applies to information that could cause significant harm to individuals, organizations, or national security if disclosed or accessed by unauthorized individuals.

q_info_class_financial_secp8

A multinational company is preparing to submit its annual statements and needs to share confidential reports with its global offices. The data includes the company's revenues, profits, and other sensitive information.

What data category do these annual statements fall under?

Answers:

***Financial data**

Trade secret data

Human-readable data

Regulated data

Explanation:

The annual financial statement, including all related financial information, falls into this category. Legal and financial data is sensitive and confidential and can significantly impact an organization's reputation, legal standing, and financial stability.

While the annual financial statement might contain sensitive and valuable information, it does not contain trade secrets such as proprietary formulas, processes, or methods that would give the company a competitive advantage.

Although the annual financial statement could classify as human-readable, as it can be easily understood and interpreted by humans, this category does not reflect the financial and legal significance of the data.

Regulated data typically includes personally identifiable information (PII), credit card details, and health records directly regulated by laws and regulations.

q_info_class_human_readable_01_secp8

A company's marketing team creates an infographic for an upcoming campaign, presenting detailed statistics and forecasts to better inform their audience about the product's performance.

In terms of data types, how would the marketing team classify this infographic?

Answers:

***Human-readable data**

Trade secret data

Legal and financial data

Regulated data

Explanation:

The infographic's design is to be easily understood and interpreted by humans without the need for additional processing or translation, making it human-readable data.

While the data contained in the infographic could be proprietary or confidential, it is for public marketing purposes, so it does not qualify as trade secret data.

Although the infographic might contain some performance statistics, the primary purpose of the infographic is not for legal compliance or financial reporting. Therefore, it does not fall under the legal and financial data type.

Regulated data typically includes personally identifiable information (PII) or other data types directly regulated by specific laws and regulations. Since the infographic does not contain such information, it is not regulated data.

q_info_class_human_readable_02_secp8

What type of data is information that can easily be understood and interpreted without additional processing or translation?

Answers:

Regulated data

Trade secrets

***Human-readable data**

Non-human-readable data

Explanation:

Human-readable data is information in a format directly comprehensible to humans without additional processing or translation.

Regulated data refers to categories of information subject to legal or regulatory requirements for their handling, storage, and protection. It does not necessarily mean humans can easily understand or interpret it without additional processing or translation.

Trade secrets refer to confidential business information that provides a competitive edge. Like regulated data, the trade secret category does not indicate the data is easily understandable or interpretable by humans.

Humans cannot easily understand or interpret non-human-readable data in its raw form, and it often requires additional processing or translation.

q_info_class_legal_secp8

An organization is preparing to file for a patent for its innovative product design. They have gathered all necessary information, including detailed descriptions of the design, how it differs from existing designs, and why it is eligible for patent protection.

Under which data type would this information fall?

Answers:

***Legal and financial data**

Human-readable data

Trade secret data

Regulated data

Explanation:

The patent application, including all related designs and justifications, falls into this category. Legal data include legal agreements, court records, intellectual property filings, and other legal documents that are of significant importance to an organization's legal standing.

While the patent information may be human-readable, this classification does not fully encapsulate the specific legal nature of the information.

Although the information about the design could be a trade secret until the organization files the patent, during the patent process, the information will be publicly accessible and not trade secret data.

This category typically includes personally identifiable information (PII) and other data types directly regulated by specific laws and regulations, and a patent does not fall into this category.

q_info_class_nist_secp8

Companies can categorize information security and cybersecurity tasks into five distinct functions.

Which regulatory concept or entity offers guidance and frameworks for this classification?

Answers:

***National Institute of Standards and Technology (NIST)**

General Data Protection Regulation (GDPR)

Payment Card Industry Data Security Standard (PCI DSS)

Center for Internet Security (CIS)

Explanation:

Companies can organize their information security and cybersecurity tasks into the following: identify, protect, detect, respond, and recover. This follows the framework of the National Institute of Standards and Technology.

The General Data Protection Regulation stipulates companies cannot collect, process, or retain personal data without the individual's informed consent.

The Payment Card Industry Data Security Standard defines the safe handling and storage of financial information.

The Center for Internet Securityis a not-for-profit organization founded partly by The SANS Institute. It publishes the 20 CIS Controls.

q_info_class_pii_data_secp8

You are a data analyst at a financial institution. During a routine audit, you discover that a colleague has been storing customers' personally identifiable information (PII) in a non-encrypted, local database for ease of access.

The colleague insists that this practice is safe as the database is password-protected and only accessible from their work computer.

What should you do?

Answers:

Ignore the situation since the database is password-protected and only accessible from your colleague's work computer.

***Report the situation to your supervisor and recommend that the PII data be moved to an encrypted, secure server.**

Confront your colleague and insist that they delete the database immediately.

Access the database yourself to verify the extent of the PII data stored.

Explanation:

Reporting the situation to your supervisor ensures that the issue is handled appropriately and that the PII data is moved to a secure location is the most appropriate action. It also ensures that the company is in compliance with data protection laws and regulations.

Password protection and limited access do not provide sufficient security for PII data. There are still risks such as potential hacking or physical theft of the work computer.

While it's important to address the issue with your colleague, insisting that they delete the database immediately could result in loss of important data. It's better to report the situation to your supervisor who can decide on the best course of action.

Accessing the database yourself could potentially violate privacy policies and regulations. It's best to report the situation to your supervisor and let them handle it.

q_info_class_pii_secp8

If you lose your wallet or purse and it ends up in the wrong hands, several pieces of information could be used to do personal harm to you. These pieces of information include the following:

Name and address

Driver license number

Credit card numbers

Date of birth

Which of the following classifications does this information fall into?

Answers:

***Personally identifiable information**

Proprietary information

Private internal information

Private restricted information

Explanation:

Personally identifiable information (PII) is information that can be used on its own or with other information to identify, contact, or locate a single person. This information includes:

Full name (if not common)

Home address

Email address (if private from an association/club membership, etc.)

National identification number

Passport number

IP address (when linked, but it is not PII by itself in US)

Vehicle registration plate number

Driver's license number

Face, fingerprints, or handwriting

Credit card numbers

Digital identity

Date of birth

Birthplace

Genetic information

Telephone number

Login name, screen name, nickname, or handle

Proprietary information is information that a company wishes to keep confidential. Private internal information is restricted to individuals within the organization and can include personnel records, financial records, and customer lists. Private restricted information is restricted to limited authorized personnel within the organization and can include trade secrets, strategic information, and highly sensitive information.

q_info_class_proprietary_01_secp8

A software company designs a new feature for its product involving the creation and storage of new algorithms and methods that give the product a competitive advantage. The company wants to appropriately classify this information within its data management system.

What would be the MOST fitting classification for this data?

Answers:

Public

Confidential

Critical

***Proprietary**

Explanation:

Proprietary information or intellectual property (IP) refers to information the company creates and owns, typically concerning the products or services it makes or performs.

Public or unclassified data refers to information with no restrictions on viewing and no risk to an organization if someone were to disclose it.

While this data is sensitive, the confidential classification typically applies to information meant for viewing only by approved persons within the organization or by trusted third parties under a non-disclosure agreement.

The term critical generally applies to data or systems whose loss would severely impact the operations or survival of an organization. Although the information is vital to the company, proprietary is more suitable for the information the company owns.

q_info_class_proprietary_02_secp8

A company is very protective of its intellectual material. The fear of a breach by a curious public or competitors is an ongoing concern.

As a result, the company put in place a dedicated server containing related highly sensitive data.

Applying knowledge of data types and labels, which data type is the company is protecting?

Answers:

***Proprietary**

Public

Private

Confidential

Explanation:

Proprietary information, or intellectual property (IP), is information a company creates, typically about the products or services it makes or performs.

Public information bears no classification and has no restrictions on viewing. Companies should be careful not to release information to the public without ensuring the risk of that data.

Classified material (i.e., private, restricted, internal use only, official use only) restricts viewing to the owner organization or third parties under a non-disclosure agreement (NDA).

Confidential (or low) information is a military classification scheme that is highly sensitive and intended for viewing only by approved persons within the organization and possibly by trusted third parties under NDA. However, it may not necessarily be confidential or top secret.

q_info_class_public_01_secp8

A governmental organization is preparing to release census data that includes the total population, age distribution, and employment rates.

According to the data classifications, how should the organization categorize this data?

Answers:

***Public data**

Confidential data

Proprietary data

Restricted data

Explanation:

Public data refers to information that has no restrictions on viewing. The governmental organization's census data, which presents no risk to the organization if disclosed, fits this definition.

Confidential data is highly sensitive and meant for viewing only by approved persons within the organization and possibly by trusted third parties under a non-disclosure agreement (NDA).

Proprietary information or intellectual property is information the company creates and owns, typically about the products or services that it makes or performs.

Restricted data refers to sensitive information that requires stringent controls and limited access due to its highly confidential nature. Restricted data does not fit the description of the census data intended to be publicly released.

q_info_class_public_02_secp8

A national park posts information about its flora and fauna on its website. This information does not contain any personally identifiable information or sensitive government data.

How should the park service classify this data?

Answers:

***Public**

Regulated

Confidential

Private

Explanation:

Public data can include any data that is free to access, such as information about the park's flora and fauna. Likewise, it does not contain any personally identifiable information or sensitive government data.

Regulated data does not encapsulate public data, such as nonsensitive information intended for the public like the park's data.

Confidential data is sensitive information. Data about the park's flora and fauna does not need this type of protection, making this classification inappropriate.

Private classification would require the information about the park's flora and fauna not to be freely available to the public.

q_info_class_readable_secp8

A multinational corporation handles human-readable and non-human-readable data.

What are the implications for security operations and controls?

Answers:

***Security measures for human-readable data: monitoring, user awareness, DLP, and content filtering**

Security measures for human-readable data: monitoring, user awareness, encryption, and secure data exchange

Security measures for non-human-readable data: monitoring, access controls, intrusion detection/prevention, and code/application security

Security measures for non-human-readable data: encryption, access controls, intrusion detection/prevention, and secure data exchange

Explanation:

These measures are directly applicable to protect data formats easily understood and interpreted by humans, such as documents and web pages. Monitoring helps detect and respond to potential threats, while user awareness enhances security practices and data loss prevention (DLP) and content filtering mitigate risks associated with sensitive data.

Encryption and secure data exchange are more relevant to non-human-readable data formats, not human-readable data.

Monitoring is more applicable to human-readable data formats, not non-human-readable data.

Encryption and secure data exchange are relevant to non-human-readable data formats, but access controls and intrusion detection/prevention are also applicable.

q_info_class_regulated_01_secp8

An organization prepares to store and handle a data type that includes sensitive personal information, such as healthcare records and social security numbers. This data is subject to specific laws and regulations concerning its protection and use.

What category does this data type fall under?

Answers:

Trade secrets

Human-readable data

***Regulated data**

Legal and financial data

Explanation:

Regulated data refers to specific categories of information subject to legal or regulatory requirements regarding their handling, storage, and protection, which typically includes sensitive or personally identifiable information (PII), such as healthcare records and social security numbers.

Trade secret data refers to valuable, confidential information that gives a business a competitive advantage.

Human-readable data is information that humans can easily understand and interpret without additional processing or translation.

While this data type is highly sensitive and confidential, it pertains to documents, contracts, financial statements, balance sheets, audit reports, tax records, financial transactions, and other such legal and financial documents.

q_info_class_regulated_02_secp8

The IT department of a healthcare provider maintains a database containing personal health information for its patients.

Which classification BEST suits this type of data?

Answers:

***Regulated**

Critical

Public

Nonsensitive

Explanation:

The classification is that of regulated data since personal health information (PHI) is subject to strict legal and compliance regulations to protect patient privacy, such as Health Insurance Portability and Accountability Act (HIPAA) in the United States.

Critical data could impact the organization's operations or ability to function effectively. While PHI is important, it is not necessarily critical to the survival of the healthcare organization.

Public data is information that the general public can freely disseminate without restrictions. PHI is sensitive and confidential; thus, it cannot be public.

PHI is sensitive and confidential, not public (nonsensitive). Public data is information that is NOT confidential, private, sensitive, regulated, or has any other restrictions.

q_info_class_report_document_secp8

As a cybersecurity analyst at a government agency, you come across a document labeled as "Top Secret Compartmentalized".

You have a Top Secret clearance, but you're not sure if you're authorized to view this document. The document could potentially contain information that would help you resolve a current cybersecurity issue.

What should you do?

Answers:

Open the document. You have Top Secret clearance, so you should be able to view all Top Secret documents.

***Do not open the document. Instead, report the document to your supervisor and ask for guidance.**

Open the document, but only read the sections that you believe are relevant to your current cybersecurity issue.

Ignore the document. If it was meant for you, it would have been sent to you directly.

Explanation:

Report the document to your supervisor to ask for guidance is the most appropriate action to take. You should not access the document without confirming that you are authorized to do so. Reporting the document to your supervisor ensures that you are following protocol and not potentially breaching any security policies.

Even though you have Top Secret clearance, the "Compartmentalized" label means the document has very specific and limited distribution. You should not assume you have access to all Top Secret documents.

Even if you believe the document could be useful, you should not access it without the necessary authorization. Doing so could result in a security breach and potential disciplinary action.

Ignoring the document does not address the potential security issue. It's important to report the document to your supervisor to ensure proper handling.

q_info_class_trade_secret_01_secp8

A tech startup develops a unique algorithm that provides a significant competitive edge in the market. To maintain this edge, the startup needs to ensure the highest level of protection for this information.

How should this startup categorize and handle this unique algorithm?

Answers:

***The startup should categorize the algorithm as a trade secret and protect it using non-disclosure agreements (NDAs).**

The startup should categorize the algorithm as regulated data and follow compliance regulations.

The startup should categorize the algorithm as human-readable data and make it accessible to all employees.

The startup should categorize the algorithm as legal and financial data and keep it secure for financial reporting.

Explanation:

A trade secret is confidential information that gives a business a competitive advantage. The unique algorithm developed by the startup falls into this category. Using non-disclosure agreements can help safeguard the confidentiality of this trade secret.

Regulated data refers to information subject to legal or regulatory requirements regarding handling, storage, and protection, such as personally identifiable information (PII) or health records.

While the algorithm might be human-readable, making it accessible to all employees is not ideal as it increases the risk of leakage or theft.

Legal and financial data relates to critical data for legal compliance, financial reporting, and risk management. While the algorithm might be critical to the startup, it is not considered legal or financial data.

q_info_class_trade_secret_02_secp8

A software development company has just completed an innovative, proprietary software that it plans to release on the market soon. This software includes unique code and intellectual property that they developed in-house and believe is a crucial asset.

What data category does the software's unique code fall under?

Answers:

***Trade secret data**

Regulated data

Legal and financial data

Human-readable data

Explanation:

Trade secrets refer to valuable, confidential information that gives a business a competitive advantage. The unique, proprietary software code developed by the company would fall into this category.

Regulated data usually refers to personal data or data categories directly regulated by laws and regulations, such as financial information or health records. The unique code developed by a software company would not typically fall into this category.

While the company's financials reflect the value of the unique software code, the code itself would not classify as financial or legal data.

Even though software code could technically be human-readable, classifying it as such would not capture the strategic value and need for confidentiality associated with the proprietary software code.

q_info_class_types_secp8

The government and military use the following information classification system:

Unclassified

Sensitive But Unclassified

Confidential

Secret

Top Secret

Drag each classification on the left to the appropriate description on the right.

Answers:

Unclassified

Sensitive But Unclassified

Confidential

Secret

Top Secret

Explanation:

The government and military use the following information classification system:

Unclassified: information that can be accessed by the public and poses no security threat.

Sensitive But Unclassified: information that, if disclosed, could cause some harm but not a national disaster.

Confidential: information that is the lowest level of classified information used by the military. It allows restriction of release under the Freedom of Information Act. Release of this information could cause damage to military efforts.

Secret: information that, if disclosed, could cause severe and permanent damage to military actions.

Top Secret: information that is the highest level of classified information used by the military. If Top Secret information is released, it poses a grave threat to national security.

q_priv_data_resp_controller_secp8

A tech startup is rolling out a new platform that collects user feedback to improve its software. The company manages the data collection, decides how to process it, and has subcontracted a third-party analytics firm to analyze the feedback.

Which role is the startup playing?

Answers:

***Data controller**

Data subject

Data processor

Data custodian

Explanation:

The controller determines the purposes and means of processing personal data. In this case, the startup decides how the data processes and manages its collection, making it the controller.

The data subject is the individual who provides personal data to an organization. In this scenario, the users giving feedback are the data subjects.

The processor processes personal data on behalf of the controller. The third-party analytics firm, which analyzed the feedback, plays this role.

The data custodian is responsible for maintaining and protecting the data. While the startup does handle the data, its primary role is not merely safeguarding it but deciding how to use and process it.

q_priv_data_resp_custodian_secp8

A small department at a company manages a server, separate from IT, for data access and backup purposes.

What role does the department fulfill?

Answers:

***Data custodian**

Data owner

Data controller

Data processor

Explanation:

The data custodian role manages the system on which the data assets reside. This role includes enforcing access control, encryption, and backup/recovery measures.

The data owner is usually in a senior (executive) role with ultimate responsibility for maintaining the information asset's confidentiality, integrity, and availability.

A data controller is responsible for determining why and how employees can collect, keep, and use data and ensuring that these purposes and means are lawful.

A data processor is an entity the data controller engages to assist with technical collection, storage, or analysis tasks.

q_priv_data_resp_data_retention_secp8

A company tasks a data team with decommissioning an organizational data lake.

What are the tenets associated with the data retention concept? (Select the best three options.)

Answers:

***It is often based on legal, regulatory, or operational requirements.**

***It ensures that organizations maintain compliance with relevant regulations and minimize the risk of breaches.**

***It refers to policies and practices governing the storage and preservation of information within the organization for a set period.**

It refers to documenting and verifying the data sanitization or destruction process.

It determines the purposes and means of processing personal data.

It processes personal data on behalf of the data controller.

It provides the right to request access to personal data and obtain information about how it is being processed.

Explanation:

Data retention refers to the policies and practices governing the storage and preservation of information within an organization for a specified period.

In addition, data retention policies are often based on legal, regulatory, or operational requirements and dictate when and how data should be securely deleted or destroyed.

Proper data retention practices ensure that organizations maintain compliance with relevant regulations, optimize storage resources, and minimize the risk of data breaches or unauthorized access to sensitive information during the disposal and decommissioning process.

The following are not tenants associated with the data retention concept:

Certification refers to documenting and verifying the data sanitization or destruction process. It is not part of the data retention concept.

A data controller is the entity or organization that determines the purposes and means of processing personal data.

The data processor processes personal data on behalf of the data controller.

Data subjects hold certain rights. One of these is the right of access, meaning that data subjects have the right to request access to their personal data and obtain information about how it is being processed.

q_priv_data_resp_data_roles_secp8

A healthcare organization is strengthening its data protection framework to ensure compliance with local and international regulations. One focus area is clearly defining the roles and responsibilities between the data controllers and processors, as this impacts the overall management and protection of sensitive data.

In this scenario, which two statements accurately outline the responsibilities of the data controller and the data processor regarding data protection? (Select two.)

Answers:

***Data controller--determines the purposes for which data is processed**

***Data processor--processes data on behalf of the controller**

Data controller--performs day-to-day operations on data

Data processor--decides the purpose of data processing

Both roles have the same responsibilities.

Explanation:

A data controller is primarily responsible for determining the purpose of processing the data, which guides the organization.

On the other hand, the data processor processes the data on behalf of the data controller, following the guidelines the controller provides.

The responsibility of performing day-to-day operations, such as data storage or management, typically falls under the role of the data processor, not the controller.

The data processor does not decide the purpose of data processing. This responsibility belongs to the data controller. The processor operates under the direction of the controller.

The roles in this (and most scenarios) are different, and not the same.

q_priv_data_resp_gdpr_01_secp8

Which of the following accurately reflects the responsibilities of a data processor under data protection laws such as the General Data Protection Regulation (GDPR)?

Answers:

The data processor determines the purposes and means of processing personal data.

The data processor has independent decision-making power over personal data.

The data processor is directly responsible for obtaining consent from data subjects.

***The data processor processes personal data on behalf of the data controller.**

Explanation:

The data processor processes personal data on behalf of the data controller and acts under the authority and instructions of the data controller. The data processor is not allowed to make decisions alone regarding the processing of the data.

The responsibility of determining the purposes and means of processing personal data lies with the data controller, not the data processor.

The data processor does not have independent decision-making power over personal data. The data processor can only process data when the data controller instructs the data processor to do so.

The responsibility of obtaining consent from data subjects lies with the data controller, not the data processor.

q_priv_data_resp_gdpr_02_secp8

Under the General Data Protection Regulation (GDPR), how soon must an organization report a breach of personal data?

Answers:

***Within 72 hours of becoming aware of the breach**

Within 24 hours of becoming aware of the breach

Within 96 hours of becoming aware of the breach

Within 48 hours of becoming aware of the breach

Explanation:

The General Data Protection Regulation (GDPR) requires that an organization must report a breach of personal data to the relevant supervisory authority within 72 hours of discovering it unless the breach is unlikely to risk the rights and freedoms of natural persons.

GDPR requires that organizations must report personal data breaches within 72 hours, not the shorter time frames of 24 or 48 hours.

A time frame of 96 hours is longer than the period specified by GDPR. The regulation stipulates that organizations must report breaches within 72 hours of becoming aware of them. Delaying notification beyond the mandated timeframe could result in penalties.

q_priv_data_resp_gdpr_03_secp8

An organization evaluates the legal implications of failing to protect privacy data after experiencing a breach.

What level of influence does the GDPR have regarding legal implications?

Answers:

***Global**

Regional

National

Local

Explanation:

The General Data Protection Regulation (GDPR) in the European Union has had a substantial impact globally by setting high privacy and data protection standards.

At the regional level, privacy data protections consist of local environments offering regional guidance on data privacy concerns.

At the national level, data protection authorities enforce privacy laws, oversee compliance, and have the authority to investigate data breaches, taking legal action against organizations that fail to protect privacy data or violate individuals' privacy rights.

At the local level, data privacy protection gets limited to smaller areas, enforced only within a confined jurisdiction, and not at regional, national, or global levels.

q_priv_data_resp_gdpr_ccpa_secp8

A multinational firm headquartered in San Francisco, California, serves customers from various countries, including European Union countries.

The company collects, processes, and stores substantial amounts of personal data.

With which of the following legal regulations must the company's governance committee ensure compliance?

Answers:

General Data Protection Regulation (GDPR) only

California Consumer Privacy Act (CCPA) only

***Both General Data Protection Regulation (GDPR) and California Consumer Privacy Act (CCPA)**

Neither General Data Protection Regulation (GDPR) nor California Consumer Privacy Act (CCPA)

Explanation:

GDPR requires companies to protect the personal data and privacy of EU citizens for transactions that occur within the EU. At the same time, CCPA provides California residents with specific rights regarding their personal information.

Although the company serves customers from the European Union and thus needs to comply with the GDPR, it also has its headquarters in California and is subject to the CCPA.

Because the company also serves customers in the European Union, it needs to ensure compliance with the GDPR.

As the company headquarters is in California and serves customers from the European Union, it must comply with both the GDPR and the CCPA; thus, this option is incorrect.

q_priv_data_resp_inventories_01_secp8

When evaluating privacy laws, what provides a comprehensive overview of the types of handled data?

Answers:

***Data inventories**

Data retention

Attestation and acknowledgment

Due diligence

Explanation:

Data inventories provide a comprehensive overview of the types of handled data, the purposes for processing, the legal basis, and the recipients of the data to ensure transparency and accountability.

Data retention is another area impacted by privacy laws. Organizations must retain personal data only for as long as necessary to fulfill the intended purpose or as required by law.

Attestation and acknowledgment require individuals or entities to formally acknowledge their understanding of compliance obligations and commitment to adhere to them through signed agreements, policy acknowledgments, and training activities.

Due diligence in data protection describes the comprehensive assessment and evaluation of an organization's data protection practices and measures.

q_priv_data_resp_inventories_02_secp8

How do data inventories assist organizations in maintaining records of collected data?

Answers:

***It provides a comprehensive overview of the types of handled data.**

It is an established timeline that requires organizations to keep documentation.

It requires individuals or entities to announce their understanding of compliance obligations formally.

It is the comprehensive assessment and evaluation of an organization's data protection practices.

Explanation:

Data inventories provide a comprehensive overview of the types of handled data, the purposes for processing, the legal basis, and the recipients of the data to ensure transparency and accountability.

Data retention is another area impacted by privacy laws. Organizations must retain personal data only for as long as necessary to fulfill the intended purpose or as required by law.

Attestation and acknowledgment require individuals or entities to formally acknowledge their understanding of compliance obligations and commitment to adhere to them through signed agreements, policy acknowledgments, and training activities.

Due diligence in data protection describes the comprehensive assessment and evaluation of an organization's data protection practices and measures.

q_priv_data_resp_owner_secp8

You are the data privacy officer (DPO) at a large corporation.

A new project involving the processing of personal data is about to start. The project manager approaches you for guidance on roles and responsibilities related to data privacy.

Which of the following advice would be MOST appropriate to give?

Answers:

The project manager should act as the data owner, controller, and processor.

***The project manager should act as the data owner, and appoint separate individuals as the data controller and processor.**

The project manager should act as the data controller, and appoint separate individuals as the data owner and processor.

The project manager should act as the data processor, and appoint separate individuals as the data owner and controller.

Explanation:

The project manager should act as the data owner, and appoint separate individuals as the data controller and processor is the correct answer. The data owner is usually a senior stakeholder responsible for a dataset. The data controller and processor should be separate individuals to ensure checks and balances. The controller decides the purpose and procedure for processing personal data, while the processor carries out the daily processing of personal data.

The project manager should act as the data owner, controller, and processor is not correct. It is not advisable for one person to take on all these roles as it could lead to conflicts of interest and potential breaches in data privacy.

The project manager should act as the data controller, and appoint separate individuals as the data owner and processor is not correct. The project manager, who is overseeing the project, would be more suited to the role of data owner. The roles of data controller and processor should be assigned to individuals who are involved in the daily handling and processing of data.

The project manager should act as the data processor, and appoint separate individuals as the data owner and controller is not correct. The project manager, given their seniority and oversight role, would be more suited to the role of data owner. The roles of data controller and processor should be assigned to individuals who are involved in the daily handling and processing of data.

q_priv_data_resp_right_forgotten_secp8

A healthcare provider must maintain comprehensive patient records while ensuring the privacy of individuals' information.

How can the provider navigate legal requirements for data retention with respect to patients who request that their information is removable?

Answers:

Establishing a specific data retention policy

Maintaining extended data inventory

***Complying with the right to be forgotten**

Regularly reviewing and updating privacy policies

Explanation:

Involving procedures that enable patients to request the deletion of their data, complying with the right to be forgotten requires the healthcare provider to evaluate whether these requests align with the current legal framework.

Separate from individuals' rights to control their personal information, establishing a specific data retention policy presents its own different considerations.

While maintaining an extended data inventory can aid in complying with various regulations, it does not address how organizations should handle patient requests for data removal.

Regularly reviewing and updating privacy policies focuses on ensuring legal compliance rather than serving as a solution to conflicts between legal retention obligations and individual data removal requests.

q_priv_data_resp_roles_secp8

Security governance relies heavily on specially designed and interdependent roles. Each role has unique responsibilities that contribute to effective security oversight and control.

What are some of these roles? (Select three.)

Answers:

***Owner**

***Controller**

***Processor**

Maintenance custodian

Administrator

Engineer

Technician

Explanation:

A high-ranking employee (i.e., a director or vice president) typically holds the owner role and is ultimately responsible for ensuring data is appropriately protected.

The controller role closely relates to the General Data Protection Regulation (GDPR) and identifies the purposes, conditions, and means of processing personal data.

The processor is responsible for processing personal data on behalf of the controller and often represents Cloud Service Providers (CSP), although they could also be vendors and business partners.

The following are NOT security governance roles:

A maintenance custodian performs the upkeep and care of a building and is responsible for its cleanup. On the other hand, a security governance custodian is responsible for the safe custody, transport, and storage of the data. They are two entirely different roles.

Administrator, engineer, and technician are networking roles.

q_priv_data_scenario_secp8

You are a data protection officer at a tech company. The company is planning to launch a new product that collects user data for personalized recommendations. The data collected includes user names, addresses, contact information, and their browsing history on the company's platform.

Which of the following statements BEST describes how the company should handle this data?

Answers:

The company should treat all collected data as confidential data since it is collected for business purposes.

The company should treat all collected data as privacy data since it can be used to identify specific individuals.

***The company should treat user names, addresses, and contact information as privacy data, and browsing history as confidential data.**

The company should not differentiate between privacy data and confidential data and should apply the same protection measures to all collected data.

Explanation:

User names, addresses, and contact information are privacy data as they can be used to identify specific individuals. Browsing history on the company's platform is considered confidential data as it pertains to the company's proprietary information is the correct answer.

While the data is collected for business purposes, it includes personally identifiable information (PII) such as user names, addresses, and contact information, which should be treated as privacy data.

While user names, addresses, and contact information are privacy data, browsing history on the company's platform is considered confidential data as it pertains to the company's proprietary information.

Privacy data and confidential data have different legal and ethical considerations. Privacy data pertains to personal information and individual privacy rights, while confidential data is concerned with safeguarding information from unauthorized access, use, or disclosure to maintain business competitiveness and protect intellectual property. Therefore, different protection measures should be applied to each type of data.

q_data_destroy_facts_certificate_01_secp8

A healthcare organization is preparing to decommission several servers containing sensitive patient information. The organization wants to ensure that it securely disposes of the data on these servers and properly documents this process.

What should the organization primarily focus on to ensure secure data disposal and regulation compliance?

Answers:

***Obtain a certificate of destruction or sanitization from a third-party provider.**

Sell the servers as soon as possible to reclaim some of the initial investment.

Keep the servers in storage indefinitely as a backup in case of data loss.

Pass the servers to the IT team for random allocation among employees.

Explanation:

Obtaining certification proves that the organization securely eliminated data in compliance with industry standards and regulations. It also reduces the risk of legal liabilities and serves as evidence of due diligence.

Failing to ensure the secure destruction of the sensitive data before selling the servers could lead to serious data breaches and regulatory noncompliance.

Keeping the servers in storage indefinitely could increase the risk of a data breach over time and unnecessarily ties up storage space that could have better uses.

This action does not address the primary issue of securely destroying sensitive data. It also creates potential security risks, as employees could access or misuse sensitive data.

q_data_destroy_facts_certificate_02_secp8

A security specialist is drafting a memorandum on secure data destruction for the organization after a recent breach.

What benefit does the certification concept offer when evaluating appropriate disposal/decommissioning?

Answers:

***It refers to the documentation and verification of the data sanitization or destruction process.**

It refers to policies and practices governing the storage and preservation of information within the organization for a set period of time.

It is often based on legal, regulatory, or operational requirements.

It ensures that organizations maintain compliance with relevant regulations and minimize breach risks.

Explanation:

Certification refers to documenting and verifying the data sanitization or destruction process.

Data retention, not certification, refers to the policies and practices governing the storage and preservation of information within an organization for a specified period.

Data retention policies are often based on legal, regulatory, or operational requirements and dictate when and how organizations should securely delete or destroy data.

Proper data retention practices ensure that organizations maintain compliance with relevant regulations, optimize storage resources, and minimize the risk of data breaches or unauthorized access to sensitive information during the disposal and decommissioning process.

q_data_destroy_facts_combo_secp8

You are a cybersecurity expert at a large corporation. Your company has just decommissioned a data center and you are tasked with ensuring the secure destruction of data on thousands of hard drives. The data includes highly sensitive information.

Which of the following solutions would be BEST for destroying the data?

Answers:

Overwrite the data on the drives and then reuse them within the company.

Use a third-party service to degauss the drives.

Physically destroy the drives by pulverizing them.

***Use a combination of overwriting and degaussing before disposing of the drives.**

Explanation:

Using a combination of overwriting and degaussing before disposing of the drives is the best solution in this scenario. This option provides a high level of security by first overwriting the data (making it unreadable) and then degaussing the drives (rendering them unusable). This two-step process reduces the chance of data recovery to near zero. While the drives cannot be reused, the level of data sensitivity and the scale of the task may warrant this approach.

While overwriting the data can make it unreadable and allows for the medium to be reused, it may not be the most secure method for highly sensitive data. There's a small chance that some data could potentially be recovered.

Degaussing changes the magnetic field of the drive, rendering it unusable and the data unrecoverable. This is a secure method of data destruction for highly sensitive data. However, it means the drives cannot be reused, which could be a waste of resources given the large number of drives.

While physically destroy the drives by pulverizing them would ensure the data is unrecoverable, it is not the most environmentally friendly option. It also doesn't allow for the possibility of reusing or recycling the drives.

q_data_destroy_facts_decomission_secp8

In preparation for taking over inventory for their division, an engineer reviews the records for the previous inventory count. The engineer notes that a few items were on the previous inventory count that they could not find during their initial search.

What records should they review prior to looking for the missing items?

Answers:

***Decommissioning**

Access control

Configuration enforcement

Monitoring

Explanation:

The final step in the decommissioning process involves updating inventory records to reflect decommissioned devices. The decommissioning records explain why the property was on the previous inventory.

Access control relates to permissions granted to individuals, software, networks, or systems to only allow the completion of authorized actions by these entries. It is not a part of the inventory process.

Configuration enforcement ensures that systems and devices within a network have the same configuration, allowing for easier identification of compromised systems. It is not a part of the inventory process.

Monitoring plays a vital role in the hardening process. Additionally, it can provide valuable data for compliance and auditing purposes. It is not a part of the inventory process.

q_data_destroy_facts_degaus_01_secp8

Which of the following is the LEAST reliable means of cleaning or purging media?

Answers:

OS low-level formatting

***Degaussing**

Overwriting every sector with alternating 1s and 0s

Drive controller hardware-level formatting

Explanation:

The least reliable means to clean or purge media is degaussing. Degaussing is the use of strong magnetic fields to remove stored information from a drive. Unfortunately, user error and equipment failure often results in only partially cleaned media.

Various forms of formatting (such as OS low-level formatting and drive controller hardware-level formatting) are not perfect, but they are often more reliable than degaussing. Overwriting every sector with alternating 1s and 0s can be effective if performed multiple times (such as 60 or more).

q_data_destroy_facts_degaus_02_secp8

You are the head of the IT department at a large corporation. Your company has just completed a major data migration project and you now have a significant number of old hard drives that contain sensitive company data. You need to ensure this data is completely destroyed to prevent any potential data breaches.

Which method would you choose and why?

Answers:

Overwrite the data on the drives and then reuse them within the company.

***Use a third-party service to degauss the drives.**

Physically destroy the drives by pulverizing them.

Overwrite the data on the drives and then sell them to a recycling company.

Explanation:

Use a third-party service to degauss the drives is the correct answer. Degaussing changes the magnetic field of the drive, rendering it unusable and the data unrecoverable. This is a secure method of data destruction for highly sensitive data. However, it means the drives cannot be reused.

While overwriting the data can make it unreadable and allows for the medium to be reused, it may not be the most secure method for highly sensitive data. There's a small chance that some data could potentially be recovered.

While physically destroying the drives would ensure the data is unrecoverable, it is not the most environmentally friendly option. It also doesn't allow for the possibility of reusing or recycling the drives.

Overwriting the data on the drives and then selling them to a recycling company has the same potential security issue as option A. Additionally, selling the drives to a third party, even a recycling company, could potentially expose the company to a data breach if the overwriting process was not 100% effective.

q_data_destroy_facts_degaus_03_secp8

A financial services company is decommissioning many servers that contain highly sensitive financial information. The company's data protection policy stipulates the need to use the MOST secure data destruction methods and comply with strict regulatory requirements.

The company also has a significant environmental sustainability commitment and seeks to minimize waste wherever possible.

What should the company's primary course of action be during this process?

Answers:

***Degaussing the servers, rendering the data irretrievable, followed by reselling or recycling the servers after certification**

Incinerating the servers, as it's the most effective method of data destruction

Overwriting the data on the servers multiple times, then disposing of the servers without any certification

Storing the servers indefinitely in a secure location to avoid any risk of data leakage

Explanation:

This method would ensure the secure destruction of sensitive data and compliance with regulatory requirements. Also, the company can uphold its environmental sustainability commitment by reselling or recycling.

Incinerating the servers is an effective data destruction method, but it would not align with the company's commitment to environmental sustainability. Additionally, it may not be the most cost-effective solution, especially if the servers are repurposeable or recyclable.

Overwriting the data on the servers multiple times, then disposing of the servers without certification would not meet strict regulatory requirements.

Storing the servers indefinitely in a secure location would be inefficient and unnecessary. This method would occupy physical space and resources indefinitely and pose a constant risk of potential data breaches.

q_data_destroy_facts_destruction_01_secp8

When cleaning out the server closet, a company discovers a box of old disk drives.

When considering which disposal method to use, what are the characteristics associated with the destruction concept? (Select two.)

Answers:

***It involves the physical or electronic elimination of information stored on media, rendering it inaccessible and irrecoverable.**

***Its methods include shredding, crushing, or incinerating storage devices.**

It refers to removing sensitive information from storage media to prevent unauthorized access or data breaches.

Its process uses specialized techniques, such as data wiping, degaussing, or encryption.

It refers to copying files to other media to keep in a secure safe.

Explanation:

Destruction involves the physical or electronic elimination of information stored in media, rendering it inaccessible and irrecoverable.

Destruction methods include shredding, crushing, or incinerating storage devices, while electronic destruction involves overwriting data multiple times or using degaussing techniques to eliminate magnetic fields on storage media.

Sanitization refers to removing sensitive information from storage media to prevent unauthorized access or data breaches.

Sanitization uses specialized techniques, such as data wiping, degaussing, or encryption, to ensure the data becomes irretrievable. Sanitization is particularly important when repurposing or donating storage devices.

Copying the files to other media to keep in a secure safe is not a key concept of destruction.

q_data_destroy_facts_destruction_02_secp8

A healthcare organization is retiring an old database server that housed sensitive patient information. It aims to ensure that this information is completely irretrievable.

What key process should the organization prioritize before disposing of this server?

Answers:

***Secure destruction of all data stored on the server**

Certification of the server's functionality

Preservation of all data for future reference

Repurposing of the server without any modifications

Explanation:

Secure destruction involves the physical or electronic elimination of information stored on media, rendering it inaccessible and irrecoverable. It is a crucial step before disposing of any storage devices containing sensitive information.

Certification is important, but it usually refers to documenting and verifying the data sanitization or destruction process. In this context, it is not the initial step before disposal.

Preserving sensitive data when a storage device decommissions increases the risk of data breaches and non-compliance with data protection regulations.

Repurposing storage devices without first sanitizing them could lead to unauthorized access to sensitive information. In this context, the organization must destroy the data before the disposal or repurposing of a server.

q_data_destroy_facts_destruction_03_secp8

An organization has decommissioned several laptops used for handling sensitive data.

Which of the following should be the primary step to ensure data security and compliance with regulations before repurposing or disposing of these devices?

Answers:

Conducting a hardware audit

Removing all software applications

Deleting all user accounts

***Initiating a secure data destruction process**

Explanation:

Initiating a secure data destruction process ensures the irretrievable deletion of sensitive data on the laptops' storage media, preventing unauthorized access or data breaches.

Conducting a hardware audit is an important part of asset management and could be useful in tracking the decommissioned laptops. However, it does not directly ensure the security of the sensitive data previously stored on the devices.

Removing all software applications from the laptops could make some data less accessible, but it will not ensure the secure deletion of sensitive data.

Deleting all user accounts can remove some user-specific data and settings from the laptops but will not securely delete or sanitize all the sensitive data stored on the devices.

q_data_destroy_facts_pulv_01_secp8

When you dispose of a computer or sell used hardware, it is crucial that none of the data on the hard disks can be recovered.

Which of the following actions can you take to ensure that no data is recoverable?

Answers:

***Damage the hard disks so badly that all data remanence is gone.**

Reformat all the hard disks in the computer.

Delete all files from all the hard disks in the computer.

Encrypt all data on the hard disks.

Explanation:

When you dispose of a computer, sell used hardware, or erase important information, it's crucial to destroy all of the data on a device. It's not enough to delete the data. Reformatting the hard drive is also not sufficient. If other people can access the computer, they can use data remanence (the residual representation of erased data) to recover information. You must damage the hardware so badly that the remanence is gone.

q_data_destroy_facts_pulv_02_secp8

Which of the following data destruction techniques uses a punch press or hammer system to crush a hard disk?

Answers:

***Pulverizing**

Shredding

Pulping

Purging

Degaussing

Explanation:

The following are various ways to destroy data:

Pulverizing: like shredding except that it uses a punch press or hammer system to crush a hard disk into a pile of metal confetti.

Burning: the method of building a small fire somewhere legal and safe. Use metal tongs to burn your documents one by one or a few at a time. It's important to ensure that each document is turned into ash. If sensitive information escapes the flames and flies away, it might fall into the wrong hands.

Shredding: running a hard disk through a disk shredder, physically destroying the drive.

Pulping: a way of removing all traces of ink from paper by using chemicals and then mashing the paper into pulp. Since these chemicals can ruin carpet and clothing, you should perform this process outside and use protective gloves.

Degaussing: purges the hard disk by exposing it to a high magnetic pulse that destroys all of the data on the disk. This also ruins the motors inside the drive.

Purging: the removal of sensitive data, ensuring that it cannot be reconstructed by any known technique.

Wiping: a software-based method of overwriting data to completely destroy all electronic data residing on a hard disk drive or other digital media. Wiping uses 0s and 1s to overwrite data onto all sectors of the device. The data is rendered unrecoverable and achieves data sanitization.

q_data_destroy_facts_sanitize_01_secp8

A tech company is in the process of decommissioning a fleet of old servers. It wants to ensure that sensitive data stored on these servers is fully eliminated and are not accesible in the event of unauthorized attempts.

What primary process should the company implement before disposing or repurposing these servers?

Answers:

***Sanitizing the servers**

Deleting all the files on the servers

Moving the servers to a secure storage location

Selling the servers immediately

Explanation:

Sanitizing the servers uses specialized techniques, such as data wiping, degaussing, or encryption, to ensure the data becomes irretrievable.

Deleting all files on the servers is ineffective because deleting files from a magnetic-type hard disk does not fully erase them.

Moving the servers to a secure location and keeping them untouched does not address the need to remove sensitive data from the servers. If someone accesses the servers without authorization, it would increase the data breach risk.

Selling the servers immediately without considering the stored data is risky as it could lead to unauthorized access to sensitive data, legal liabilities, and reputational damage.

q_data_destroy_facts_sanitize_02_secp8

A financial institution is preparing to decommission a number of its old servers. The servers contain sensitive customer data that needs proper handling to prevent unauthorized access or data breaches.

Which strategy should the institution primarily employ to ensure the data on these servers stays irretrievable?

Answers:

***Carry out a sanitization process that includes multiple passes of overwriting and degaussing.**

Leave the data on the servers, as the system will eventually overwrite it.

Use a basic method of overwriting, such as zero filling, once.

Physically destroying the servers is necessary.

Explanation:

The sanitization process ensures that the data on the servers is irretrievable, protecting sensitive customer data from unauthorized access or data breaches.

Leaving the data on the servers until it eventually overwrites would not be a secure option. This approach would leave the data vulnerable to unauthorized access or data breaches.

Single-pass zero filling can leave patterns readable with specialist tools, so multiple passes become necessary for proper sanitization.

Physically destroying the servers without considering any data wiping process could leave data accessible. Physical destruction should be a final step after the company thoroughly sanitizes the data electronically.

q_data_destroy_facts_sanitize_03_secp8

Upon receiving new storage media drives for the department, an organization asks a software engineer to dispose of the old drives.

When considering the various methods, what processes does sanitization involve? (Select two.)

Answers:

***It refers to the process of removing sensitive information from storage media to prevent unauthorized access or data breaches.**

***Its process uses specialized techniques, such as data wiping, degaussing, or encryption.**

It involves the physical or electronic elimination of information stored in media, rendering it inaccessible and irrecoverable.

Its methods include shredding, crushing, or incinerating storage devices.

It involves the documentation and verification of the destruction process.

Explanation:

Sanitization refers to removing sensitive information from storage media to prevent unauthorized access or data breaches.

Sanitization uses specialized techniques, such as data wiping, degaussing, or encryption, to ensure the data becomes irretrievable. Sanitization is particularly important when repurposing or donating storage devices.

Destruction involves the physical or electronic elimination of information stored in media, rendering it inaccessible and irrecoverable.

Destruction methods include shredding, crushing, or incinerating storage devices, while electronic destruction involves overwriting data multiple times or using degaussing techniques to eliminate magnetic fields on storage media.

Certification refers to the documentation and verification of the data sanitization or destruction process.

13.2 Personnel Policies

As you study this section, answer the following questions:

How can an onboarding process improve the security of an organization?

Why should employees be required to sign employment agreements?

Why is it important to conduct an exit interview?

What security issues must be identified and addressed during the onboarding phase of a third-party relationship?

What is the role of the Service Level Agreement (SLA)?

Why are policies important for organizational security?

The key terms for this section include:

Term	Definition
Onboarding	The process of bringing in a new employee, contractor, or supplier.
Offboarding	The process of ensuring that all HR and other requirements are covered when an employee leaves an organization.
Acceptable use policy (AUP)	A policy that governs employees' use of company equipment and Internet services. ISPs may also apply AUPs to their customers.

Code of conduct	Professional behavior depends on basic ethical standards, such as honesty and fairness. Some professions may have developed codes of ethics to cover difficult situations; some businesses may also have a code of ethics to communicate the values it expects its employees to practice.
Clean desk policy	An organizational policy that mandates employee work areas be free from potentially sensitive information; sensitive documents must not be left out where unauthorized personnel might see them.
Computer-based training (CBT)	Training and education programs delivered using computer devices and e-learning instructional models and design.
Anomalous behavior recognition	Systems that automatically detect users, hosts, and services that deviate from what is expected, or systems and training that encourage reporting of this by employees.
Database encryption	Applying encryption at the table, field, or record level via a database management system rather than via the file system.
Data sovereignty	In data protection, the principle that countries and states may impose individual requirements on data collected or stored within their jurisdiction.

This section helps you prepare for the following certification exam objectives:

Exam	Objective
CompTIA Security+ SY0-701	2.5 Explain the purpose of mitigation techniques used to secure the enterprise. Least privilege 3.3 Compare and contrast concepts and strategies to protect data. Data types Regulated Intellectual property Legal information Financial information Data classifications General data considerations

Data states

Data at rest

Data in transit

Data in use

Data sovereignty

Geolocation

Methods to secure data

Encryption

4.1 Given a scenario, apply common security techniques to computing resources.

Mobile solutions

Bring your own device (BYOD)

4.2 Explain the security implications of proper hardware, software, and data asset management.

Disposal/decommissioning

Data retention 4.4 Explain security alerting and monitoring concepts and tools.

Tools

Data loss prevention (DLP)

4.6 Given a scenario, implement and maintain identity and access management.

Access controls

Least privilege

4.8 Explain appropriate incident response activities.

Training

Digital forensics

Legal hold

5.1 Summarize elements of effective security governance.

	Policies Acceptable use policy (AUP) Procedures Onboarding/offboarding 5.4 Summarize elements of effective security compliance. Privacy Legal implications Data inventory and retention 5.6 Given a scenario, implement security awareness practices. TestOut Security Pro	5.0 Audit and Security Assessment

13.2.1 Personnel Policies (Lesson Video)

Transcript:

In this lesson, we're going to discuss personnel policies. Employees are a critical part of any successful business, but they also represent one of the greatest risks to your organization's security. Using proper employment practices helps mitigate this risk. They should encompass all aspects of employment, from pre-employment screenings to offboarding.

Employee security should start even before an employee starts work. To ensure that a potential employee is a low security risk, an organization should perform a background check. This check may include checking into a person's criminal history, credit history, and employment history. It could also involve drug testing, identity verification, or a review of their social media presence.
Once you've decided to hire an individual, you'll need to set up a work environment for them. This process is called onboarding. It primarily involves a lot of HR paperwork, but there are a few onboarding procedures that involve security professionals.
When you're setting up the new employee's user accounts, security credentials, and building access, make sure to assign the appropriate access rights. To do this, you'll need to know the new employee's job title, duties, and place in the organizational hierarchy.
It's also important that new employees sign necessary forms and documents. A non-disclosure agreement stipulates that employees can't reveal confidential or proprietary information to any non-employee. A non-compete agreement prevents former employees from working for competitors. And an acceptable use policy specifies how employees are allowed to use the information organization's network resources.
As we've discussed, employees are a serious security risk. Sometimes they're intentionally trying to cause harm, but more often, they're simply uninformed. One way to help secure your data and your network is to hold regular security trainings for your employees. These trainings should include topics like how to recognize security breaches and exploits when they occur, what to do in the event of a security breach, and sample scenarios with recommended responses.
Training should be ongoing and train employees on new security issues and refresh them on older topics. Ideally, you should use a combination of teaching techniques so you have a better chance of engaging everyone and helping them retain information.
In addition to classroom training, security methods can be taught through games, simulations, role-based hands-on training, or computer-based training.
Onboarding and training provide a great starting point, but you still need ongoing policies to ensure that employee performance and duties are secure.
So, how can we better secure our daily operations? First, let's look at separation of duties. Separation of duties restricts the amount of access or influence individuals control, which removes single points of failure within the organization.
For example, let's say an employee in accounting approves business expenses, verifies expenditures, signs checks, and withdraws funds. The risk of this employee embezzling company money is significantly multiplied because this one person performs all of these duties. In this situation, this person could easily become a single point of failure.
With separation of duties, expenditures and withdrawals should be verified by at least two sets of people. And maybe the CFO should sign the checks instead of the accountant. This way, we can eliminate this single point of failure.
You can also enhance security by implementing duty rotations. For example, after a couple of months, each person's responsibility shifts to another person, like a chore chart.
So, using our previous example, instead of signing checks, the CFO verifies and approves expenditures, while others handle withdrawals and signing checks. Duty rotations also heighten security by continually monitoring accountability during the rotation process.
Now let's move on to the principle of least privilege. The idea behind this principle is that employees only have access to information they absolutely need for their job function. Employees with too much access could either intentionally or unintentionally compromise security.
For example, administrative accounts should only be given to people who need them, and this access should only be used by employees who are actively performing administrative duties. A best practice is to log in with a standard user account and then only change to an administrative account to perform a task that requires it. When you're done with that task, you switch back to the standard user account.

It's never a good idea to be logged in as an administrator while browsing the web, reading emails, or using social media. An exploit coming through that internet connection could easily obtain elevated privileges on that workstation, which hugely increases the potential for damages.
Another practice to increase security is a mandatory vacation policy. The best way to implement mandatory vacations is to require employees to request vacation days in advance, like at the beginning of the year. The benefits of mandatory vacations are twofold. First, they allow employees to take a break from work, rest, and recharge. Second, they provide the security administrator the ability to detect fraudulent activities while employees are away. For example, if you notice that a reoccurring security breach stops while a particular employee is away on vacation, that could help you identify its cause.
The last step in employment is offboarding. Whether an employee resigns, retires, or is terminated, offboarding procedures keep the company safe as they depart.
First, you should disable or delete that employee's user account. An active, unused account allows easy access to your network. When you delete a user account, be sure not to delete that user's data in the process. Make sure their files are preserved. You want that data available for future use. So you may want to disable former employees' accounts rather than delete them.
You should also change security keys and require the return of access tokens, devices, and phones. And when an employee leaves the organization, Human Resources should always conduct an exit interview.
During this interview, it's important to address any concerns, dissatisfactions, or feedback from the employee. With this information, you'll have a better idea of why the employee is leaving and be able to address any remaining concerns. This is also a good time to remind the employee of any non-disclosure or non-compete agreements they may have signed during their onboarding process.
That's it for this lesson. In this lesson, we discussed the importance of personnel policies during the pre-employment process, onboarding, training, and daily operations, and we finished by discussing offboarding policies that protect the company and mitigate risks.

13.2.2 Personnel Policy Facts

Personnel policies play a vital role in establishing clear guidelines, expectations, and standards for employees. They provide a framework for effective management of human resources and maintain a fair, legally compliant, and productive work environment. Personnel policies promote consistency, clear communication, employee development, conflict resolution, and risk management. Organizations can enhance employee satisfaction, attract and retain talent, and mitigate legal and operational risks by implementing effective personnel policies.

This lesson covers the following topics:

- Personnel Management
- Conduct policies
- Training topics and techniques
- Reporting and monitoring

Personnel Management

Human Resources (HR) policies for personnel management are applied in three phases:

- **Recruitment (hiring)** — locating and selecting people to work in particular job roles. Security issues here include screening candidates and performing background checks.
- **Operation (working)** — it is often the HR department that manages the communication of policy and training to employees (though there may be a separate training and personal development department within larger organizations). As such, it is critical that HR managers devise training programs that communicate the importance of security to employees.

Termination or Separation (firing or retiring) — whether an employee leaves voluntarily or involuntarily, termination is a difficult process, with numerous security implications.

Background Checks

A background check determines that a person is who they say they are and are not concealing criminal activity, bankruptcy, or connections that would make them unsuitable or risky. Employees working in high confidentiality environments or with access to high-value transactions will obviously need to be subjected to a greater degree of scrutiny. For some jobs, especially federal jobs requiring a security clearance, background checks are mandatory. Some background checks are performed internally, whereas others are done by an external third party.

Onboarding

Onboarding at the HR level is the process of welcoming a new employee to the organization. The same sort of principle applies to taking on new suppliers or contractors. Some of the same checks and processes are used in creating customer and guest accounts.

As part of onboarding, the IT and HR function will combine to create an account for the user to access the computer system, assign the appropriate privileges, and ensure the account credentials are known only to the valid user. These functions must be integrated, to avoid creating accidental configuration vulnerabilities, such as IT creating an account for an employee who is never actually hired. Some of the other tasks and processes involved in onboarding include the following:

Secure Transmission of Credentials — creating and sending an initial password or issuing a smart card securely. The process needs protection against rogue administrative staff. Newly created accounts with simple or default passwords are an easily exploitable backdoor.

Asset Allocation — provision computers or mobile devices for the user or agree to the use of bring-your-own-device handsets.

Training/Policies — schedule appropriate security awareness and role-relevant training and certification.

Offboarding

An exit interview (or offboarding) is the process of ensuring that an employee leaves a company gracefully. Offboarding is also used when a project using contractors or third parties ends. In terms of security, there are several processes that must be completed:

Account Management — disable the user account and privileges. Ensure that any information assets created or managed by the employee but owned by the company are accessible (in terms of encryption keys or password-protected files).

Company Assets — retrieve mobile devices, keys, smart cards, USB media, and so on. The employee will need to confirm (and in some cases prove) that they have not retained copies of any information assets.

Personal Assets — wipe employee-owned devices of corporate data and applications. The employee may also be allowed to retain some information assets (such as personal emails or contact information), depending on the policies in force.

The departure of some types of employees should trigger additional processes to re-secure network systems. Examples include employees with detailed knowledge of security systems and procedures, and access to shared or generic account credentials. These credentials must be changed immediately.

Conduct Policies

Operational policies include privilege/credential management, data handling, and incident response. Other important security policies include those governing employee conduct and respect for privacy.

Acceptable Use Policy

Enforcing an acceptable use policy (AUP) is important to protect the organization from the security and legal implications of employees misusing its equipment. Typically, the policy will forbid the use of equipment to defraud, defame, or to obtain illegal material. It will prohibit the installation of unauthorized hardware or software and explicitly forbid actual or attempted snooping of confidential data that the employee is not authorized to access. Acceptable use guidelines must be reasonable and not interfere with employees' fundamental job duties or privacy rights. An organization's AUP may forbid use of Internet tools outside of work-related duties or restrict such use to break times.

Code of Conduct and Social Media Analysis

A code of conduct , or rules of behavior, sets out expected professional standards. For example, employees' use of social media and file sharing poses substantial risks to the organization, including threat of virus infection or systems intrusion, lost work time, copyright infringement, and defamation. Users should be aware that any data communications, such as email, made through an organization's computer system are likely stored within the system, on servers, backup devices, and so on. Such communications are also likely to be logged and monitored. Employers may also subject employees' personal social media accounts to analysis and monitoring, to check for policy infringements.

Rules of behavior are also important when considering employees with privileged access to computer systems. Technicians and managers should be bound by clauses that forbid them from misusing privileges to snoop on other employees or to disable a security mechanism.

Use of Personally Owned Devices in the Workplace

Portable devices, such as smartphones, USB sticks, media players, and so on, pose a considerable threat to data security, as they make file copy so easy. Camera and voice-recording functions are other obvious security issues. Network access control, endpoint management, and data loss prevention solutions can be of some use in preventing the attachment of such devices to corporate networks. Some companies may try to prevent staff from bringing such devices on-site . This is quite difficult to enforce, though.

Also important to consider is the unauthorized use of personal software by employees or employees using software or services that has not been sanctioned for a project (shadow IT). Personal software may include either locally installed software or hosted applications, such as personal email or instant messenger, and may leave the organization open to a variety of security vulnerabilities. Such programs may provide a route for data exfiltration, a transport mechanism for malware, or possibly software license violations for which the company might be held liable, just to name a few of the potential problems.

Clean Desk Policy

A clean desk policy means that each employee's work area should be free from any documents left there. The aim of the policy is to prevent sensitive information from being obtained by unauthorized staff or guests at the workplace.

Training Topics and Techniques

It is necessary to frame security training in language that end users will respond to. Education should focus on responsibilities and threats that are relevant to users. It is necessary to educate users about new or emerging threats (such as fileless malware, phishing scams, or zero-day exploits in software), but this needs to be stated in language that users understand. Using a diversity of training techniques helps to improve engagement and retention. Training methods include facilitated workshops and events,

one-on-one instruction and mentoring, plus resources such as computer-based or online training, videos, books, and blogs/newsletters.

User and Role-Based Training

Another essential component of a secure system is effective user training. Untrained users represent a serious vulnerability because they are susceptible to social engineering and malware attacks and may be careless when handling sensitive or confidential data.

Train users in secure behavior. (Image by dotshock © 123RF.com.)

Appropriate security awareness training needs to be delivered to employees at all levels, including end users, technical staff, and executives. Some of the general topics that need to be covered include the following:

- Overview of the organization's security policies and the penalties for noncompliance.
- Incident identification and reporting procedures.
- Site security procedures, restrictions, and advice, including safety drills, escorting guests, use of secure areas, and use of personal devices.
- Data handling, including document confidentiality, PII, backup, encryption, and so on.
- Password and account management plus security features of PCs and mobile devices.
- Awareness of social engineering and malware threats, including phishing, website exploits, and spam plus alerting methods for new threats.
- Secure use of software such as browsers and email clients plus appropriate use of Internet access, including social networking sites.

There should also be a system for identifying staff performing security-sensitive roles and grading the level of training and education required (between beginner, intermediate, and advanced, for instance). Note that in defining such training programs you need to focus on job roles, rather than job titles, as employees may perform different roles and have different security training, education, or awareness requirements in each role.

The NIST National Initiative for Cybersecurity Education framework (nist.gov/itl/applied-cybersecurity/nice) sets out knowledge, skills, and abilities (KSAs) for different cybersecurity roles. Security awareness programs are described in SP800-50 (nvlpubs.nist.gov/nistpubs/Legacy/SP/nistspecialpublication800-50.pdf).

Computer-Based Training and Gamification

Participants respond well to the competitive challenge of CTF events. This type of gamification can be used to boost security awareness for other roles too. Computer-based training (CBT) allows a student to acquire skills and experience by completing various types of practical activities:

Simulations — recreating system interfaces or using emulators so students can practice configuration tasks.

Branching scenarios — having students choose between options to find the best choices to solve a cybersecurity incident or configuration problem.

CBT might use video game elements to improve engagement. For example, students might win badges and level-up bonuses such as skills or digitized loot to improve their in-game avatar. Simulations might be presented so that the student chooses encounters from a map and engages with a simulation environment in a first person shooter type of 3D world.

Critical Elements for Security Awareness Training

Training employees about safe computer use is critical to protecting data and mitigating the risks associated with cyberattacks. (Image by rawpixel © 123RF.com.)

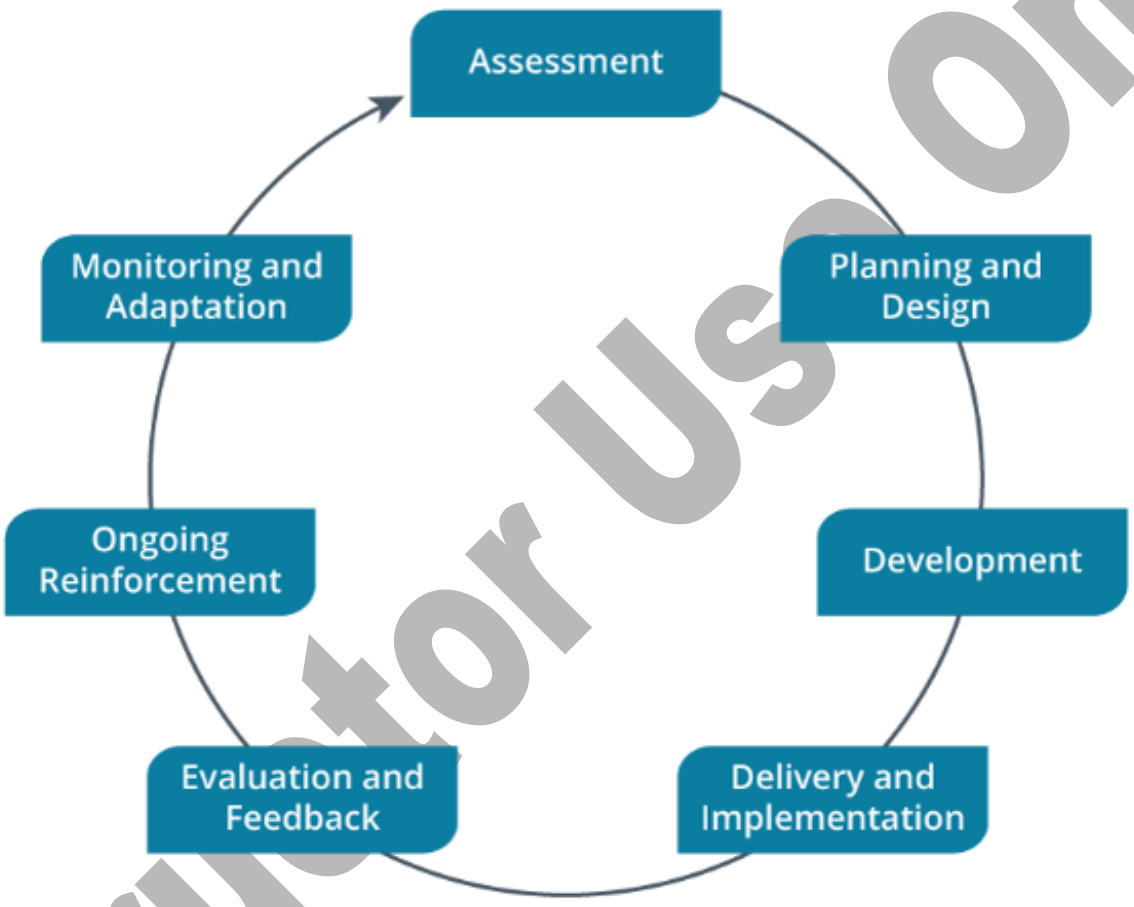
Phishing campaigns used as employee training mechanisms involve simulated attacks to raise awareness and educate employees about the risks and consequences of falling victim to such attacks. By conducting mock phishing exercises, organizations aim to enhance threat awareness, protect sensitive information, mitigate social engineering risks, promote incident response, and strengthen security practices. Phishing attacks are prevalent and pose significant risks to many industries, making it essential for employees to know how to defend against them. Phishing is an effective attack vector due to its exploitation of human vulnerabilities, deceptive impersonation of trusted entities, psychological manipulation, broad reach, ease of use, dynamic capabilities, adaptability, and the potential for significant financial gain. These factors make phishing attacks difficult to detect, mitigate and underscore the importance of practicing vigilance and regularly training employees to recognize and respond effectively to phishing attempts.

Through training, employees become more aware of common phishing techniques and deceptive tactics used by cybercriminals. This knowledge helps them to identify and report suspicious emails or messages, reducing the likelihood of data breaches and unauthorized access to sensitive information. By training employees to recognize phishing attempts, organizations mitigate social engineering risks. Employees learn to identify messages that use common tactics such as urgent requests, spoofed identities, and enticing offers to manipulate individuals. This knowledge helps protect employees and their organization from disclosing credentials or confidential data, or installing malware. Effective training enables employees to respond appropriately to phishing attempts, such as reporting incidents to specific IT or security teams, refraining from clicking suspicious links or opening attachments, and verifying requests sent via email using alternative channels. Training employees to recognize and respond to

phishing attempts strengthens an organization's cybersecurity defenses. It cultivates a culture of security awareness, empowers employees to protect sensitive information actively, and enhances the organization's resilience against evolving threats. Complemented by simulated phishing campaigns, regular training programs help build a knowledgeable and security-conscious workforce.

Security Awareness Training Lifecycle

Security awareness training practices typically follow a lifecycle approach consisting of several stages.



Security Awareness Training Lifecycle.

The first phase is assessing the organization's security needs and risks. Planning and designing awareness training activities follow, where a comprehensive plan is developed, including objectives, topics, and delivery methods. Once a plan is created, the development stage focuses on creating engaging and informative training materials. Training is then delivered through previously identified delivery methods, such as in-person or computer-based sessions. Evaluation and feedback activities assess the training's effectiveness and gather participant insights. Security awareness is reinforced via reoccurring training activities to ensure it remains a priority and often includes refresher training, reminders, newsletters, and awareness campaigns. Monitoring and adaptation allow organizations to continually evaluate the program's impact and make necessary adjustments based on emerging risks and changing requirements. Organizations can establish a continuous and effective security awareness training program by following this lifecycle. It helps enhance employee knowledge, steer behaviors, and cultivate a security culture within the organization. Regular assessment, evaluation, and adaptation ensure that training remains relevant and addresses evolving security threats. A well-structured security awareness training program significantly contributes to mitigating risks, protecting sensitive data, and building a resilient cybersecurity posture.

Development and Execution of Training

Successfully executing security training means effectively providing education and instruction to employees and staff that enhance their knowledge, skills, and awareness of security practices. It involves delivering training programs addressing relevant security topics, like data protection, incident response, phishing awareness, secure coding practices, physical security, and many others. Content development focuses on creating engaging and informative training materials, using clear language, and incorporating real-world examples to enhance relevance and mix interactive elements like quizzes, case studies, or simulations to encourage active participation, critical thinking, and practical application of knowledge. Facilitating dialogue, discussion, and question-and-answer sessions further enhance the learning experience. To assess the effectiveness of security awareness practices, collecting feedback, conducting assessments, and developing relevant measurements and metrics help gauge the impact of the training and identify areas for improvement. Regular reviews and updates to training materials ensure that its content remains relevant and aligned with evolving security threats. Incorporating emerging best practices and industry trends help organizations stay current and enhance their security awareness practices.

Reporting and Monitoring

One way to gauge the efficacy of security awareness training is to assess its influence initially and through ongoing evaluations.

Initial effectiveness refers to the immediate impact of security awareness training on participants. It measures the knowledge gained, awareness raised, and behavioral changes observed immediately after completing a training program. Evaluation methods can include pre-and post-training assessments, quizzes, and surveys designed to gauge participant understanding of security concepts before and after training. Measuring initial effectiveness provides insight into the immediate impact of training and how participants have absorbed the information and concepts presented.

Recurring effectiveness assesses the long-term impact and sustainability of security awareness training by examining whether participants have retained and applied the knowledge and skills gained from training in their day-to-day activities. The focus is to measure the continued behavioral changes and the level of security consciousness within the organization over an extended period.

Initial and recurring effectiveness measurements are crucial to gauge the overall impact of security awareness training. While measuring initial effectiveness shows the immediate outcomes and knowledge uptake, recurring effectiveness measurements ensure that the training has a lasting effect and leads to sustained improvements in security practices.

Assessments and Quizzes — Conducting pre- and post-training assessments and quizzes allow organizations to measure the knowledge gained by employees during training. These reports provide quantitative data regarding training effectiveness related to knowledge retention and comprehension.

Incident Reporting —Organizations can track and analyze incident reports to assess the training program's impact on incident detection and response, identifying any patterns or trends.

Phishing Simulations —Conducting simulated phishing campaigns helps organizations evaluate employees' ability to recognize and respond to phishing attempts. Reports generated from these simulations provide data on click rates, successful phish captures, and trends in susceptibility, indicating the effectiveness of the training in mitigating phishing risks.

Observations and Feedback —Managers and supervisors can provide feedback on employees' security practices and behaviors. Qualitative information such as this provides valuable insights into the practical application of training and any challenges employees face in implementing the knowledge gained.

Metrics and Performance Indicators —Tracking relevant metrics, such as the number of reported incidents, employee compliance with security policies, or changes in password hygiene, provides quantitative data on the impact of security awareness training. These metrics help measure the effectiveness of the training program over time.

Training Completion Rates —Monitoring the completion rates of security awareness training modules or sessions indicates employee engagement and adherence to training requirements. Higher completion rates suggest better participation and performance of the training content.

Anomalous Behavior

Anomalous behavior recognition refers to actions or patterns that deviate significantly from expectations. Examples include unusual network traffic, user account activity anomalies, insider threat actions, abnormal system events, and fraudulent transactions. Techniques such as network intrusion detection, user behavior analytics, system log analysis, and fraud detection are utilized to identify anomalous behavior. These techniques require monitoring and analyzing different data sources, comparing observed behavior against established baselines, and utilizing machine learning algorithms to detect deviations.

Recognizing Risky Behaviors

Risky behaviors are actions or practices that threaten data security, systems, or networks. These behaviors may involve unsafe online activities, such as clicking on suspicious links, visiting untrusted websites, or downloading unauthorized software. Risky behaviors can also include neglecting security measures, such as using weak passwords, sharing credentials, or ignoring software updates. Unexpected behaviors are actions that deviate from established security protocols or violate security policies. These behaviors can occur due to a lack of awareness, carelessness, or a failure to follow established procedures. Examples include unauthorized access to sensitive information, bypassing security controls, or disregarding physical security measures. Unintentional behaviors refer to actions without malicious intent but can still have detrimental consequences. These behaviors often stem from human error, lack of training, or lack of understanding of security best practices. Examples include accidental data breaches, mishandling of confidential information, or falling victim to social engineering attacks.

All three types of behaviors (risky, unexpected, and unintentional) can lead to security incidents, data breaches, or the compromise of sensitive information. Individuals must be aware of these behaviors, follow security guidelines, stay informed about emerging threats, and practice good cybersecurity hygiene. Organizations are responsible for training and educating employees about these behaviors to promote a security-conscious culture and minimize the impact of human-related vulnerabilities in the cybersecurity landscape.

13.2.3 Data Protection and Policies (Lesson Video)

Transcript:

In this lesson, I'm going to talk about data protection and policies. Data is a critical asset to all organizations, which must put specific policies in place for data creation, storage, and sharing.

One important data protection aspect is data retention. Data retention policies define how to organize, maintain, and archive data. They also outline how and when to dispose of information. Different data types must be legally retained for different lengths of time, depending on relevant regulations. Most data retention policies also address how to handle information involved in litigation. When you're creating a data retention policy, you need to identify the various data types your organization uses. Develop a policy that defines how long each data type should be retained as well as how they should be destroyed when the retention time expires. It's important to record this information in a policy that's clearly written. Having a written policy and ensuring that everyone in the organization follows it helps to protect you from evidence tampering accusations.
Adhering to your data retention policy protects both you and your organization. You should never allow selective or arbitrary information destruction, which could make it appear as though you're trying to hide evidence and could lead to criminal charges. Never destroy information after it's been subpoenaed or if you have reason to believe that it may be subpoenaed in the future. Evidence destruction and obstruction of justice are serious crimes that can result in imprisonment.
With this in mind, let's take a look at some examples of data retention rules. These rules aren't necessarily the ones that you'll use, but I'll go over them to give you ideas on how you can formulate your own policies.
Email inboxes can pile up quickly, so the first rule could state that all email messages are to be deleted after 90 days.
The IRS defines guidelines for maintaining tax records. To ensure compliance, you could say that your policy is to keep company tax records for seven years and employee tax records for four. After that time, they're to be shredded.

When it comes to employee HR records, a good rule of thumb is to keep them for three to four years.
You might see fit to hold onto all employee-created research and design documents to prove their ownership. So for the next rule, let's say the policy is to keep any integral research, design, or patent documents for 25 years.
Next, are vendor contracts, service-level agreements, and other types of contractual documents. A good practice is to keep these until five years after a contract has ended.
After you create your written data retention policy, consider using information classification labels to identify which retention policy rules apply to which pieces of data. This allows you to automate the data retention and destruction process. Without classification labels, it's an extremely tedious process to try to manage decades-long data records.
Having a solid data retention policy has a lot of benefits. First, it reduces the discovery-request cost in the event of legal action against your organization. Responding to discovery requests can be time consuming and costly. You significantly minimize your discovery costs if all your old, irrelevant material has already been destroyed. Second, it reduces exposure during the discovery process. By minimizing the amount of electronic material that your organization keeps on hand, you also reduce the amount of information that could potentially expose your organization to litigation. Third, it lowers the hardware and software requirements for storing old data and minimizes clutter.
That's it for this lesson. In this lesson, we talked about data protection and how to create data retention policies for your organization. We also talked about what specifically a data retention policy is and the good practices you should follow when creating one.

13.2.4 Data Protection and Policies Facts

Data protection and compliance encompass a range of practices and principles aimed at safeguarding sensitive information, ensuring privacy, and adhering to applicable laws and regulations. Data protection involves implementing measures to secure data against unauthorized access, loss, or misuse. It includes practices such as encryption, access controls, data backup, and secure storage. Compliance refers to conforming to legal, regulatory, and industry requirements relevant to data handling, privacy, security, and transparency. Organizations can safeguard individuals' privacy, ensure data security, fulfill legal requirements, and establish credibility with customers, partners, and regulatory authorities by comprehending and implementing these data protection and compliance principles. Compliance with applicable data protection laws, regulations, and standards is crucial for organizations to avoid legal liabilities, reputational damage, and financial penalties associated with noncompliance.

This lesson covers the following topics:

- Data protection
- Data loss prevention
- Data sovereignty and geographical considerations
- Data retention policies

Data Protection

Classifying data as "at rest," "in motion," and "in use" is crucial for effective data protection and security measures. By analyzing data based on its state (at rest, in motion, in use), organizations can tailor security measures and controls to address the specific risks and requirements associated with each data state. This classification helps organizations identify vulnerabilities, prioritize security investments, and ensure appropriate safeguards to protect sensitive data throughout its lifecycle. It also facilitates compliance with data protection regulations and industry best practices.

- **Data at rest** — this state means that the data is in some sort of persistent storage media. Examples of types of data that may be at rest include financial information stored in databases, archived audiovisual media, operational policies and other management documents, system configuration data, and more. In this state, it is usually possible to encrypt the data using techniques such as whole disk encryption, database encryption , and file- or folder-level encryption. It is also possible to apply permissions—access control lists (ACLs)—to ensure only authorized users can read or modify the data. ACLs can be applied only if access to the data is fully mediated through a trusted OS.

Data in transit (or data in motion) — this is the state when data is transmitted over a network. Examples of types of data that may be in transit include website traffic, remote access traffic, data being synchronized between cloud repositories, and more. In this state, data can be protected by a transport encryption protocol, such as TLS or IPSec.

With data at rest, there is a greater encryption challenge than with data in transit, as the encryption keys must be kept secure for longer. Transport encryption can use ephemeral (session) keys.

Data in use (or data in processing) — this is the state when data is present in volatile memory, such as system RAM or CPU registers and cache. Examples of types of data that may be in use include documents open in a word processing application, database data that is currently being modified, event logs being generated while an operating system is running, and more. When a user works with data, it usually needs to be decrypted as it goes from in rest to in use. The data may stay decrypted for an entire work session, which puts it at risk. However, trusted execution environment (TEE) mechanisms, such as Intel Software Guard Extensions (software.intel.com/content/www/us/en/develop/topics/software-guard-extensions/details.html), can encrypt data as it exists in memory so that an untrusted process cannot decode the information.

Due diligence in the context of data protection describes the comprehensive assessment and evaluation of an organization's data protection practices and measures. It involves examining and verifying the adequacy of data security controls, privacy policies, data handling procedures, and compliance with applicable laws and regulations.

Data Loss Prevention

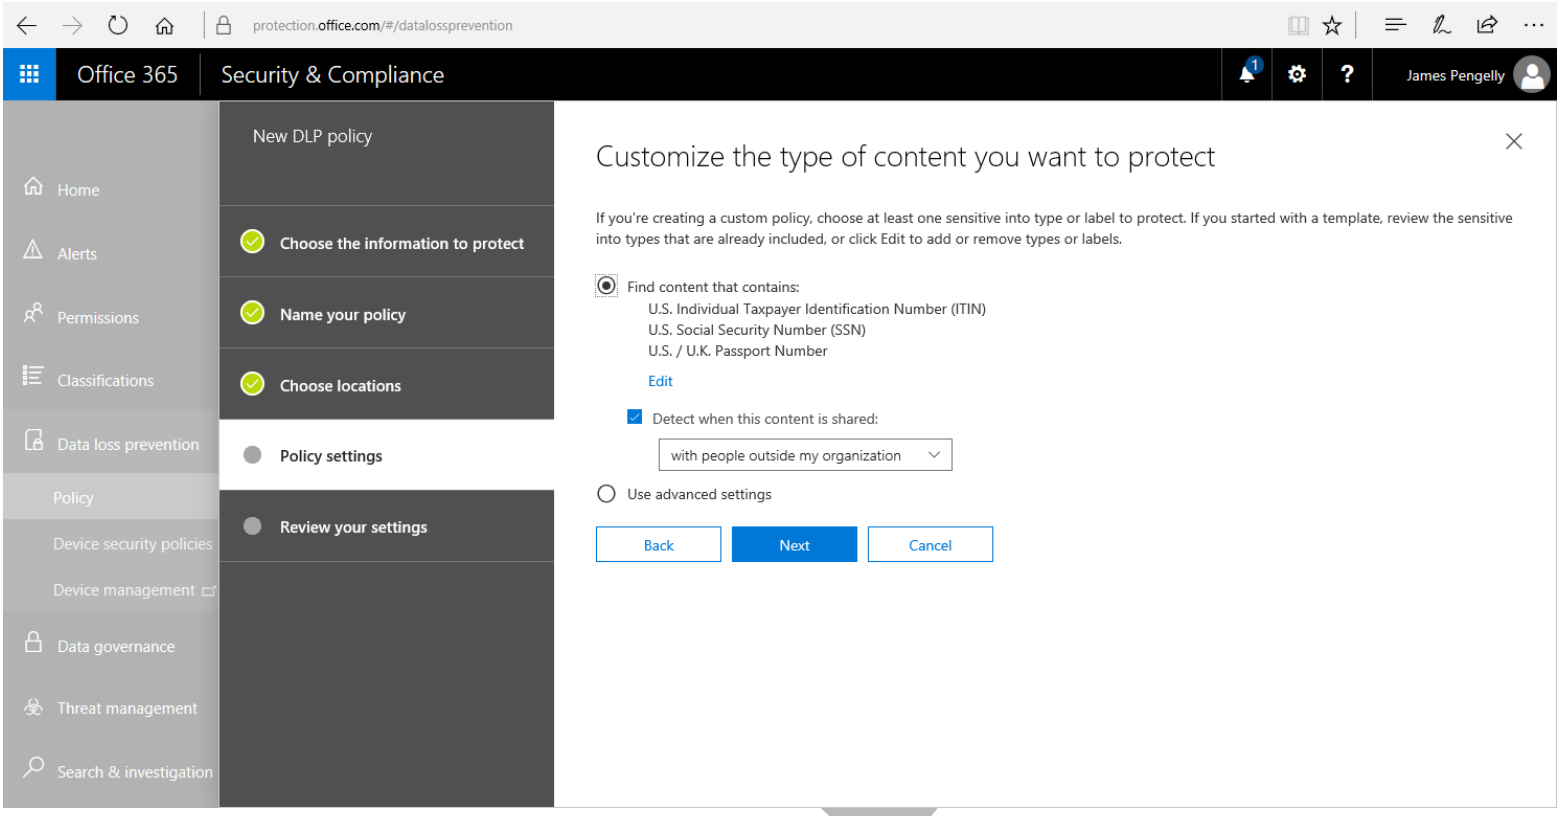
To apply data guardianship policies and procedures, smaller organizations might classify and type data manually. However, an organization that creates and collects large amounts of personal data will usually need to use automated tools to assist with this task. There may also be a requirement to protect valuable intellectual property (IP) data. Data loss prevention (DLP) products automate the discovery and classification of data types and enforce rules so that data is not viewed or transferred without proper authorization. Such solutions will usually consist of the following components:

Policy server — to configure classification, confidentiality, and privacy rules and policies, log incidents, and compile reports.

Endpoint agents — to enforce policy on client computers, even when they are not connected to the network.

Network agents — to scan communications at network borders and interface with web and messaging servers to enforce policy.

DLP agents scan content in structured formats, such as a database with a formal access control model, or unstructured formats, such as email or word processing documents. A file cracking process is applied to unstructured data to render it in a consistent scannable format. The transfer of content to removable media, such as USB devices, by email, instant messaging, or even social media, can be blocked if it does not conform to a predefined policy. Most DLP solutions can extend the protection mechanisms to cloud storage services, using either a proxy to mediate access or the cloud service provider's API to perform scanning and policy enforcement.



Creating a DLP policy in Office 365. (Screenshot used with permission from Microsoft.)

Remediation is the action the DLP software takes when it detects a policy violation. The following remediation mechanisms are typical:

Alert only — copying is allowed, but the management system records an incident and may alert an administrator.

Block — the user is prevented from copying the original file but retains access. The user may or may not be alerted to the policy violation, but it will be logged as an incident by the management engine.

Quarantine — access to the original file is denied to the user (or possibly any user). This might be accomplished by encrypting the file in place or by moving it to a quarantine area in the file system.

Tombstone — the original file is quarantined and replaced with one describing the policy violation and how the user can release it again.

When configured to protect a communications channel such as email, DLP remediation might take place using client-side or server-side mechanisms. For example, some DLP solutions prevent the actual attaching of files to the email before it is sent. Others might scan the email attachments and message contents and then strip out certain data or stop the email from reaching its destination.

Data Sovereignty and Geographical Considerations

Some states and nations may respect data privacy more or less than others, and likewise, some nations may disapprove of the nature and content of certain data. They may even be suspicious of security measures such as encryption. When your data is stored or transmitted in other jurisdictions or when you collect data from citizens in other states or other countries, you may not "own" the data in the same way as you'd expect or like to.

Data Sovereignty

Data sovereignty refers to a jurisdiction preventing or restricting processing and storage from taking place on systems that do not physically reside within that jurisdiction. Data sovereignty may demand certain concessions on your part, such as using location-specific storage facilities in a cloud service.

For example, GDPR protections are extended to any EU citizen while they are within EU or EEA (European Economic Area) borders. Data subjects can consent to allow a transfer, but there must be a meaningful option for them to refuse consent. If the transfer destination jurisdiction does not provide adequate privacy regulations (to a level comparable to GDPR), then contractual safeguards must be given to extend GDPR rights to the data subject. In the United States, companies can self-certify that the protections they offer are adequate under the Privacy Shield scheme (privacyshield.gov/US-Businesses).

Maintaining compliance with data sovereignty requirements requires several approaches. Organizations ensure data localization by storing and processing data using datacenters or cloud providers within defined legal or geographic boundaries. Additionally, contractual agreements with vendors and service providers ensure data remains within approved boundaries by outlining responsibilities, restrictions, and mandatory safeguards.

Geographical Considerations

Geographic access requirements fall into two different scenarios:

- Storage locations might have to be carefully selected to mitigate data sovereignty issues. Most cloud providers allow a choice of datacenters for processing and storage, ensuring that information is not illegally transferred from a particular privacy jurisdiction without consent.

- Employees needing access from multiple geographic locations. Cloud-based file and database services can apply constraint-based access controls to validate the user's geographic location before authorizing access.

Geographic restrictions impact other business functions:

- Geolocation requirements impact data protection practices by requiring organizations to ensure data remains within a designated boundary, such as utilizing local datacenters or cloud providers. Geolocation restrictions affect data protection practices such as data replication and data dispersion.

- Geolocation requirements impact incident investigation and forensics activities because they often include jurisdiction-specific data access and sharing restrictions and other legal requirements.

Data Retention Policies

Data retention policies define how information in your possession is maintained and for how long. The key point to remember is that different types of data must be retained for different lengths of time based on legal and business requirements.

Data retention policies also typically describe procedures for:

- Archiving information

- Destroying information when the retention limit is reached

- Handling information involved in litigation

Review all the different types of information used in your organization and develop a policy that defines how long different types of data are retained and destroyed when the retention period is passed. Record this information in a clearly written policy, and never

allow selective or arbitrary information destruction. It might make it appear that you are trying to hide evidence and could expose you to potential criminal charges.

Benefits of Data Retention Policies

Having a written policy and ensuring everyone in the organization follows it protects you from accusations of destroying evidence. Adhering to your data retention and destruction policy protects you and your organization.

Other benefits of implementing a data retention policy include:

- Reduced cost of discovery requests in the event of legal action. Responding to discovery requests can be time-consuming and costly. If old material has been destroyed, discovery costs are minimized.
- Reduced exposure during discovery. Minimizing the amount of electronic material an organization keeps reduces the amount of information that could expose an organization to potential litigation.
- Reduced hardware and software requirements for storing old data.

Data Retention Best Practices

Some best practices include:

- Delete email messages after 90 days.
- Keep tax-related information for seven years. This timeframe should be defined by the applicable taxation authority. For example, the United States Internal Revenue Service requires tax information to be retained for seven years.
- Keep employee records for four years after an employee leaves the organization.
- Keep integral research, design, or patent documents for 25 years.
- Keep contracts with vendors and partners for five years after a contract has ended.
- Delete employee files after one year.
- All information should be destroyed before being disposed of. Simply deleting files can leave sensitive information behind.
- After creating your written data retention policy, use information classification labels to identify which retention policy rule is to be applied to specific data. Using classification labels allows you to use software tools to automate the data retention and destruction process.

13.2.5 Practice Questions (Section Quiz)

q_pers_pol_aup_01_secp8

A medium-sized organization is undergoing an audit for its information security practices. As a security analyst, the auditor seeks to assess the organization's use of an acceptable use policy (AUP).

What crucial aspect of the AUP should the auditor focus on to ensure the organization meets the standards set for information security?

Answers:

***The AUP includes clear consequences for noncompliance.**

The AUP includes guidance for personal use of organizational resources.

The AUP includes the number of allowed password attempts before locking an account.

The AUP includes a list of approved software for each department.

Explanation:

Any acceptable use policy crucially outlines clear consequences for noncompliance, which serves to deter potential violators and provides a clear path for action when violations occur.

While an AUP might offer guidance for personal use of organizational resources, its primary focus remains on regulating the use of these resources to maintain security.

A password policy or an account lockout policy, not an AUP, typically includes the provision for the number of allowed password attempts before locking an account.

The policy known as the approved software list, not the AUP, includes the list of approved software for each department.

q_pers_pol_aup_02_secp8

An organization recently experienced a security breach due to the actions of an employee who engaged in an activity that posed a risk to the company's information systems. The employee downloaded unverified software onto the company device, resulting in a malware infection.

Following this incident, the company plans to implement a policy to prevent similar occurrences in the future.

Which of the following policies is MOST suitable for addressing this specific issue?

Answers:

Business continuity and continuity of operations plans (COOP)

***Acceptable use policy (AUP)**

Disaster recovery policy

Change management policy

Explanation:

AUP sets the standard for acceptable behavior by users on network and computer systems. The AUP typically comprises rules about software downloads, aiming to deter users from participating in activities that could damage the organization or its resources.

COOP policies strive to keep critical processes running during and following significant disruption. However, these policies do not directly tackle the problem of an employee downloading risky software.

A disaster recovery policy concentrates on the resumption of operations after a catastrophic event but does not incorporate preventive measures against risky behaviors by users, such as unauthorized software downloads.

A change management policy describes the process for requesting, reviewing, approving, and implementing changes to IT systems and software.

q_pers_pol_aup_03_secp8

A new employee reviews key guidance given by the department manager. The manager reminds the new employee to pay close attention to the directive that concerns all electronic usage.

What documents should the employee review? (Select two.)

Answers:

***AUP**

***Information security policy**

Change management

SDLC

Clean desk policy

Explanation:

An acceptable use policy (AUP) outlines how individuals may use network and computer systems by defining what constitutes acceptable behavior by users. AUPs typically address browsing behavior, appropriate content, software downloads, and handling sensitive information.

Information security policies are policies an organization creates to ensure that all information technology users comply with rules and guidelines related to the security of the information stored within the environment or the organization's sphere of authority.

Change management policies govern the requests, reviews, approvals, and implementation of IT systems and software changes.

Software Development Lifecycle (SDLC) policies govern software development within an organization. They do not govern what employees can do with electronics.

A clean desk policy means that each employee's work area should be free from any documents left there. The aim of the policy is to prevent sensitive information from being obtained by unauthorized staff or guests at the workplace. It does not focus on electronic usage.

q_pers_pol_clean_desk_01_secp8

An organization observes employees leaving sensitive documents on their desks, thereby exposing sensitive data in the work area. To stop unauthorized staff or guests from accessing this information, the organization decides to introduce a new policy.

Which policy would resolve this issue?

Answers:

Acceptable use policy

***Clean desk policy**

Code of conduct and social media analysis

Use of personally owned devices in the workplace

Explanation:

A clean desk policy ensures that each employee's work area is free from any documents left there, preventing unauthorized staff or guests from obtaining sensitive information.

Acceptable use policy mainly concerns using the organization's equipment and technology, forbidding actions such as defrauding, defaming, obtaining illegal material, and unauthorized access to confidential data.

Code of conduct and social media analysis do not directly address the issue of sensitive documents left unattended on desks.

This policy concerns the threats portable devices pose to data security, including file copying and recording functions and the unauthorized use of personal software. It does not address the issue of sensitive documents left out in the open.

q_pers_pol_clean_desk_02_secp8

A company had data for an upcoming project stolen and leaked online. The investigation implies that social engineering is the cause.

Which policy can prevent such an incident from occurring?

Answers:

***Clean desk**

Fair use

Standard operating procedure (SOP)

Non-disclosure agreement (NDA)

Explanation:

A clean desk policy means an employee's work area should be free from documents or information. The policy aims to prevent sensitive information from prying eyes.

A fair use (or acceptable use) policy defines what someone can do while using a particular service or resource (such as using systems at a business).

A standard operating procedure (SOP) is a documented list of steps or actions to perform a task to a specified and expected standard.

A non-disclosure agreement (NDA) is a document between parties (such as an employer and employee) for a legal basis in protecting information assets. In this situation the information was stolen, not disclosed by an employee, and social engineering was involved.

q_pers_pol_clean_desk_03_secp8

A user invited a friend to the office for a tour. There were several moments when no one was around the visitor. During these times, the friend might have viewed confidential information.

What type of policy can prevent such an activity from occurring?

Answers:

***Clean desk**

Fair use

Standard operating procedure (SOP)

Non-disclosure agreement (NDA)

Explanation:

A clean desk policy means an employee's work area should be free from any documents or information. The policy aims to prevent sensitive information from prying eyes.

A fair use (or acceptable use) policy defines what someone can do while using a particular service or resource (such as using systems at a business).

A standard operating procedure (SOP) is a documented list of steps or actions to perform a task to a specified and expected standard.

A non-disclosure agreement (NDA) is put into place between parties (such as an employer and employee) as a legal basis for protecting information assets.

q_pers_pol_incident_response_secp8

Which policy outlines the processes to follow after a security breach or cyberattack occurs and includes procedures for identifying, investigating, controlling, and mitigating the impact of incidents?

Answers:

***Incident response policy**

Acceptable use policy (AUP)

Disaster recovery policy

Change management policy

Explanation:

The incident response policy is vital in managing cybersecurity incidents effectively. It outlines the steps to follow after a security breach or cyberattack, providing guidelines for identifying, investigating, controlling, and mitigating the impact of such incidents.

The acceptable use policy (AUP) outlines acceptable uses for network and computer systems, defining appropriate user behavior and addressing consequences for noncompliance.

The disaster recovery policy details steps required to recover from catastrophic events like natural disasters or significant security breaches, aiming to restore operations quickly and efficiently.

A change management policy governs the request, review, approval, and implementation of IT systems and software changes, including documentation requirements.

q_pers_pol_offboarding_secp8

An organization has hired an HR director to improve the performance of the HR division. The director first noted the lack of an offboarding process for employees or contractors.

What are some IT security areas an offboarding process should focus on? (Select three.)

Answers:

***Account management**

***Physical security**

Personal assets

***Company assets**

Clean desk

Acceptable use

Asset allocation

Explanation:

The following are focus areas during the offboarding process:

When a user leaves, the HR division immediately deactivates the account, marking it for auto-deletion later.

While not always related to IT security, physical security and the items that support physical security are important to keep track of.

An organization must account for any electronic devices employees use during employment, returning them before their departure. An inventory sheet allows for the accounting of all of the property previously in their control.

The following are not the direct focus of an offboarding process:

Any personal devices (assets) used for company activities must have the proprietary information removed, including the removal of any software purchased by the company.

A clean desk means that each employee's work area should be free from any documents left there, which is not a primary focus of offboarding.

An acceptable use policy (AUP) is important to protect the organization from the security and legal implications of employees misusing its equipment. However, it is not a primary focus of offboarding.

Asset allocation provisions computers or mobile devices for the user, including the use of bring-your-own-device handsets. This is an onboarding issue, not an offboarding issue.

q_pers_pol_phishing_sims_secp8

As the head of the IT department in your organization, you have noticed an increase in the number of phishing attempts targeting your employees. You have implemented several measures to combat this, but the attempts continue to rise.

Which of the following strategies would be the most effective in addressing this issue?

Answers:

Implement a stricter internet usage policy and block access to all non-work-related websites.

***Conduct regular phishing simulations to test employee awareness and response.**

Increase the frequency of system-wide password changes.

Install more advanced antivirus software on all company computers.

Explanation:

Conducting regular phishing simulations is the most effective strategy. This approach not only tests the current level of employee awareness but also provides a practical, hands-on learning experience for employees. It allows you to identify who is most at risk and tailor your training accordingly. This method directly addresses the issue and helps to improve the overall security posture of the organization.

Implementing a stricter internet usage policy and blocking access to all non-work-related websites may reduce the risk of phishing attempts, but it could also hinder employee productivity and morale. It does not directly address the issue of phishing and does not provide employees with the knowledge or skills to identify and avoid phishing attempts.

Increasing the frequency of system-wide password changes can improve security, but it does not directly address phishing attempts. Furthermore, it could lead to employee frustration and potentially weaker passwords if employees struggle to remember their constantly changing login credentials.

Installing more advanced antivirus software can help to detect and block phishing attempts, but it is not a foolproof solution. Some phishing attempts may still get through, and without proper awareness and training, employees may still fall for these attempts.

q_pers_pol_risky_behaviors_secp8

As a cybersecurity analyst, you are tasked with identifying risky behaviors among employees that could potentially lead to security breaches.

Which of the following behaviors would you consider to be the MOST risky and why?

Answers:

An employee frequently works late and accesses the company network after hours.

An employee uses their personal smartphone to check work emails.

***An employee regularly uses the same password for multiple systems and applications.**

An employee occasionally forgets to log out of their workstation when they leave for lunch.

Explanation:

Using the same password for multiple systems and applications is the most risky behavior. If one system or application is compromised, all others that use the same password are also at risk. This behavior makes it easy for attackers to gain access to multiple areas of the network, potentially leading to a significant security breach.

While an employee accessing the company network after hours could potentially pose a risk, it is not inherently risky behavior. Many employees work late or outside of normal business hours. The key is to ensure that the network is secure at all times, regardless of when it is being accessed.

Using a personal smartphone to check work emails can pose a risk if the phone is lost or stolen, or if it is infected with malware. However, with proper security measures in place, such as encryption and remote wipe capabilities, this risk can be mitigated.

Forgetting to log out of a workstation can pose a risk, particularly if the workstation is left unattended in a public or shared space. However, this risk can be mitigated with automatic log-out settings and screen locks. While it is a risky behavior, it is not as risky as using the same password for multiple systems and applications.

q_pers_pol_training_01_secp8

A software development company recognizes that some of its employees are vulnerable to phishing attacks. To address this, the company plans to set up a training program.

What factors should the company primarily consider while defining such training programs?

Answers:

The job titles of the employees

The personal interests of the employees

***The roles performed by the employees**

The length of service of the employees

Explanation:

Employees may perform different roles and have different security training, education, or awareness requirements in each role. Therefore, focusing on job roles rather than job titles is essential in setting up effective security training programs.

Job titles might not accurately reflect an employee's roles, responsibilities, and security training needs.

While it may be useful to consider personal interests to enhance engagement, this should not be the primary factor in defining security training programs.

While the length of service might influence an employee's experience or familiarity with security issues, it is not a primary factor in determining the training needs for specific roles.

q_pers_pol_training_02_secp8

A software application contains sensitive transmittal information, and an end user takes it out on a laptop in the field. The end user must understand how to protect and dispose of the data.

Which one of the following should help the end user prepare for this?

Answers:

***User training**

Vendor-specific guide

General purpose guide

Change management

Explanation:

User training teaches users new functionality and proper policies and procedures for both the company and the software. Users should complete training before using the system to prevent incidents and to understand what to do in the event of one.

Vendor-specific guides provide instructions on installing and securely configuring hardware and software for a specific vendor.

General purpose guides help increase security in hardware and software by providing instructions for configuring a system based on roles and appliances.

Change management is a process that involves the prevention of unauthorized changes to a system. This process protects from unwanted outages.

q_pers_pol_training_lifecycle_secp8

As the security awareness training manager at your company, you have recently completed a round of training sessions on the company's security policies.

However, a few weeks later, you notice that some employees are not adhering to the policies, particularly those related to secure email practices.

What should you do?

Answers:

Ignore the issue, assuming that employees will eventually learn from their mistakes.

Immediately fire the employees who are not following the secure email practices.

***Implement ongoing reinforcement strategies, such as regular reminders, mini-training sessions, and visual aids around the office, to keep the secure email practices fresh in employees' minds.**

Discipline the employees by restricting their access to certain company resources.

Explanation:

Ongoing reinforcement is a key part of the security awareness training lifecycle and the correct answer. Regular reminders, mini-training sessions, and visual aids can help keep the secure email practices fresh in employees' minds, leading to better adherence to the policies.

Ignoring the issue does not solve the problem and could potentially lead to more severe security breaches. As the security awareness training manager, it is your responsibility to address any security issues that arise.

Firing employees is not a constructive solution to the problem. It does not address the root cause of the issue, which is the lack of understanding or adherence to password management guidelines.

Disciplining employees by restricting their access to company resources does not solve the problem. It could also lead to a decrease in productivity and employee morale. The goal of the Security Awareness Training program is to educate employees, not to punish them.

q_pers_pol_update_training_secp8

A company has recently experienced a significant increase in phishing attacks. The IT department has implemented technical controls to block phishing emails, but some are still getting through.

The company has a security awareness training program, but it has not been updated in several years.

What should be the company's immediate action to address this issue?

Answers:

***Update the security awareness training program to include information about the latest phishing techniques and conduct a company-wide training session.**

Invest in more advanced technical controls to block phishing emails.

Conduct a company-wide training session using the existing security awareness training program.

Discipline employees who fall for phishing attacks to deter others from making the same mistake.

Explanation:

Updating the security awareness training program to include information about the latest phishing techniques and conducting a company-wide training session is the correct answer and would help employees recognize and avoid phishing emails. This is a proactive approach that addresses the root cause of the problem.

While investing in more advanced technical controls might help block more phishing emails, it doesn't address the issue of employees not being able to recognize and avoid phishing emails that do get through.

Conducting a company-wide training session using the existing security awareness training program would not be as effective because the program has not been updated in several years and likely does not include information about the latest phishing techniques.

Disciplining employees who fall for phishing attacks might create a culture of fear and discourage employees from reporting when they do fall for phishing attacks. This could potentially make the problem worse. It's more effective to educate employees so they can recognize and avoid phishing attacks.

q_dataprot_pol_adhere_secp8

As the data protection officer at a large corporation, you have just completed the development of a comprehensive data retention policy. The policy includes specific retention periods for different types of data, procedures for archiving and destroying information, and guidelines for handling information involved in litigation.

A few weeks after the policy has been implemented, you discover that a department within the corporation has been selectively deleting certain types of data before the retention limit is reached. The department head argues that the data is not relevant to their operations and is taking up unnecessary storage space.

How should you respond?

Answers:

Allow the department to continue deleting the data, but ask them to document their actions for transparency.

***Insist that the department adhere to the data retention policy, explaining the potential legal and business implications of not doing so.**

Modify the data retention policy to allow for selective deletion of data if it is deemed irrelevant to a department's operations.

Report the department's actions to senior management and recommend disciplinary action.

Explanation:

Insisting that the department adhere to the data retention policy is the correct answer. As the data protection officer, it is your responsibility to ensure that the data retention policy is adhered to across the corporation. The policy was put in place to protect the corporation and its data, and any deviations from it could have serious implications.

Allowing the department to continue deleting the data is not the best because it undermines the integrity of the data retention policy. While transparency is important, allowing selective deletion of data could expose the corporation to potential legal risks and accusations of evidence destruction.

Modifying the data retention policy to allow for selective deletion of data is not advisable because it could lead to inconsistencies in how data is handled across the corporation. It could also potentially expose the corporation to legal risks if data is deleted prematurely.

While it's important to report non-compliance, recommending disciplinary action immediately may not be the best first step. It's better to first ensure the department understands the importance of the data retention policy and the potential implications of not adhering to it.

q_dataprot_pol_data_at_rest_secp8

A system administrator implemented encryption across the organization's IT infrastructure. The infrastructure includes various types of data storage methods.

Which of the following data storage methods can the system administrator encrypt to increase the security of data at rest? (Select three.)

Answers:

***Volume**

***File**

***Partition**

User interface

Website traffic

Remote access

Cloud repository synchronization

Explanation:

A volume is a single accessible storage area spanning a single partition on a hard drive or encompassing an entire storage device. When encrypted, an attacker cannot decipher the information without the encryption key.

File-level encryption allows for the encryption of individual files as opposed to an entire disk or volume.

Similar to volume encryption, partition encryption converts the entirety of the data within the specified partition into an unreadable format without the correct encryption key.

The following are data storage methods that are not designed to increase the security of data at rest:

The user interface (UI) is how users interact with a system or software. Since the UI is not a data storage method, it does not contain data at rest and, therefore, does not require encryption.

Website traffic, remote access, and cloud repository synchronization are all associated with data in transit.

q_dataprot_pol_data_in_use_secp8

A recent security flaw allowed a malicious actor to access sensitive data even though the data never left the server and there is full drive encryption.

Which data state did the malicious actor MOST likely compromise?

Answers:

In transit

At rest

***In use**

Through bluetooth

Explanation:

Data in use (or data in processing) refers to the state in which data is present in volatile memory, such as system Random Access Memory (RAM) or Central Processing Unit (CPU) registers and cache. The security flaw allows for data exploitation while in use.

Data in transit (or data in motion) is the state in which data transmits over a network. In the scenario, the data never left the server.

Data at rest refers to the state when the data is in some persistent storage media. In the scenario, there is hard drive encryption.

Bluetooth would involve data in transit and not relate to the exposure of data in use.

q_dataprot_pol_dlp_secp8

After a recent breach, an organization mandates increased monitoring of corporate email accounts.

What can the organization use that mediates the copying of tagged data to restrict it to authorized media and services and monitors statistics for policy violations?

Answers:

***Data loss prevention**

Antivirus (A-V)

Security content automation protocol

Simple Network Management Protocol (SNMP) trap

Explanation:

Data loss prevention (DLP) mediates the copying of tagged data to restrict it to authorized media and services and monitors statistics for policy violations.

Antivirus (A-V) software detects and removes infections and (in most cases) other types of malware, such as worms, Trojans, rootkits, adware, spyware, password crackers, network mappers, and denial-of-service (DoS) tools.

Security content automation protocol (SCAP) allows compatible scanners to determine whether a computer meets a configuration baseline.

A Simple Network Management Protocol (SNMP) trap informs the management system of a notable event such as port failure, chassis overheating, power failure, or excessive Central Processing Unit (CPU) utilization.

q_dataprot_pol_due_diligence_01_secp8

A healthcare provider is preparing for an upcoming audit of its patient data management system. The chief compliance officer focuses on ensuring that the organization has taken the necessary steps to identify and minimize risks related to the handling of patient data.

What is the chief compliance officer primarily concentrating on?

Answers:

***Due diligence and care**

Attestation and acknowledgment

Data encryption strategy

Employee training program

Explanation:

Due diligence and care refer to the organization's responsibility to identify and minimize risks. In an upcoming audit for patient data management, the chief compliance officer focuses on taking necessary steps to identify and minimize risks.

Attestation and acknowledgment involve formally asserting that the organization has met certain conditions or requirements, typically through signed documents.

A data encryption strategy is a critical part of data protection. However, it is not the focus of identifying and minimizing risks, which is the primary task of the chief compliance officer.

Training is essential but is not the focal point of the chief compliance officer's current task of identifying and minimizing risks through careful examination and action.

q_dataprot_pol_due_diligence_02_secp8

A new tech firm creates measures to ensure it adheres to all compliance and data privacy aspects.

What describes the comprehensive assessment and evaluation of an organization's data protection practices and measures?

Answers:

***Due diligence**

Attestation and acknowledgment

Data inventories

Data retention

Explanation:

Due diligence in data protection describes the comprehensive assessment and evaluation of an organization's data protection practices and measures.

Attestation and acknowledgment require individuals or entities to formally acknowledge their understanding of compliance obligations and commitment to adhere to them through signed agreements, policy acknowledgments, and training activities.

Data inventories provide a comprehensive overview of the types of handled data, the purposes for processing, the legal basis, and the recipients of the data to ensure transparency and accountability.

Data retention is another area impacted by privacy laws. Organizations must retain personal data only for as long as necessary to fulfill the intended purpose or as required by law.

q_dataprot_pol_due_diligence_03_secp8

A software technician develops a new procedure to safeguard privacy data and ensure all groups adhere to compliance mandates.

What BEST describes due diligence?

Answers:

***It is the comprehensive assessment and evaluation of an organization's data protection practices.**

It requires individuals or entities to formally announce their understanding of compliance obligations.

It provides a comprehensive overview of the types of handled data.

It is an established timeline that requires organizations to keep documentation.

Explanation:

Due diligence in data protection describes the comprehensive assessment and evaluation of an organization's data protection practices and measures.

Attestation and acknowledgment require individuals or entities to formally acknowledge their understanding of compliance obligations and commitment to adhere to them through signed agreements, policy acknowledgments, and training activities.

Data inventories provide a comprehensive overview of the types of handled data, the purposes for processing, the legal basis, and the recipients of the data to ensure transparency and accountability.

Data retention is another area impacted by privacy laws. Organizations must retain personal data only for as long as necessary to fulfill the intended purpose or as required by law.

q_dataprot_pol_encryption_01_secp8

A financial organization has hired a cybersecurity expert to strengthen the security of its system.

The expert recommends implementing a specific technique into unreadable ciphertext by converting plaintext credit card information, regardless if it is active, in transit, or at rest.

What technique should the cybersecurity expert implement?

Answers:

***Encryption**

Tokenization

Obfuscation

Hashing

Explanation:

Encryption is a process that transforms plaintext information into an unreadable format using an encryption algorithm and a key. This process is suitable for protecting sensitive data in all states: at rest, in transit, or in use.

Tokenization provides a level of data protection, but it does not transform the original data into an unreadable format.

Obfuscation is a method of making something difficult to understand or find, such as a message or data, but it does not necessarily convert data into an unreadable format.

Hashing converts data into a fixed-size string of characters, representing the data's digital fingerprint. However, hashing is a one-way function. Upon hashing data, it is irreversible, and the original data is irretrievable.

q_dataprot_pol_encryption_02_secp8

A sole proprietorship construction company contacted an information technology (IT) consultant for technical support for a computer issue. After resolving that issue, the consultant suggested the construction company enable computer encryption.

Why might the company want to enable encryption on its computers' hard drives?

Answers:

To slow down data removal from a stolen device.

To prevent phishing

***To prevent data removal from a stolen device**

To prevent theft

Explanation:

Enabling hard drive encryption is a basic step to prevent data loss in the event of a stolen device. Without it, anyone can easily access the stolen device, regardless of needing a password.

The purpose of hard drive encryption is to prevent data loss in the event of a stolen device. However, as technology improves, malicious actors can exploit weaknesses in encryption.

Hard drive encryption does not prevent phishing. However, malicious actors could use information from an unencrypted hard drive to phish other people.

Hard drive encryption may dissuade theft, but it will not prevent theft. A malicious actor can still wipe a hard drive to reuse it.

q_dataprot_pol_encryption_03_secp8

A chief executive officer pushed back against the information technology department's proposal to set up disk encryption on all devices.

What BEST describes why the CEO should approve the proposal instead of pushing back against it?

Answers:

***Disk encryption protects the company from data theft in case of stolen devices.**

Disk encryption slows down a computer's performance.

The costs are not worth incurring.

The company does not have enough sensitive data.

Explanation:

Disk encryption protects against data theft when a malicious actor steals a device. The data remains safe as long as the malicious actor does not have the keys.

Disk encryption will slow performance and can be a negative impact. However, most modern disk encryption suites only lock down access to the data when the device is off.

Disk encryption can save a company significant costs associated with loss. The cost of setting up disk encryption is significantly less than the financial impacts on a company.

Even a limited amount of sensitive data is worth protecting with encryption to save financial and legal costs associated with loss or theft of the data.

q_dataprot_pol_geolocation_secp8

A cloud storage company wants to ensure that it stores user data in the same country as the user's physical location.

Which factor is the cloud storage company primarily considering here?

Answers:

***Geolocation**

Data sovereignty

Data classification

Data integrity

Explanation:

Geolocation refers to the identification of the geographic location of an object, such as a computing device or server.

Data sovereignty is relevant in this context. However, in this scenario, the primary factor the cloud storage company is considering is where it should store user data based on the user's location, which is a task for geolocation.

Data classification involves categorizing data based on its sensitivity level (i.e., public, confidential). This process can help organizations determine appropriate security measures, but it is not the primary factor the cloud storage company is considering.

Data integrity is maintaining and assuring the accuracy and consistency of data over its lifecycle. While a critical aspect of data management, it is not the primary consideration.

q_dataprot_pol_keep_emails_secp8

You are the IT manager at a mid-sized company. The company has a data retention policy in place that requires all emails to be deleted after 90 days.

However, the sales Ddpartment has been keeping all their emails for potential customer follow-ups and references. They argue that these emails are crucial for their operations and customer relations.

How should you handle this situation?

Answers:

Allow the sales department to keep their emails indefinitely as they are crucial for their operations.

Insist that the sales department adheres to the company's data retention policy and deletes all emails after 90 days.

***Work with the sales department to identify a solution that allows them to keep important customer-related emails while still adhering to the data retention policy.**

Report the sales department's non-compliance to the company's senior management and let them handle the situation.

Explanation:

Working with the sales department to identify a solution is the correct answer. It's important to maintain the integrity of the data retention policy while also considering the unique needs of different departments. Working with the sales department to identify a solution that allows them to keep important customer-related emails could be a win-win situation.

Allowing the sales department to keep their emails indefinitely is not advisable because it undermines the company's data retention policy. Allowing one department to keep their emails indefinitely could lead to inconsistencies and potential legal risks.

Insisting that the sales department adheres to the company's data retention policy, while adhering strictly to the policy, does not take into consideration the unique needs of the sales department. It could potentially harm the company's customer relations and sales operations.

While it's important to report non-compliance, it's also crucial to work towards a solution first. Reporting the situation to senior management without trying to resolve it first could lead to unnecessary conflicts and misunderstandings.

q_dataprot_pol_permission_01_secp8

A systems administrator receives an alert for potential unauthorized access to sensitive data while in active memory on a server within the organization. The organization has tasked the systems administrator with enforcing stricter controls to prevent such breaches.

What would be the MOST appropriate measure to implement?

Answers:

***Permission restrictions**

Data encryption

Data masking

Data obfuscation

Explanation:

Permission restrictions are an ideal option to secure data in use. Implementing permission restrictions would limit access to only authorized users, reducing the likelihood of unauthorized access.

Data encryption is an effective way to protect data at rest or in transit, but it does not typically secure data while the system processes it or when it is in active memory.

Data masking creates a structurally similar but inauthentic version of an organization's data and is not the most appropriate method for securing data in use.

Data obfuscation makes data harder to understand, making it difficult for an unauthorized user to make sense of the data. However, it is less appropriate for data in active memory compared to permission restrictions.

q_dataprot_pol_permission_02_secp8

A network engineer in an organization receives a notification regarding a potential data breach involving confidential information currently in active memory on one of their servers. The organization has decided to enforce stricter measures to prevent unauthorized access to such data.

What would be the MOST effective solution for this issue?

Answers:

***Permission restrictions**

Data encryption

Data masking

Data obfuscation

Explanation:

Permission restrictions are an ideal option to secure data in use. Implementing permission restrictions would limit access to only authorized users, reducing the likelihood of unauthorized access.

Data encryption is an effective way to protect data at rest or in transit, but it does not typically secure data while the system processes it or when it is in active memory.

Data masking creates a structurally similar but inauthentic version of an organization's data and is not the most appropriate method for securing data in use.

Data obfuscation makes data harder to understand, making it difficult for an unauthorized user to make sense of the data. However, it is less appropriate for data in active memory compared to permission restrictions.

q_dataprot_pol_privacy_secp8

A company is updating its standard operating procedures (SOPs).

What type of policy should a company focus on to ensure compliance with data privacy regulations and outline the appropriate handling of customer data?

Answers:

***Data privacy policy**

Acceptable use policy (AUP)

Information security policy

Disaster recovery policy

Explanation:

The data privacy policy defines how the company collects, stores, processes, and shares customer data and measures taken to protect customer information. It ensures that the organization complies with relevant data protection laws and regulations, safeguarding sensitive data and promoting transparency in data handling practices.

An acceptable use policy outlines appropriate computer and network usage but doesn't cover data privacy regulations or customer information management.

An information security policy is essential to ensure that all users follow the guidelines related to information security. However, it may not cover data privacy regulations and customer data management.

A disaster recovery policy primarily deals with the steps to recover from catastrophic events such as natural disasters or security breaches.

q_dataprot_pol_retention_secp8

In a high-security environment, which of the following is the MOST important concern when removable media is no longer needed?

Answers:

Labeling

***Destruction**

Reuse

Purging

Explanation:

The most important concern is the destruction of the media. In a high-security environment, removable media is not reused. After the media is no longer needed, it must be destroyed.

Labeling is important, but it is important before removable media is put into use, not after.

Reuse and purging are not secure activities in a high-security environment. Reusing media can result in confidentiality compromise. Purging is rarely sufficient to fully remove data.

q_dataprot_pol_sovereignty_01_secp8

Which of the following is a correct interpretation of data sovereignty?

Answers:

***A jurisdiction can restrict or prevent processing and storage of data on systems that do not physically reside within that jurisdiction.**

The physical location of a data center has no bearing on the jurisdiction and laws applicable to the data stored within it.

Data can freely move across borders with no restrictions or regulations.

All data is inherently owned by the organization or individual who created it, regardless of where it is stored or processed.

Explanation:

Data sovereignty is the principle that a jurisdiction can impose restrictions or prevent the processing and storage of data on systems that do not physically reside within that jurisdiction. It often requires organizations to use location-specific storage facilities or cloud services.

The physical location of a data center often directly determines the jurisdiction and laws applicable to the data stored within it.

Data sovereignty is the opposite of this, often placing restrictions and regulations on how and where the user can move and store data.

While data ownership is a complex issue and can depend on various factors, data sovereignty refers to the laws and regulations on how and where the user can move and store data.

q_dataprot_pol_sovereignty_02_secp8

Planning to store data from various global branches, an international company is assessing the legal and regulatory compliance requirements for data storage and usage.

What should the organization consider in its analysis of government requirements?

Answers:

***Data sovereignty**

Data transfer rules

Local privacy laws

Geographic restrictions

Explanation:

Data sovereignty is the concept that data is subject to the laws and governance structures within the nation the company collects data. Complying with data sovereignty laws is crucial for an international company storing data from different locations.

Data transfer rules refer to the regulations governing the movement of data. The primary concern for an international company would be the specific laws in each country where it stores data.

Local privacy laws are a part of the considerations under data sovereignty. However, data sovereignty encompasses more than just local privacy laws.

Geographic restrictions refer to data management limitations based on geographic location. The term does not encapsulate the full range of legal and regulatory considerations.

A.0 CompTIA Security+ SY0-701 - Practice Exams

A.1 Prepare for CompTIA Security+ SY0-701 Certification

It is important to prepare for an exam by studying course material, practicing skills, and committing new concepts to memory. You can use the instructions and tests in this course to help you prepare more efficiently.

We recommend that you take the following steps as you prepare for the CompTIA Security+ SY0-701 exam:

Step	Description
Step 1: Study the course material	**Study the course materials for each section** . The course materials include text lessons, demonstrations, video lessons, and hands-on labs. As you work through the course, follow these hints for the most effective study: Review the learning and exam objectives on each section page. The objectives outline the knowledge and skills you will need for the official certification exam. Watch the videos. Watch the demonstrations. Read all text lesson fact pages. Practice the tasks in the lab simulations until you feel comfortable with your ability to complete them. Even if you already know the material, a review will be helpful when preparing for an exam.
Step 2: Take the section practice quizzes	**Pass all the Section Quizzes and be able to explain why the answers are correct.** The Section Quizzes at the end of each section will help you assess your understanding of the content for that section. Use the immediate feedback to go back and study the course material covering the questions you missed. After you have mastered the material in a section, move on to the next section.
Step 3: Study the domain review questions	**Study the Domain Review questions for each domain.** When you have finished studying the course material and passed all the Section Quizzes, you are ready to focus on exam preparation and review questions by certification exam domain. There are two types available:

	20 Questions - Twenty questions are randomly selected from the available pool of questions for a specific exam domain. All Questions - All questions from the available pool of questions for a specific exam domain are presented. This option allows the review of all available questions by exam domain.
Step 4: Take the certification practice exam	**Pass the certification practice exam with at least a 95% passing score.** After you are confident with your ability to answer each question, take the certification practice exam to assess your preparedness to take the certification exam. This exam has roughly the same number of questions and time limit as the certification exam. Check your answers after each exam, then review the course material for questions that you missed. Practice questions are designed to assess your knowledge as it relates to the exam objectives. Focus your time on understanding the topics covered in the objectives and not on memorizing answers, as the actual certification exam will have a different set of questions. It is recommended that you pass the certification practice exam multiple times as you will receive random questions each time. When you feel confident in your understanding of the exam objectives and topics, the next step is to take the certification exam.
Step 5: Schedule and take the certification exam	When you have completed the previous steps and feel prepared, schedule the CompTIA Security+ SY0-701 exam through Pearson VUE. Details on how to schedule an exam are provided in this section.

A.1.1 Security+ SY0-701 Exam Objectives

The Security Pro course and certification exam cover the following CompTIA Security+ SY0-701 objectives:

#	Domain	Module.Section
1.0	**General Security Concepts**	
1.1	Compare and contrast various types of security controls 1.1.1 - Categories 1.1.1.1 - Technical	1.1, 1.2 5.10 7.1

	1.1.1.2 - Managerial 1.1.1.3 - Operational 1.1.1.4 - Physical 1.1.2 - Control types 1.1.2.1 - Preventive 1.1.2.2 - Deterrent 1.1.2.3 - Detective 1.1.2.4 - Corrective 1.1.2.5 - Compensating 1.1.2.6 - Directive	
1.2	Summarize fundamental security concepts 1.2.1 - Confidentiality, Integrity, and Availability (CIA) 1.2.2 - Non-repudiation 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.1 - Authenticating people 1.2.3.2 - Authenticating systems 1.2.3.3 - Authorization models 1.2.4 - Gap analysis 1.2.5 - Zero trust 1.2.5.1 - Control plane 1.2.5.1.1 - Adaptive identity 1.2.5.1.2 - Threat scope reduction 1.2.5.1.3 - Policy-driven access control 1.2.5.1.4 - Policy Administrator 1.2.5.1.5 - Policy Engine	1.1 4.1, 4.2, 4.3, 4.4, 4.5 5.2 6.1 8.2 10.4

	1.2.5.2 - Data plane 1.2.5.2.1 - Implicit trust zones 1.2.5.2.2 - Subject/System 1.2.5.2.3 - Policy enforcement point 1.2.6 - Physical security 1.2.6.1 - Bollards 1.2.6.2 - Access control vestibule 1.2.6.3 - Fencing 1.2.6.4 - Video surveillance 1.2.6.5 - Security guard 1.2.6.6 - Access badge 1.2.6.7 - Lighting 1.2.6.8 - Sensors 1.2.6.8.1 - Infrared 1.2.6.8.2 - Pressure 1.2.6.8.3 - Microwave 1.2.6.8.4 - Ultrasonic 1.2.7 - Deception and disruption technology 1.2.7.1 - Honeypot 1.2.7.2 - Honeynet 1.2.7.3 - Honeyfile 1.2.7.4 - Honeytoken	
1.3	Explain the importance of change management processes and the impact to security 1.3.1 - Business processes impacting security operation 1.3.1.1 - Approval process	8.9 11.2

	1.3.1.2 - Ownership 1.3.1.3 - Stakeholders 1.3.1.4 - Impact analysis 1.3.1.5 - Test results 1.3.1.6 - Backout plan 1.3.1.7 - Maintenance window 1.3.1.8 - Standard operating procedure 1.3.2 - Technical implications 1.3.2.1 - Allow lists/deny lists 1.3.2.2 - Restricted activities 1.3.2.3 - Downtime 1.3.2.4 - Service restart 1.3.2.5 - Application restart 1.3.2.6 - Legacy applications 1.3.2.7 - Dependencies 1.3.3 - Documentation 1.3.3.1 - Updating diagrams 1.3.3.2 - Updating policies/procedures 1.3.4 -Version control	
1.4	Explain the importance of using appropriate cryptographic solutions 1.4.1 - Public key infrastructure (PKI) 1.4.1.1 - Public key 1.4.1.2 - Private key 1.4.1.3 - Key escrow 1.4.2 - Encryption	3.1, 3.2, 3.3, 3.4, 3.5 4.3 5.8 6.6 7.3 8.1, 8.2, 8.7 10.8

- 1.4.2.1 - Level
  - 1.4.2.1.1 - Full-disk
  - 1.4.2.1.2 - Partition
  - 1.4.2.1.3 - File
  - 1.4.2.1.4 - Volume
  - 1.4.2.1.5 - Database
  - 1.4.2.1.6 - Record
- 1.4.2.2 - Transport/communication
- 1.4.2.3 - Asymmetric
- 1.4.2.4 - Symmetric
- 1.4.2.5 - Key exchange
- 1.4.2.6 - Algorithms
- 1.4.2.7 - Key length

1.4.3 - Tools

- 1.4.3.1 - Trusted Platform Module (TPM)
- 1.4.3.2 - Hardware security module (HSM)
- 1.4.3.3 - Key management system
- 1.4.3.4 - Secure enclave

1.4.4 - Obfuscation

- 1.4.4.1 - Steganography
- 1.4.4.2 - Tokenization
- 1.4.4.3 - Data masking

1.4.5 - Hashing

1.4.6 - Salting

1.4.7 - Digital signatures

	1.4.8 - Key stretching 1.4.9 - Blockchain 1.4.10 - Open public ledger 1.4.11 - Certificates 1.4.11.1 - Certificate authorities 1.4.11.2 - Certificate revocation lists (CRLs) 1.4.11.3 - Online Certificate Status Protocol (OCSP) 1.4.11.4 - Self-signed 1.4.11.5 - Third-party 1.4.11.6 - Root of trust 1.4.11.7 - Certificate signing request (CSR) generation 1.4.11.8 - Wildcard	
2.0	**Threats, Vulnerabilities, and Mitigations**	
2.1	Compare and contrast common threat actors and motivations 2.1.1 - Threat actors 2.1.1.1 - Nation-state 2.1.1.2 - Unskilled attacker 2.1.1.3 - Hacktivist 2.1.1.4 - Insider threat 2.1.1.5 - Organized crime 2.1.1.6 - Shadow IT 2.1.2 - Attributes of actors 2.1.2.1 - Internal/external 2.1.2.2 - Resources/funding	1.1 2.1, 2.2 6.5

	2.1.2.3 - Level of sophistication/capability 2.1.3 - Motivations 2.1.3.1 - Data exfiltration 2.1.3.2 - Espionage 2.1.3.3 - Service disruption 2.1.3.4 - Blackmail 2.1.3.5 - Financial gain 2.1.3.6 - Philosophical/political beliefs 2.1.3.7- Ethical 2.1.3.8 - Revenge 2.1.3.9 - Disruption/chaos 2.1.3.10 - War	
2.2	Explain common threat vectors and attack surfaces 2.2.1 - Message-based 2.2.1.1 - Email 2.2.1.2 - Short Message Service (SMS) 2.2.1.3 - Instant messaging (IM) 2.2.2 - Image-based 2.2.3 - File-based 2.2.4 - Voice call 2.2.5 - Removable device 2.2.6 - Vulnerable software 2.2.6.1 - Client-based vs. agentless 2.2.7 - Unsupported systems and applications 2.2.8 - Unsecure networks	2.1, 2.2 5.10 6.2, 6.6 7.2, 7.4 8.1, 8.2, 8.3, 8.5, 8.6, 8.9 10.4, 10.7, 10.8

	2.2.8.1 - Wireless 2.2.8.2 - Wired 2.2.8.3 - Bluetooth 2.2.9 - Open service ports 2.2.10 - Default credentials 2.2.11 - Supply chain 2.2.11.1 - Managed service providers (MSPs) 2.2.11.2 - Vendors 2.2.11.3 - Suppliers 2.2.12 - Human vectors/social engineering 2.2.12.1 - Phishing 2.2.12.2 - Vishing 2.2.12.3 - Smishing 2.2.12.4 - Misinformation/disinformation 2.2.12.5 - Impersonation 2.2.12.6 - Business email compromise 2.2.12.7 - Pretexting 2.2.12.8 - Watering hole 2.2.12.9 - Brand impersonation 2.2.12.10 - Typosquatting	
2.3	Explain various types of vulnerabilities 2.3.1 - Application 2.3.1.1 - Memory injection 2.3.1.2 - Buffer overflow 2.3.1.3 - Race conditions	2.1 5.7, 5.10 7.1 8.6, 8.8 10.1, 10.4, 10.5

- 2.3.1.3.1 - Time-of-check (TOC)
- 2.3.1.3.2 - Time-of-use (TOU)
- 2.3.1.4 - Malicious update

2.3.2 - Operating system (OS)-based

2.3.3 - Web-based

- 2.3.3.1 - Structured Query Language injection (SQLi)
- 2.3.3.2 - Cross-site scripting (XSS)

2.3.4 - Hardware

- 2.3.4.1 - Firmware
- 2.3.4.2 - End-of-life
- 2.3.4.3 - Legacy

2.3.5 - Virtualization

- 2.3.5.1 - Virtual machine (VM) escape
- 2.3.5.2 - Resource reuse

2.3.6 - Cloud-specific

2.3.7 - Supply chain

- 2.3.7.1 - Service provider
- 2.3.7.2 - Hardware provider
- 2.3.7.3 - Software provider

2.3.8 - Cryptographic

2.3.9 - Misconfiguration

2.3.10 - Mobile device

- 2.3.10.1 - Side loading
- 2.3.10.2 - Jailbreaking

2.3.11 - Zero-day

2.4	Given a scenario, analyze indicators of malicious activity 2.4.1 - Malware attacks 2.4.1.1 - Ransomware 2.4.1.2 - Trojan 2.4.1.3 - Worm 2.4.1.4 - Spyware 2.4.1.5 - Bloatware 2.4.1.6 - Virus 2.4.1.7 - Keylogger 2.4.1.8 - Logic bomb 2.4.1.9 - Rootkit 2.4.2 - Physical attacks 2.4.2.1 - Brute force 2.4.2.2 - Radio frequency identification (RFID) cloning 2.4.2.3 - Environmental 2.4.3 - Network attacks 2.4.3.1 - Distributed denial-of-service (DDoS) 2.4.3.1.1 - Amplified 2.4.3.1.2 - Reflected 2.4.3.2 - Domain Name System (DNS) attacks 2.4.3.3 - Wireless 2.4.3.4 - On-path 2.4.3.5 - Credential replay 2.4.3.6 - Malicious code	2.1, 2.3 3.1 4.5 5.7 6.1, 6.4, 6.5, 6.6 8.5, 8.7, 8.8 10.9

	2.4.4 - Application attacks 2.4.4.1 - Injection 2.4.4.2 - Buffer overflow 2.4.4.3 - Replay 2.4.4.4 - Privilege escalation 2.4.4.5 - Forgery 2.4.4.6 - Directory traversal 2.4.5 - Cryptographic attacks 2.4.5.1 - Downgrade 2.4.5.2 - Collision 2.4.5.3 - Birthday 2.4.6 - Password attacks 2.4.6.1 - Spraying 2.4.6.2 - Brute force 2.4.7 - Indicators 2.4.7.1 - Account lockout 2.4.7.2 - Concurrent session usage 2.4.7.3 - Blocked content 2.4.7.4 - Impossible travel 2.4.7.5 - Resource consumption 2.4.7.6 - Resource inaccessibility 2.4.7.7 - Out-of-cycle logging 2.4.7.8 - Published/documented 2.4.7.9 - Missing logs	
2.5	Explain the purpose of mitigation techniques used to secure the enterprise	2.1 3.4 4.1, 4.3, 4.6

	2.5.1 - Segmentation 2.5.2 - Access control 2.5.2.1 - Access control list (ACL) 2.5.2.2 - Permissions 2.5.3 - Application allow list 2.5.4 - Isolation 2.5.5 - Patching 2.5.6 - Encryption 2.5.7 - Monitoring 2.5.8 - Least privilege 2.5.9 - Configuration enforcement 2.5.10 - Decommissioning 2.5.11 - Hardening techniques 2.5.11.1 - Encryption 2.5.11.2 - Installation of endpoint protection 2.5.11.3 - Host-based firewall 2.5.11.4 - Host-based intrusion prevention system (HIPS) 2.5.11.5 - Disabling ports/protocols 2.5.11.6 - Default password changes 2.5.11.7 - Removal of unnecessary software	5.4, 5.7, 5.10 6.2, 6.3, 6.4 7.3 8.1, 8.2, 8.3, 8.6, 8.8, 8.9 9.1, 9.2 10.1, 10.5, 10.6, 10.7 13.2
3.0	**Security Architecture**	
3.1	Compare and contrast security implications of different architecture models 3.1.1 - Architecture and infrastructure concepts 3.1.1.1 - Cloud	5.1 9.4 10.1, 10.2, 10.3, 10.4, 10.6, 10.8

- 3.1.1.1.1 - Responsibility matrix
- 3.1.1.1.2 - Hybrid considerations
- 3.1.1.1.3 - Third-party vendors
- 3.1.1.2 - Infrastructure as code (IaC)
- 3.1.1.3 - Serverless
- 3.1.1.4 - Microservices
- 3.1.1.5 - Network infrastructure
- 3.1.1.5.1 - Physical isolation
- 3.1.1.5.1.1 - Air-gapped

- 3.1.1.8 - Containerization
- 3.1.1.9 - Virtualization
- 3.1.1.10 - IoT
- 3.1.1.11 - Industrial control systems (ICS)/supervisory control and data acquisition (SCADA)
- 3.1.1.12 - Real-time operating system (RTOS)
- 3.1.1.13 - Embedded systems
- 3.1.1.14 - High availability

3.1.2 - Considerations

- 3.1.2.1 - Availability
- 3.1.2.2 - Resilience
- 3.1.2.3 - Cost

	3.1.2.4 - Responsiveness 3.1.2.5 - Scalability 3.1.2.6 - Ease of deployment 3.1.2.7 - Risk transference 3.1.2.8 - Ease of recovery 3.1.2.9 - Patch availability 3.1.2.10 - Inability to patch 3.1.2.11 - Power 3.1.2.12 - Compute	
3.2	Given a scenario, apply security principles to secure enterprise infrastructure 3.2.1 - Infrastructure considerations 3.2.1.1 - Device placement 3.2.1.2 - Security zones 3.2.1.3 - Attack surface 3.2.1.4 - Connectivity 3.2.1.5 - Failure modes 3.2.1.5.1 - Fail-open 3.2.1.5.2 - Fail-closed 3.2.1.6 - Device attribute 3.2.1.6.1 - Active vs. passive 3.2.1.6.2 - Inline vs. tap/monitor 3.2.1.7 - Network appliances 3.2.1.7.1 - Jump server 3.2.1.7.2 - Proxy server 3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS)	2.1 4.8 5.1, 5.2, 5.3, 5.4, 5.5, 5.9, 5.10 6.3 7.3 8.2, 8.6, 8.7, 8.8 9.2, 9.4 10.1, 10.2, 10.9

	3.2.1.7.4 - Load balancer 3.2.1.7.5 - Sensors 3.2.1.8 - Port security 3.2.1.8.1 - 802.1X 3.2.1.8.2 - Extensible Authentication Protocol (EAP) 3.2.1.9 - Firewall types 3.2.1.9.1 - Web application firewall (WAF) 3.2.1.9.2 - Unified threat management (UTM) 3.2.1.9.3 - Next-generation firewall (NGFW) 3.2.1.9.4 - Layer 4/Layer 7 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 3.2.2.2 - Remote access 3.2.2.3 - Tunneling 3.2.2.3.1 - Transport Layer Security (TLS) 3.2.2.3.2 - Internet protocol security (IPSec) 3.2.2.4 - Software-defined wide area network (SD-WAN) 3.2.2.5 - Secure access service edge (SASE) 3.2.3 - Selection of effective controls	
3.3	Compare and contrast concepts and strategies to protect data 3.3.1 - Data types 3.3.1.1 - Regulated 3.3.1.2 - Trade secret 3.3.1.3 - Intellectual property	5.9, 5.10 7.3 8.9 10.5, 10.8 13.1, 13.2

- 3.3.1.4 - Legal information
- 3.3.1.5 - Financial information
- 3.3.1.6 - Human and non-human readable

3.3.2 - Data classifications

- 3.3.2.1 - Sensitive
- 3.3.2.2 - Confidential
- 3.3.2.3 - Public
- 3.3.2.4 - Restricted
- 3.3.2.5 - Private
- 3.3.2.6 - Critical

3.3.3 - General data considerations

- 3.3.3.1 - Data states
  - 3.3.3.1.1 - Data at rest
  - 3.3.3.1.2 - Data in transit
  - 3.3.3.1.3 - Data in use
- 3.3.3.2 - Data sovereignty
- 3.3.3.3 - Geolocation

3.3.4 - Methods to secure data

- 3.3.4.1 - Geographic restrictions
- 3.3.4.2 - Encryption
- 3.3.4.3 - Hashing
- 3.3.4.4 - Masking
- 3.3.4.5 - Tokenization
- 3.3.4.6 - Obfuscation
- 3.3.4.7 - Segmentation

	3.3.4.8 - Permission restrictions	
3.4	Explain the importance of resilience and recovery in security architecture 3.4.1 - High availability 3.4.1.1 - Load balancing vs. clustering 3.4.2 - Site considerations 3.4.2.1 - Hot 3.4.2.2 - Cold 3.4.2.3 - Warm 3.4.2.4 - Geographic dispersion 3.4.3 - Platform diversity 3.4.4 - Multi-cloud systems 3.4.5 - Continuity of operations 3.4.6 - Capacity planning 3.4.6.1 - People 3.4.6.2 - Technology 3.4.6.3 - Infrastructure 3.4.7 - Testing 3.4.7.1 - Tabletop exercises 3.4.7.2 - Fail over 3.4.7.3 - Simulation 3.4.7.4 - Parallel processing 3.4.8 - Backups 3.4.8.1 - Onsite/offsite 3.4.8.2 - Frequency 3.4.8.3 - Encryption	6.1 9.4, 9.5 10.1, 10.4 12.1

	3.4.8.4 - Snapshots 3.4.8.5 - Recovery 3.4.8.6 - Replication 3.4.8.7 - Journaling 3.4.9 - Power 3.4.9.1 - Generators 3.4.9.2 - Uninterruptible power supply (UPS)	
4.0	**Security Operations**	
4.1	Given a scenario, apply common security techniques to computing resources 4.1.1 - Secure baselines 4.1.1.1 - Establish 4.1.1.2 - Deploy 4.1.1.3 - Maintain 4.1.2 - Hardening targets 4.1.2.1 - Mobile devices 4.1.2.2 - Workstations 4.1.2.3 - Switches 4.1.2.4 - Routers 4.1.2.5 - Cloud infrastructure 4.1.2.6 - Servers 4.1.2.7 - ICS/SCADA 4.1.2.8 - Embedded systems 4.1.2.9 - RTOS 4.1.2.10 - IoT devices 4.1.3. Wireless devices	3.5 4.6, 4.8 5.9, 5.10 6.2, 6.4 7.3 8.1, 8.2, 8.4, 8.5, 8.6, 8.8, 8.9 9.2 10.1, 10.2, 10.4, 10.5, 10.6, 10.7, 10.8, 10.9 13.2

4.1.3.1 - Installation considerations

4.1.3.1.1 - Site surveys

4.1.3.1.2 - Heat maps

4.1.4 - Mobile solutions

4.1.4.1 - Mobile device management (MDM)

4.1.4.2 - Deployment models

4.1.4.2.1 - Bring your own device (BYOD)

4.1.4.2.2 - Corporate-owned, personally enabled (COPE)

4.1.4.2.3 - Choose your own device (CYOD)

4.1.4.3 - Connections methods

4.1.4.3.1 - Cellular

4.1.4.3.2 - Wi-Fi

4.1.4.3.3 - Bluetooth

4.1.5 - Wireless security settings

4.1.5.1 - Wi-Fi Protected Access 3 (WPA3)

4.1.5.2 - AAA/Remote Authentication Dial-In User Service (RADIUS)

4.1.5.3 - Cryptographic protocols

4.1.5.4 - Authentication protocols

4.1.6 - Application security

4.1.6.1 - Input validation

4.1.6.2 - Secure cookies

4.1.6.3 - Static code analysis

4.1.6.4 - Code signing

4.1.7. Sandboxing

4.1.8. Monitoring

4.2	Explain the security implications of proper hardware, software, and data asset management 4.2.1 - Acquisition/procurement process 4.2.2 - Assignment/accounting 4.2.2.1 - Ownership 4.2.2.2 - Classification 4.2.3 - Disposal/decommissioning 4.2.3.1 - Sanitization 4.2.3.2 - Destruction 4.2.3.3 - Certification 4.2.3.4 - Data retention	8.2 10.6 12.1 13.1, 13.2
4.3	Explain various activities associated with vulnerability management 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan 4.3.1.2 - Application security 4.3.1.2.1 - Static analysis 4.3.1.2.2 - Dynamic analysis 4.3.1.2.3 - Package monitoring 4.3.1.3 - Threat feed 4.3.1.3.1 - Open-source intelligence (OSINT) 4.3.1.3.2 - Proprietary/third-party 4.3.1.3.3 - Information-sharing organization 4.3.1.3.4 - Dark web 4.3.1.4 - Penetration testing 4.3.1.5 - Responsible disclosure program 4.3.1.5.1 - Bug bounty program	5.8 6.2, 6.3 7.1, 7.2, 7.3, 7.4 8.1, 8.2, 8.9 9.2 10.1 12.3

	4.3.1.6 - System/process audit 4.3.2 - Analysis 4.3.2.1 - Confirmation 4.3.2.1.1 - False positive 4.3.2.1.2 - False negative 4.3.2.2 - Prioritize 4.3.2.3 - Common Vulnerability Scoring System (CVSS) 4.3.2.4 - Common Vulnerability Enumeration (CVE) 4.3.2.5 - Vulnerability classification 4.3.2.6 - Exposure factor 4.3.2.7 - Environmental variables 4.3.2.8 - Industry/organizational impact 4.3.2.9 - Risk tolerance 4.3.3 - Vulnerability response and remediation 4.3.3.1 - Patching 4.3.3.2 - Insurance 4.3.3.3 - Segmentation 4.3.3.4 - Compensating controls 4.3.3.5 - Exceptions and exemptions 4.3.4 - Validation of remediation 4.3.4.1 - Rescanning 4.3.4.2 - Audit 4.3.4.3 - Verification 4.3.5 - Reporting	
4.4	Explain security alerting and monitoring concepts and tools	6.2

	4.4.1 - Monitoring computing resources 4.4.1.1 - Systems 4.4.1.2 - Applications 4.4.1.3 - Infrastructure 4.4.2 - Activities 4.4.2.1 - Log aggregation 4.4.2.2 - Alerting 4.4.2.3 - Scanning 4.4.2.4 - Reporting 4.4.2.5 - Archiving 4.4.2.6 - Alert response and remediation/validation 4.4.2.6.1 - Quarantine 4.4.2.6.2 - Alert tuning 4.4.3 - Tools 4.4.3.1 - Security Content Automation Protocol (SCAP) 4.4.3.2 - Benchmarks 4.4.3.3 - Agents/agentless 4.4.3.3.1 - Security information and event management (SIEM) 4.4.3.3.2 - Antivirus 4.4.3.3.3 - Data loss prevention (DLP) 4.4.3.4 - Simple Network Management Protocol (SNMP) traps 4.4.3.5 - NetFlow 4.4.3.6 - Vulnerability scanners	7.1, 7.2, 7.3, 7.4 9.2 12.3 13.2

4.5	Given a scenario, modify enterprise capabilities to enhance security 4.5.1 - Firewall 4.5.1.1 - Rules 4.5.1.2 - Access lists 4.5.1.3 - Ports/protocols 4.5.1.4 - Screened subnets 4.5.2 - IDS/IPS 4.5.2.1 - Trends 4.5.2.2 - Signatures 4.5.3 - Web filter 4.5.3.1 - Agent-based 4.5.3.2 - Centralized proxy 4.5.3.3 - Universal Resource Locator (URL) scanning 4.5.3.4 - Content categorization 4.5.3.5 - Block rules 4.5.3.6 - Reputation 4.5.4 - Operating system security 4.5.4.1 - Group Policy 4.5.4.2 - SELinux 4.5.5 - Implementation of secure protocols 4.5.5.1 - Protocol selection 4.5.5.2 - Port selection 4.5.5.3 - Transport method 4.5.6 - DNS filtering	4.4, 4.5, 4.6 5.2, 5.3, 5.4, 5.6, 5.9, 5.10 6.2, 6.3, 6.4 8.1, 8.2, 8.9 10.5, 10.7, 10.9 12.3

	4.5.7 - Email security 4.5.7.1 - Domain-based Message Authentication Reporting and Conformance (DMARC) 4.5.7.2 - DomainKeys Identified Mail (DKIM) 4.5.7.3 - Sender Policy Framework (SPF) 4.5.7.4 - Gateway 4.5.8. File integrity monitoring 4.5.9. DLP 4.5.10. Network access control (NAC) 4.5.11. Endpoint detection and response (EDR)/extended detection and response (XDR) 4.5.12. User behavior analytics	
4.6	Given a scenario, implement and maintain identity and access management 4.6.1 - Provisioning/de-provisioning user accounts 4.6.2 - Permission assignments and implications 4.6.3 - Identity proofing 4.6.4 - Federation 4.6.5 - Single sign-on (SSO) 4.6.5.1 - Lightweight Directory Access Protocol (LDAP) 4.6.5.2 - Open authorization (OAuth) 4.6.5.3 - Security Assertions Markup Language (SAML) 4.6.6 - Interoperability 4.6.7 - Attestation 4.6.8 - Access controls 4.6.8.1 - Mandatory	4.1, 4.2, 4.3, 4.5, 4.6, 4.7, 4.9 5.7 6.1 8.1, 8.2, 8.8, 8.9 10.5, 10.7 11.1 13.2

4.6.8.2 - Discretionary

4.6.8.3 - Role-based

4.6.8.4 - Rule-based

4.6.8.5 - Attribute-based

4.6.8.6 - Time-of-day restrictions

4.6.8.7 - Least privilege

4.6.9 - Multifactor authentication

4.6.9.1 - Implementations

4.6.9.1.1 - Biometrics

4.6.9.1.2 - Hard/soft authentication tokens

4.6.9.1.3 - Security keys

4.6.9.2 - Factors

4.6.9.2.1 - Something you know

4.6.9.2.2 - Something you have

4.6.9.2.3 - Something you are

4.6.9.2.4 - Somewhere you are

4.6.10 - Password concepts

4.6.10.1 - Password best practices

4.6.10.1.1 - Length

4.6.10.1.2 - Complexity

4.6.10.1.3 - Reuse

4.6.10.1.4 - Expiration

4.6.10.1.5 - Age

4.6.10.2 - Password managers

4.6.10.3 - Passwordless

	4.6.11 - Privileged access management tools 4.6.11.1 - Just-in-time permissions 4.6.11.2 - Password vaulting 4.6.11.3 - Temporal accounts	
4.7	Explain the importance of automation and orchestration related to secure operations 4.7.1 - Use cases of automation and scripting 4.7.1.1 - User provisioning 4.7.1.2 - Resource provisioning 4.7.1.3 - Guard rails 4.7.1.4 - Security groups 4.7.1.5 - Ticket creation 4.7.1.6 - Escalation 4.7.1.7 - Enabling/disabling services and access 4.7.1.8 - Continuous integration and testing 4.7.1.9 - Integrations and Application programming interfaces (APIs) 4.7.2 - Benefits 4.7.2.1 - Efficiency/time saving 4.7.2.2 - Enforcing baselines 4.7.2.3 - Standard infrastructure configurations 4.7.2.4 - Scaling in a secure manner 4.7.2.5 - Staff retention 4.7.2.6 - Reaction time 4.7.2.7 - Workforce multiplier 4.7.3 - Other considerations	6.5 8.1, 8.9 11.3

	4.7.3.1 - Complexity 4.7.3.2 - Cost 4.7.3.3 - Single point of failure 4.7.3.4 - Technical debt 4.7.3.5 - Ongoing supportability	
4.8	Explain appropriate incident response activities 4.8.1 - Process 4.8.1.1 - Preparation 4.8.1.2 - Detection 4.8.1.3 - Analysis 4.8.1.4 - Containment 4.8.1.5 - Eradication 4.8.1.6 - Recovery 4.8.1.7 - Lessons learned 4.8.2 - Training 4.8.3 - Testing 4.8.3.1 - Tabletop exercise 4.8.3.2 - Simulation 4.8.4 - Root cause analysis 4.8.5 - Threat hunting 4.8.6 - Digital forensics 4.8.6.1 - Legal hold 4.8.6.2 - Chain of custody 4.8.6.3 - Acquisition 4.8.6.4 - Reporting	7.1 9.1, 9.3 13.2

	4.8.6.5 - Preservation 4.8.6.6 - E-discovery	
4.9	Given a scenario, use data sources to support an investigation 4.9.1 - Log data 4.9.1.1 - Firewall logs 4.9.1.2 - Application logs 4.9.1.3 - Endpoint logs 4.9.1.4 - OS-specific security logs 4.9.1.5 - IPS/IDS logs 4.9.1.6 - Network logs 4.9.1.7 - Metadata 4.9.2 - Data sources 4.9.2.1 - Vulnerability scans 4.9.2.2 - Automated reports 4.9.2.3 - Dashboards 4.9.2.4 - Packet captures	6.2, 6.4, 6.5 7.1, 7.2, 7.3 9.2, 9.3 12.3
5.0	**Security Program Management and Oversight**	
5.1	Summarize elements of effective security governance 5.1.1 - Guidelines 5.1.2 - Policies 5.1.2.1 - Acceptable use policy (AUP) 5.1.2.2 - Information security policies 5.1.2.3 - Business continuity 5.1.2.4 - Disaster recovery 5.1.2.5 - Incident response 5.1.2.6 - Software development lifecycle (SDLC)	4.1 5.7, 5.10 7.3 8.9 9.1 10.7 11.1, 11.2 12.1, 12.2, 12.3 13.1, 13.2

- 5.1.2.7 - Change management
- 5.1.3 - Standards
  - 5.1.3.1 - Password
  - 5.1.3.2 - Access control
  - 5.1.3.3 - Physical security
  - 5.1.3.4 - Encryption
- 5.1.4 - Procedures
  - 5.1.4.1 - Change management
  - 5.1.4.2 - Onboarding/offboarding
  - 5.1.4.3 - Playbooks
- 5.1.5 - External considerations
  - 5.1.5.1 - Regulatory
  - 5.1.5.2 - Legal
  - 5.1.5.3 - Industry
  - 5.1.5.4 - Local/regional
  - 5.1.5.5 - National
  - 5.1.5.6 - Global
- 5.1.6 - Monitoring and revision
- 5.1.7 - Types of governance structures
  - 5.1.7.1 - Boards
  - 5.1.7.2 - Committees
  - 5.1.7.3 - Government entities
  - 5.1.7.4 - Centralized/decentralized
- 5.1.8 - Roles and responsibilities for systems and data
  - 5.1.8.1 - Owners

	5.1.8.2 - Controllers 5.1.8.3 - Processors 5.1.8.4 - Custodians/stewards	
5.2	Explain elements of the risk management process 5.2.1 - Risk identification 5.2.2 - Risk assessment 5.2.2.1 - Ad hoc 5.2.2.2 - Recurring 5.2.2.3 - One-time 5.2.2.4 - Continuous 5.2.3 - Risk analysis 5.2.3.1 - Qualitative 5.2.3.2 - Quantitative 5.2.3.3 - Single loss expectancy (SLE) 5.2.3.4 - Annualized loss expectancy (ALE) 5.2.3.5 - Annualized rate of occurrence (ARO) 5.2.3.6 - Probability 5.2.3.7 - Likelihood 5.2.3.8 - Exposure factor 5.2.3.9 - Impact 5.2.4 - Risk register 5.2.4.1 - Key risk indicators 5.2.4.2 - Risk owners 5.2.4.3 - Risk threshold 5.2.5 - Risk tolerance	8.9 11.2 12.1

	5.2.6 - Risk appetite 5.2.6.1 - Expansionary 5.2.6.2 - Conservative 5.2.6.3 - Neutral 5.2.7 - Risk management strategies 5.2.7.1 - Transfer 5.2.7.2 - Accept 5.2.7.2.1 - Exemption 5.2.7.2.2 - Exception 5.2.7.3 - Avoid 5.2.7.4 - Mitigate 5.2.8 - Risk reporting 5.2.9 - Business impact analysis 5.2.9.1 - Recovery time objective (RTO) 5.2.9.2 - Recovery point objective (RPO) 5.2.9.3 - Mean time to repair (MTTR) 5.2.9.4 - Mean time between failures (MTBF)	
5.3	Explain the processes associated with third-party risk assessment and management 5.3.1 - Vendor assessment 5.3.1.1 - Penetration testing 5.3.1.2 - Right-to-audit clause 5.3.1.3 - Evidence of internal audits 5.3.1.4 - Independent assessments 5.3.1.5 - Supply chain analysis 5.3.2 - Vendor selection	7.4 9.4 10.4 12.2 13.2

	5.3.2.1 - Due diligence 5.3.2.2 - Conflict of interest 5.3.3 - Agreement types 5.3.3.1 - Service-level agreement (SLA) 5.3.3.2 - Memorandum of agreement (MOA) 5.3.3.3 - Memorandum of understanding (MOU) 5.3.3.4 - Master service agreement (MSA) 5.3.3.5 - Work order (WO)/statement of work (SOW) 5.3.3.6 - Non-disclosure agreement (NDA) 5.3.3.7 - Business partners agreement (BPA) 5.3.4 - Vendor monitoring 5.3.5 - Questionnaires 5.3.6 - Rules of engagement	
5.4	Summarize elements of effective security compliance 5.4.1 - Compliance reporting 5.4.1.1 - Internal 5.4.1.2 - External 5.4.2 - Consequences of non-compliance 5.4.2.1 - Fines 5.4.2.2 - Sanctions 5.4.2.3 - Reputational damage 5.4.2.4 - Loss of license 5.4.2.5 - Contractual impacts 5.4.3 - Compliance monitoring 5.4.3.1 - Due diligence/care	6.2 13.1, 13.2

	5.4.3.2 - Attestation and acknowledgement 5.4.3.3 - Internal and external 5.4.3.4 - Automation 5.4.4 - Privacy 5.4.4.1 - Legal implications 5.4.4.1.1 - Local/regional 5.4.4.1.2 - National 5.4.4.1.3 - Global 5.4.4.2 - Data subject 5.4.4.3 - Controller vs. processor 5.4.4.4 - Ownership 5.4.4.5 - Data inventory and retention 5.4.4.6 - Right to be forgotten	
5.5	Explain types and purposes of audits and assessments 5.5.1 - Attestation 5.5.2 - Internal 5.5.2.1 - Compliance 5.5.2.2 - Audit committee 5.5.2.3 - Self-assessments 5.5.3 - External 5.5.3.1 - Regulatory 5.5.3.2 - Examinations 5.5.3.3 - Assessment 5.5.3.4 - Independent third-party audit 5.5.4 - Penetration testing	6.2, 6.5 7.4 12.3

	5.5.4.1 - Physical 5.5.4.2 - Offensive 5.5.4.3 - Defensive 5.5.4.4 - Integrated 5.5.4.5 - Known environment 5.5.4.6 - Partially known environment 5.5.4.7 - Unknown environment 5.5.4.8 - Reconnaissance 5.5.4.8.1 - Passive 5.5.4.8.2 - Active	
5.6	Given a scenario, implement security awareness practices 5.6.1 - Phishing 5.6.1.1 - Campaigns 5.6.1.2 - Recognizing a phishing attempt 5.6.1.3 - Responding to reported suspicious messages 5.6.2 - Anomalous behavior recognition 5.6.2.1 - Risky 5.6.2.2 - Unexpected 5.6.2.3 - Unintentional 5.6.3 - User guidance and training 5.6.3.1 - Policy/handbooks 5.6.3.2 - Situational awareness 5.6.3.3 - Insider threat 5.6.3.4 - Password management 5.6.3.5 - Removable media and cables	2.2 6.3, 6.6 7.3 10.9 13.2

	5.6.3.6 - Social engineering 5.6.3.7 - Operational security 5.6.3.8 - Hybrid/remote work environments 5.6.4 - Reporting and monitoring 5.6.4.1 - Initial 5.6.4.2 - Recurring 5.6.5 - Development 5.6.6 - Execution	

A.1.2 Security+ SY0-701 Exam Objectives by Course Section

The Security Pro course covers the following CompTIA Security+ SY0-701 exam objectives:

Section	Title	Objectives
1.0	**Security Concepts**	
1.1	Security Introduction	1.1 Compare and contrast various types of security controls • 1.1.1 - Categories 1.1.1.1 - Technical 1.1.1.2 - Managerial 1.1.1.3 - Operational 1.1.1.4 - Physical 1.2 Summarize fundamental security concepts • 1.2.1 - Confidentiality, Integrity, and Availability (CIA) 2.1 Compare and contrast common threat actors and motivations • 2.1.1 - Threat actors 2.1.1.1 - Nation-state 2.1.1.5 - Organized crime

1.2	Security Controls	1.1 Compare and contrast various types of security controls • 1.1.1 - Categories 1.1.1.1 - Technical 1.1.1.2 - Managerial 1.1.1.3 - Operational 1.1.1.4 - Physical • 1.1.2 - Control types 1.1.2.1 - Preventive 1.1.2.2 - Deterrent 1.1.2.3 - Detective 1.1.2.4 - Corrective 1.1.2.5 - Compensating 1.1.2.6 - Directive
1.3	Use the Simulator	
2.0	**Threats, Vulnerabilities, and Mitigations**	
2.1	Understanding Attacks	2.1 Compare and contrast common threat actors and motivations • 2.1.1 - Threat actors 2.1.1.1 - Nation-state 2.1.1.2 - Unskilled attacker 2.1.1.3 - Hacktivist 2.1.1.4 - Insider threat 2.1.1.5 - Organized crime 2.1.1.6 - Shadow IT • 2.1.2 - Attributes of actors 2.1.2.1 - Internal/external

2.1.2.2 - Resources/funding

2.1.2.3 - Level of sophistication/capability

- 2.1.3 - Motivations

2.1.3.1 - Data exfiltration

2.1.3.2 - Espionage

2.1.3.3 - Service disruption

2.1.3.4 - Blackmail

2.1.3.5 - Financial gain

2.1.3.6 - Philosophical/political beliefs

2.1.3.7- Ethical

2.1.3.8 - Revenge

2.1.3.9 - Disruption/chaos

2.1.3.10 - War

2.2 Explain common threat vectors and attack surfaces

- 2.2.1 - Message-based

2.2.1.1 - Email

2.2.1.2 - Short Message Service (SMS)

2.2.1.3 - Instant messaging (IM)

- 2.2.2 - Image-based
- 2.2.3 - File-based
- 2.2.5 - Removable device
- 2.2.6 - Vulnerable software

2.2.6.1 - Client-based vs. agentless

- 2.2.7 - Unsupported systems and applications
- 2.2.8 - Unsecure networks

2.2.8.1 - Wireless

2.2.8.2 - Wired

		2.2.8.3 - Bluetooth • 2.2.9 - Open service ports • 2.2.10 - Default credentials • 2.2.11 - Supply chain 2.2.11.1 - Managed service providers (MSPs) 2.2.11.2 - Vendors 2.2.11.3 - Suppliers 2.3 Explain various types of vulnerabilities • 2.3.7 - Supply chain 2.3.7.1 - Service provider 2.3.7.2 - Hardware provider 2.3.7.3 - Software provider 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.4 - Application attacks 2.4.4.4 - Privilege escalation 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.8 - Least privilege 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.3 - Attack surface
2.2	Social Engineering	2.1 Compare and contrast common threat actors and motivations • 2.1.1 - Threat actors 2.1.1.2 - Unskilled attacker 2.1.1.4 - Insider threat • 2.1.3 - Motivations

		2.2 Explain common threat vectors and attack surfaces • 2.2.12 - Human vectors/social engineering 2.2.12.1 - Phishing 2.2.12.2 - Vishing 2.2.12.3 - Smishing 2.2.12.4 - Misinformation/disinformation 2.2.12.5 - Impersonation 2.2.12.6 - Business email compromise 2.2.12.7 - Pretexting 2.2.12.8 - Watering hole 2.2.12.9 - Brand impersonation 2.2.12.10 - Typosquatting 5.6 Given a scenario, implement security awareness practices • 5.6.3 - User guidance and training 5.6.3.6 - Social engineering • 5.6.5 - Development
2.3	Malware	2.4 Given a scenario, analyze indicators of malicious activity • 2.4.1 - Malware attacks 2.4.1.1 - Ransomware 2.4.1.2 - Trojan 2.4.1.3 - Worm 2.4.1.4 - Spyware 2.4.1.5 - Bloatware 2.4.1.6 - Virus

		2.4.1.7 - Keylogger 2.4.1.8 - Logic bomb 2.4.1.9 - Rootkit
3.0	**Cryptographic Solutions**	
3.1	Cryptography	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.1 - Public key infrastructure (PKI) 1.4.1.1 - Public key 1.4.1.2 - Private key 1.4.1.3 - Key escrow • 1.4.2 - Encryption 1.4.2.3 - Asymmetric 1.4.2.4 - Symmetric 1.4.2.6 - Algorithms 1.4.2.7 - Key length • 1.4.4 - Obfuscation 1.4.4.1 - Steganography • 1.4.5 - Hashing • 1.4.6 - Salting • 1.4.7 - Digital signatures • 1.4.9 - Blockchain 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.5 - Cryptographic attacks 2.4.5.1 - Downgrade 2.4.5.2 - Collision 2.4.5.3 - Birthday
3.2	Cryptography Implementations	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption

		1.4.2.1.1 - Full-disk 1.4.2.3 - Asymmetric 1.4.2.4 - Symmetric 1.4.2.5 - Key exchange • 1.4.3 - Tools 1.4.3.1 - Trusted Platform Module (TPM) 1.4.3.2 - Hardware security module (HSM) 1.4.3.3 - Key management system 1.4.3.4 - Secure enclave • 1.4.4 - Obfuscation 1.4.4.1 - Steganography • 1.4.5 - Hashing • 1.4.7 - Digital signatures
3.3	Hashing	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption 1.4.2.6 - Algorithms • 1.4.5 - Hashing • 1.4.6 - Salting • 1.4.7 - Digital signatures
3.4	Encryption	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption 1.4.2.1.1 - Full-disk 1.4.2.1.3 - File 1.4.2.1.5 - Database • 1.4.3 - Tools

		1.4.3.1 - Trusted Platform Module (TPM) 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.6 - Encryption
3.5	Public Key Infrastructure	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.1 - Public key infrastructure (PKI) 1.4.1.1 - Public key 1.4.1.2 - Private key 1.4.1.3 - Key escrow • 1.4.7 - Digital signatures • 1.4.11 - Certificates 1.4.11.1 - Certificate authorities 1.4.11.2 - Certificate revocation lists (CRLs) 1.4.11.3 - Online Certificate Status Protocol (OCSP) 1.4.11.4 - Self-signed 1.4.11.5 - Third-party 1.4.11.6 - Root of trust 1.4.11.7 - Certificate signing request (CSR) generation 1.4.11.8 - Wildcard 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.6 - Application security 4.1.6.1 - Input validation 4.1.6.2 - Secure cookies 4.1.6.3 - Static code analysis 4.1.6.4 - Code signing

4.0	Identity and Access Management	
4.1	Access Control Models	1.2 Summarize fundamental security concepts • 1.2.1 - Confidentiality, Integrity, and Availability (CIA) • 1.2.2 - Non-repudiation • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.1 - Authenticating people 1.2.3.2 - Authenticating systems 1.2.3.3 - Authorization models • 1.2.4 - Gap analysis • 1.2.5 - Zero trust 1.2.5.1 - Control plane 1.2.5.1.1 - Adaptive identity 1.2.5.1.2 - Threat scope reduction 1.2.5.1.3 - Policy-driven access control 1.2.5.1.4 - Policy Administrator 1.2.5.1.5 - Policy Engine 1.2.5.2 - Data plane 1.2.5.2.1 - Implicit trust zones 1.2.5.2.2 - Subject/System 1.2.5.2.3 - Policy enforcement point 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.2 - Access control • 2.5.8 - Least privilege 4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts • 4.6.2 - Permission assignments and implications • 4.6.3 - Identity proofing • 4.6.8 - Access controls

		4.6.8.1 - Mandatory 4.6.8.2 - Discretionary 4.6.8.3 - Role-based 4.6.8.4 - Rule-based 4.6.8.5 - Attribute-based 4.6.8.6 - Time-of-day restrictions 4.6.8.7 - Least privilege • 4.6.9 - Multifactor authentication 4.6.9.1.2 - Hard/soft authentication tokens 4.6.9.2 - Factors 4.6.9.2.1 - Something you know 4.6.9.2.2 - Something you have 4.6.9.2.3 - Something you are 4.6.9.2.4 - Somewhere you are 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.2 - Information security policies
4.2	Authentication	1.2 Summarize fundamental security concepts • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.1 - Authenticating people 1.2.3.2 - Authenticating systems 1.2.3.3 - Authorization models 4.6 Given a scenario, implement and maintain identity and access management • 4.6.4 - Federation • 4.6.5 - Single sign-on (SSO)

		4.6.5.1 - Lightweight Directory Access Protocol (LDAP) 4.6.5.2 - Open authorization (OAuth) 4.6.5.3 - Security Assertions Markup Language (SAML) • 4.6.6 - Interoperability • 4.6.7 - Attestation • 4.6.9 - Multifactor authentication 4.6.9.1 - Implementations 4.6.9.1.1 - Biometrics 4.6.9.1.2 - Hard/soft authentication tokens 4.6.9.1.3 - Security keys 4.6.9.2 - Factors 4.6.9.2.1 - Something you know 4.6.9.2.2 - Something you have 4.6.9.2.3 - Something you are 4.6.9.2.4 - Somewhere you are
4.3	Authorization	1.2 Summarize fundamental security concepts • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.3 - Authorization models 1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.4 - Obfuscation 1.4.4.2 - Tokenization 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.2 - Access control 2.5.2.1 - Access control list (ACL) 2.5.2.2 - Permissions

		4.6 Given a scenario, implement and maintain identity and access management • 4.6.2 - Permission assignments and implications • 4.6.5 - Single sign-on (SSO) • 4.6.8 - Access controls 4.6.8.2 - Discretionary
4.4	Active Directory Overview	1.2 Summarize fundamental security concepts • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.1 - Group Policy
4.5	Hardening Authentication	1.2 Summarize fundamental security concepts • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.1 - Authenticating people 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.7 - Indicators 2.4.7.1 - Account lockout 2.4.7.2 - Concurrent session usage 2.4.7.3 - Blocked content 2.4.7.4 - Impossible travel 2.4.7.6 - Resource inaccessibility 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.1 - Group Policy 4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts

		• 4.6.2 - Permission assignments and implications • 4.6.9 - Multifactor authentication 4.6.9.1.3 - Security keys 4.6.9.2.2 - Something you have • 4.6.10 - Password concepts 4.6.10.1 - Password best practices 4.6.10.1.1 - Length 4.6.10.1.2 - Complexity 4.6.10.1.3 - Reuse 4.6.10.1.4 - Expiration 4.6.10.1.5 - Age 4.6.10.2 - Password managers 4.6.10.3 - Passwordless • 4.6.11 - Privileged access management tools 4.6.11.1 - Just-in-time permissions 4.6.11.2 - Password vaulting 4.6.11.3 - Temporal accounts
4.6	Linux Users	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.11 - Hardening techniques 2.5.11.6 - Default password changes 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.6 - Application security 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security

		4.5.4.2 - SELinux 4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts • 4.6.10 - Password concepts 4.6.10.1.3 - Reuse 4.6.10.1.4 - Expiration
4.7	Linux Groups	4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts
4.8	Remote Access	3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 3.2.2.2 - Remote access 3.2.2.3 - Tunneling 3.2.2.3.2 - Internet protocol security (IPSec) 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.5 - Wireless security settings 4.1.5.2 - AAA/Remote Authentication Dial-In User Service (RADIUS)
4.9	Network Authentication	4.6 Given a scenario, implement and maintain identity and access management • 4.6.4 - Federation • 4.6.5 - Single sign-on (SSO) 4.6.5.1 - Lightweight Directory Access Protocol (LDAP) 4.6.5.2 - Open authorization (OAuth) 4.6.5.3 - Security Assertions Markup Language (SAML)
5.0	**Network Architecture**	

5.1	Enterprise Network Architecture	3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts 3.1.1.1 - Cloud 3.1.1.1.1 - Responsibility matrix 3.1.1.1.2 - Hybrid considerations 3.1.1.1.3 - Third-party vendors 3.1.1.2 - Infrastructure as code (IaC) 3.1.1.3 - Serverless 3.1.1.4 - Microservices 3.1.1.5 - Network infrastructure 3.1.1.5.1 - Physical isolation 3.1.1.5.1.1 - Air-gapped 3.1.1.5.2 - Logical segmentation 3.1.1.5.3 - Software-defined networking (SDN) 3.1.1.6 - On-premises 3.1.1.7 - Centralized/decentralized • 3.1.2 - Considerations 3.1.2.1 - Availability 3.1.2.2 - Resilience 3.1.2.3 - Cost 3.1.2.4 - Responsiveness 3.1.2.5 - Scalability 3.1.2.6 - Ease of deployment 3.1.2.7 - Risk transference

		3.1.2.8 - Ease of recovery 3.1.2.9 - Patch availability 3.1.2.10 - Inability to patch 3.1.2.11 - Power 3.1.2.12 - Compute 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.1 - Device placement 3.2.1.2 - Security zones 3.2.1.3 - Attack surface 3.2.1.4 - Connectivity 3.2.1.5 - Failure modes 3.2.1.5.1 - Fail-open 3.2.1.5.2 - Fail-closed 3.2.1.6 - Device attribute 3.2.1.6.1 - Active vs. passive 3.2.1.6.2 - Inline vs. tap/monitor 3.2.1.7.4 - Load balancer • 3.2.3 - Selection of effective controls
5.2	Security Appliances	1.2 Summarize fundamental security concepts • 1.2.7 - Deception and disruption technology 1.2.7.1 - Honeypot 1.2.7.2 - Honeynet 1.2.7.3 - Honeyfile 1.2.7.4 - Honeytoken

		3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.2 - Security zones 3.2.1.5 - Failure modes 3.2.1.5.1 - Fail-open 3.2.1.5.2 - Fail-closed 3.2.1.7 - Network appliances 3.2.1.7.1 - Jump server 3.2.1.7.2 - Proxy server 3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS) 3.2.1.7.4 - Load balancer 3.2.1.7.5 - Sensors 3.2.1.9.2 - Unified threat management (UTM) 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.1 - Firewall 4.5.1.4 - Screened subnets • 4.5.2 - IDS/IPS 4.5.2.1 - Trends 4.5.2.2 - Signatures • 4.5.3 - Web filter 4.5.3.1 - Agent-based 4.5.3.2 - Centralized proxy 4.5.3.3 - Universal Resource Locator (URL) scanning

		4.5.3.4 - Content categorization 4.5.3.5 - Block rules 4.5.3.6 - Reputation • 4.5.6 - DNS filtering
5.3	Screened Subnets	3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.1 - Firewall 4.5.1.4 - Screened subnets
5.4	Firewalls	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.11 - Hardening techniques 2.5.11.3 - Host-based firewall 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.9 - Firewall types 3.2.1.9.1 - Web application firewall (WAF) 3.2.1.9.2 - Unified threat management (UTM) 3.2.1.9.3 - Next-generation firewall (NGFW) 3.2.1.9.4 - Layer 4/Layer 7 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.1 - Firewall 4.5.1.1 - Rules

		4.5.1.2 - Access lists 4.5.1.3 - Ports/protocols 4.5.1.4 - Screened subnets
5.5	Virtual Private Networks	3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 3.2.2.2 - Remote access 3.2.2.3 - Tunneling 3.2.2.3.1 - Transport Layer Security (TLS) 3.2.2.3.2 - Internet protocol security (IPSec) 3.2.2.4 - Software-defined wide area network (SD-WAN) 3.2.2.5 - Secure access service edge (SASE)
5.6	Network Access Control	4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.10. Network access control (NAC)
5.7	Network Device Vulnerabilities	2.3 Explain various types of vulnerabilities • 2.3.9 - Misconfiguration • 2.3.11 - Zero-day 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.4 - Application attacks 2.4.4.4 - Privilege escalation 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.1 - Segmentation • 2.5.11 - Hardening techniques 2.5.11.6 - Default password changes 4.6 Given a scenario, implement and maintain identity and access management

		• 4.6.1 - Provisioning/de-provisioning user accounts • 4.6.10 - Password concepts 4.6.10.1 - Password best practices 4.6.10.1.1 - Length 4.6.10.1.2 - Complexity 4.6.10.1.3 - Reuse 4.6.10.1.4 - Expiration 4.6.10.1.5 - Age 5.1 Summarize elements of effective security governance • 5.1.3 - Standards 5.1.3.1 - Password
5.8	Network Applications	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.7 - Digital signatures 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan 4.3.1.2 - Application security 4.3.1.2.1 - Static analysis 4.3.1.2.2 - Dynamic analysis 4.3.1.2.3 - Package monitoring • 4.3.3 - Vulnerability response and remediation 4.3.3.1 - Patching
5.9	Switch Security and Attacks	3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations

		3.2.1.8 - Port security 3.2.1.8.1 - 802.1X 3.2.1.8.2 - Extensible Authentication Protocol (EAP) 3.3 Compare and contrast concepts and strategies to protect data • 3.3.4 - Methods to secure data 3.3.4.7 - Segmentation 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.2 - Hardening targets 4.1.2.3 - Switches • 4.1.5 - Wireless security settings 4.1.5.2 - AAA/Remote Authentication Dial-In User Service (RADIUS) 4.1.5.4 - Authentication protocols 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.5 - Implementation of secure protocols
5.10	Router Security	1.1 Compare and contrast various types of security controls • 1.1.1 - Categories 1.1.1.4 - Physical 2.2 Explain common threat vectors and attack surfaces • 2.2.10 - Default credentials 2.3 Explain various types of vulnerabilities • 2.3.4 - Hardware 2.3.4.1 - Firmware 2.5 Explain the purpose of mitigation techniques used to secure the enterprise

		• 2.5.2 - Access control 2.5.2.1 - Access control list (ACL) 2.5.2.2 - Permissions • 2.5.11 - Hardening techniques 2.5.11.5 - Disabling ports/protocols 2.5.11.6 - Default password changes 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.2 - Remote access 3.3 Compare and contrast concepts and strategies to protect data • 3.3.4 - Methods to secure data 3.3.4.7 - Segmentation 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.2 - Hardening targets 4.1.2.4 - Routers 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.5 - Implementation of secure protocols 4.5.5.1 - Protocol selection 5.1 Summarize elements of effective security governance • 5.1.3 - Standards 5.1.3.2 - Access control
6.0	**Resiliency and Site Security**	
6.1	Physical Threats	1.2 Summarize fundamental security concepts • 1.2.6 - Physical security

		1.2.6.1 - Bollards 1.2.6.2 - Access control vestibule 1.2.6.3 - Fencing 1.2.6.4 - Video surveillance 1.2.6.5 - Security guard 1.2.6.6 - Access badge 1.2.6.7 - Lighting 1.2.6.8 - Sensors 1.2.6.8.1 - Infrared 1.2.6.8.2 - Pressure 1.2.6.8.3 - Microwave 1.2.6.8.4 - Ultrasonic 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.2 - Physical attacks 2.4.2.1 - Brute force 2.4.2.2 - Radio frequency identification (RFID) cloning 2.4.2.3 - Environmental 3.4 Explain the importance of resilience and recovery in security architecture • 3.4.9 - Power 4.6 Given a scenario, implement and maintain identity and access management • 4.6.9 - Multifactor authentication 4.6.9.1.1 - Biometrics
6.2	Monitoring and Reconnaissance	2.2 Explain common threat vectors and attack surfaces • 2.2.8 - Unsecure networks • 2.2.9 - Open service ports

2.5 Explain the purpose of mitigation techniques used to secure the enterprise

- 2.5.7 - Monitoring

4.1 Given a scenario, apply common security techniques to computing resources

- 4.1.8. Monitoring

4.3 Explain various activities associated with vulnerability management

- 4.3.1 - Identification methods
    - 4.3.1.3.1 - Open-source intelligence (OSINT)

4.4 Explain security alerting and monitoring concepts and tools

- 4.4.1 - Monitoring computing resources
    - 4.4.1.1 - Systems
    - 4.4.1.3 - Infrastructure
- 4.4.3 - Tools
    - 4.4.3.6 - Vulnerability scanners

4.5 Given a scenario, modify enterprise capabilities to enhance security

- 4.5.1 - Firewall
    - 4.5.1.3 - Ports/protocols

4.9 Given a scenario, use data sources to support an investigation

- 4.9.2 - Data sources
    - 4.9.2.4 - Packet captures

5.4 Summarize elements of effective security compliance

- 5.4.3 - Compliance monitoring

5.5 Explain types and purposes of audits and assessments

- 5.5.2 - Internal

		5.5.2.1 - Compliance • 5.5.4 - Penetration testing 5.5.4.8 - Reconnaissance 5.5.4.8.1 - Passive 5.5.4.8.2 - Active
6.3	Intrusion Detection	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.11 - Hardening techniques 2.5.11.4 - Host-based intrusion prevention system (HIPS) 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.6.2 - Inline vs. tap/monitor 3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS) 3.2.1.7.5 - Sensors 4.3 Explain various activities associated with vulnerability management • 4.3.2 - Analysis 4.3.2.1 - Confirmation 4.3.2.1.1 - False positive 4.3.2.1.2 - False negative 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.2 - IDS/IPS 4.5.2.1 - Trends 4.5.2.2 - Signatures

		• 4.5.12. User behavior analytics 5.6 Given a scenario, implement security awareness practices • 5.6.2 - Anomalous behavior recognition 5.6.2.2 - Unexpected
6.4	Protocol Analyzers	2.4 Given a scenario, analyze indicators of malicious activity • 2.4.3 - Network attacks 2.4.3.4 - On-path 2.4.3.5 - Credential replay 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.11 - Hardening techniques 2.5.11.5 - Disabling ports/protocols 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.8. Monitoring 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.1 - Firewall 4.5.1.3 - Ports/protocols • 4.5.5 - Implementation of secure protocols 4.9 Given a scenario, use data sources to support an investigation • 4.9.2 - Data sources 4.9.2.4 - Packet captures
6.5	Analyzing Network Attacks	2.1 Compare and contrast common threat actors and motivations • 2.1.3 - Motivations 2.1.3.1 - Data exfiltration 2.4 Given a scenario, analyze indicators of malicious activity

		• 2.4.3 - Network attacks 2.4.3.1 - Distributed denial-of-service (DDoS) 2.4.3.1.1 - Amplified 2.4.3.1.2 - Reflected 2.4.3.2 - Domain Name System (DNS) attacks 2.4.3.3 - Wireless 2.4.3.4 - On-path 2.4.3.5 - Credential replay 2.4.3.6 - Malicious code • 2.4.4 - Application attacks 2.4.4.4 - Privilege escalation 4.7 Explain the importance of automation and orchestration related to secure operations • 4.7.1 - Use cases of automation and scripting 4.9 Given a scenario, use data sources to support an investigation • 4.9.2 - Data sources 4.9.2.4 - Packet captures 5.5 Explain types and purposes of audits and assessments • 5.5.4 - Penetration testing 5.5.4.8 - Reconnaissance
6.6	Analyzing Password Attacks	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.5 - Hashing • 1.4.6 - Salting 2.2 Explain common threat vectors and attack surfaces • 2.2.10 - Default credentials • 2.2.12 - Human vectors/social engineering

		2.4 Given a scenario, analyze indicators of malicious activity • 2.4.6 - Password attacks 2.4.6.1 - Spraying 2.4.6.2 - Brute force 5.6 Given a scenario, implement security awareness practices • 5.6.3 - User guidance and training 5.6.3.4 - Password management
7.0	**Vulnerability Management**	
7.1	Vulnerability Management	1.1 Compare and contrast various types of security controls • 1.1.2 - Control types 1.1.2.5 - Compensating 2.3 Explain various types of vulnerabilities • 2.3.2 - Operating system (OS)-based • 2.3.4 - Hardware 2.3.4.1 - Firmware 2.3.4.2 - End-of-life 2.3.4.3 - Legacy 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan 4.3.1.3 - Threat feed 4.3.1.3.1 - Open-source intelligence (OSINT) 4.3.1.3.2 - Proprietary/third-party 4.3.1.3.3 - Information-sharing organization 4.3.1.3.4 - Dark web

		4.3.1.4 - Penetration testing 4.3.1.5 - Responsible disclosure program 4.3.1.5.1 - Bug bounty program 4.3.1.6 - System/process audit • 4.3.2 - Analysis 4.3.2.1 - Confirmation 4.3.2.2 - Prioritize 4.3.2.3 - Common Vulnerability Scoring System (CVSS) 4.3.2.4 - Common Vulnerability Enumeration (CVE) 4.3.2.5 - Vulnerability classification 4.3.2.6 - Exposure factor 4.3.2.7 - Environmental variables 4.3.2.8 - Industry/organizational impact 4.3.2.9 - Risk tolerance • 4.3.3 - Vulnerability response and remediation 4.3.3.1 - Patching 4.3.3.2 - Insurance 4.3.3.3 - Segmentation 4.3.3.4 - Compensating controls 4.3.3.5 - Exceptions and exemptions • 4.3.4 - Validation of remediation 4.3.4.1 - Rescanning 4.3.4.2 - Audit 4.3.4.3 - Verification 4.4 Explain security alerting and monitoring concepts and tools

		• 4.4.3 - Tools 4.4.3.6 - Vulnerability scanners 4.8 Explain appropriate incident response activities • 4.8.5 - Threat hunting 4.9 Given a scenario, use data sources to support an investigation • 4.9.2 - Data sources 4.9.2.1 - Vulnerability scans
7.2	Vulnerability Scanning	2.2 Explain common threat vectors and attack surfaces • 2.2.6 - Vulnerable software 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan 4.3.1.2 - Application security 4.3.1.2.1 - Static analysis 4.3.1.2.2 - Dynamic analysis 4.3.1.2.3 - Package monitoring • 4.3.2 - Analysis 4.3.2.4 - Common Vulnerability Enumeration (CVE) 4.3.2.5 - Vulnerability classification 4.4 Explain security alerting and monitoring concepts and tools • 4.4.1 - Monitoring computing resources 4.4.1.1 - Systems 4.4.1.2 - Applications 4.4.1.3 - Infrastructure • 4.4.2 - Activities

		4.4.2.3 - Scanning 4.4.2.4 - Reporting • 4.4.3 - Tools 4.4.3.6 - Vulnerability scanners 4.9 Given a scenario, use data sources to support an investigation • 4.9.2 - Data sources 4.9.2.3 - Dashboards
7.3	Alerting and Monitoring	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.4 - Obfuscation 1.4.4.2 - Tokenization 1.4.4.3 - Data masking 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.7 - Monitoring 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.7.5 - Sensors 3.3 Compare and contrast concepts and strategies to protect data • 3.3.3 - General data considerations 3.3.3.1.1 - Data at rest 3.3.3.1.2 - Data in transit 3.3.3.1.3 - Data in use • 3.3.4 - Methods to secure data 3.3.4.2 - Encryption

		3.3.4.4 - Masking 3.3.4.5 - Tokenization 3.3.4.8 - Permission restrictions 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.8. Monitoring 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan 4.4 Explain security alerting and monitoring concepts and tools • 4.4.1 - Monitoring computing resources 4.4.1.1 - Systems 4.4.1.3 - Infrastructure • 4.4.2 - Activities 4.4.2.1 - Log aggregation 4.4.2.2 - Alerting 4.4.2.4 - Reporting 4.4.2.5 - Archiving 4.4.2.6 - Alert response and remediation/validation 4.4.2.6.2 - Alert tuning • 4.4.3 - Tools 4.4.3.1 - Security Content Automation Protocol (SCAP) 4.4.3.2 - Benchmarks 4.4.3.3 - Agents/agentless

		4.4.3.3.1 - Security information and event management (SIEM) 4.4.3.3.2 - Antivirus 4.4.3.3.3 - Data loss prevention (DLP) 4.4.3.4 - Simple Network Management Protocol (SNMP) traps 4.4.3.5 - NetFlow 4.4.3.6 - Vulnerability scanners 4.9 Given a scenario, use data sources to support an investigation • 4.9.1 - Log data 4.9.1.1 - Firewall logs 4.9.1.3 - Endpoint logs 4.9.1.4 - OS-specific security logs 4.9.1.5 - IPS/IDS logs 4.9.1.6 - Network logs • 4.9.2 - Data sources 4.9.2.3 - Dashboards 5.1 Summarize elements of effective security governance • 5.1.4 - Procedures 5.1.4.3 - Playbooks 5.6 Given a scenario, implement security awareness practices • 5.6.4 - Reporting and monitoring
7.4	Penetration Testing	2.2 Explain common threat vectors and attack surfaces • 2.2.12 - Human vectors/social engineering 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods

		4.3.1.3.1 - Open-source intelligence (OSINT) 4.3.1.4 - Penetration testing 4.3.1.5.1 - Bug bounty program 4.4 Explain security alerting and monitoring concepts and tools • 4.4.3 - Tools 4.4.3.6 - Vulnerability scanners 5.3 Explain the processes associated with third-party risk assessment and management • 5.3.3 - Agreement types 5.3.3.5 - Work order (WO)/statement of work (SOW) • 5.3.6 - Rules of engagement 5.5 Explain types and purposes of audits and assessments • 5.5.4 - Penetration testing 5.5.4.1 - Physical 5.5.4.2 - Offensive 5.5.4.3 - Defensive 5.5.4.4 - Integrated 5.5.4.5 - Known environment 5.5.4.6 - Partially known environment 5.5.4.7 - Unknown environment 5.5.4.8 - Reconnaissance 5.5.4.8.1 - Passive 5.5.4.8.2 - Active
8.0	**Network and Endpoint Security**	

8.1	Operating System Hardening	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption 1.4.2.1.1 - Full-disk 2.2 Explain common threat vectors and attack surfaces • 2.2.5 - Removable device 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.2 - Access control • 2.5.3 - Application allow list • 2.5.5 - Patching • 2.5.6 - Encryption • 2.5.7 - Monitoring • 2.5.8 - Least privilege • 2.5.9 - Configuration enforcement • 2.5.10 - Decommissioning • 2.5.11 - Hardening techniques 2.5.11.2 - Installation of endpoint protection 2.5.11.3 - Host-based firewall 2.5.11.5 - Disabling ports/protocols 2.5.11.6 - Default password changes 2.5.11.7 - Removal of unnecessary software 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.1 - Secure baselines 4.1.1.1 - Establish 4.1.1.2 - Deploy 4.1.1.3 - Maintain • 4.1.2 - Hardening targets 4.1.2.2 - Workstations

		4.3 Explain various activities associated with vulnerability management • 4.3.3 - Vulnerability response and remediation 4.3.3.1 - Patching 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.1 - Group Policy 4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts • 4.6.8 - Access controls 4.6.8.7 - Least privilege • 4.6.9 - Multifactor authentication 4.7 Explain the importance of automation and orchestration related to secure operations • 4.7.1 - Use cases of automation and scripting 4.7.1.4 - Security groups
8.2	File Server Security	1.2 Summarize fundamental security concepts • 1.2.6 - Physical security 1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption 1.4.2.1.1 - Full-disk 1.4.2.1.3 - File 2.2 Explain common threat vectors and attack surfaces • 2.2.3 - File-based 2.5 Explain the purpose of mitigation techniques used to secure the enterprise

- 2.5.2 - Access control
    - 2.5.2.1 - Access control list (ACL)
    - 2.5.2.2 - Permissions
- 2.5.8 - Least privilege
- 2.5.11 - Hardening techniques
    - 2.5.11.7 - Removal of unnecessary software

3.2 Given a scenario, apply security principles to secure enterprise infrastructure

- 3.2.2 - Secure communication/access
    - 3.2.2.1 - Virtual private network (VPN)
        - 3.2.2.3.2 - Internet protocol security (IPSec)

4.1 Given a scenario, apply common security techniques to computing resources

- 4.1.2 - Hardening targets
    - 4.1.2.6 - Servers

4.2 Explain the security implications of proper hardware, software, and data asset management

- 4.2.1 - Acquisition/procurement process

4.3 Explain various activities associated with vulnerability management

- 4.3.1 - Identification methods
    - 4.3.1.6 - System/process audit

4.5 Given a scenario, modify enterprise capabilities to enhance security

- 4.5.5 - Implementation of secure protocols
- 4.5.8. File integrity monitoring

4.6 Given a scenario, implement and maintain identity and access management

- 4.6.1 - Provisioning/de-provisioning user accounts
- 4.6.8 - Access controls

		4.6.8.7 - Least privilege
8.3	Linux Host Security	2.2 Explain common threat vectors and attack surfaces • 2.2.5 - Removable device 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.5 - Patching • 2.5.11 - Hardening techniques 2.5.11.3 - Host-based firewall 2.5.11.4 - Host-based intrusion prevention system (HIPS) 2.5.11.5 - Disabling ports/protocols 2.5.11.7 - Removal of unnecessary software
8.4	Wireless Overview	4.1 Given a scenario, apply common security techniques to computing resources • 4.1.3. Wireless devices 4.1.3.1 - Installation considerations 4.1.3.1.1 - Site surveys 4.1.3.1.2 - Heat maps • 4.1.5 - Wireless security settings 4.1.5.1 - Wi-Fi Protected Access 3 (WPA3) 4.1.5.2 - AAA/Remote Authentication Dial-In User Service (RADIUS)
8.5	Wireless Attacks	2.2 Explain common threat vectors and attack surfaces • 2.2.8 - Unsecure networks 2.2.8.1 - Wireless 2.2.8.3 - Bluetooth 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.2 - Physical attacks

		2.4.2.2 - Radio frequency identification (RFID) cloning • 2.4.3 - Network attacks 2.4.3.3 - Wireless 2.4.3.5 - Credential replay 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.3. Wireless devices 4.1.3.1 - Installation considerations • 4.1.5 - Wireless security settings 4.1.5.1 - Wi-Fi Protected Access 3 (WPA3) 4.1.5.4 - Authentication protocols
8.6	Wireless Defenses	2.2 Explain common threat vectors and attack surfaces • 2.2.8 - Unsecure networks 2.2.8.1 - Wireless • 2.2.10 - Default credentials 2.3 Explain various types of vulnerabilities • 2.3.4 - Hardware 2.3.4.1 - Firmware 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.11 - Hardening techniques 2.5.11.6 - Default password changes 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS)

		3.2.1.8 - Port security 3.2.1.8.1 - 802.1X 3.2.1.8.2 - Extensible Authentication Protocol (EAP) • 3.2.2 - Secure communication/access 3.2.2.3.1 - Transport Layer Security (TLS) 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.3. Wireless devices 4.1.3.1 - Installation considerations • 4.1.5 - Wireless security settings 4.1.5.1 - Wi-Fi Protected Access 3 (WPA3) 4.1.5.2 - AAA/Remote Authentication Dial-In User Service (RADIUS) 4.1.5.3 - Cryptographic protocols 4.1.5.4 - Authentication protocols
8.7	Data Transmission Security	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.2 - Encryption 1.4.2.2 - Transport/communication 1.4.2.3 - Asymmetric 1.4.2.5 - Key exchange • 1.4.11 - Certificates 1.4.11.1 - Certificate authorities 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.3 - Network attacks 2.4.3.2 - Domain Name System (DNS) attacks

		3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 3.2.2.2 - Remote access 3.2.2.3 - Tunneling 3.2.2.3.1 - Transport Layer Security (TLS) 3.2.2.3.2 - Internet protocol security (IPSec)
8.8	Web Application Security	2.3 Explain various types of vulnerabilities • 2.3.1 - Application 2.3.1.1 - Memory injection 2.3.1.2 - Buffer overflow 2.3.1.3 - Race conditions 2.3.1.3.1 - Time-of-check (TOC) 2.3.1.3.2 - Time-of-use (TOU) 2.3.1.4 - Malicious update • 2.3.3 - Web-based 2.3.3.1 - Structured Query Language injection (SQLi) 2.3.3.2 - Cross-site scripting (XSS) • 2.3.4 - Hardware • 2.3.11 - Zero-day 2.4 Given a scenario, analyze indicators of malicious activity • 2.4.3 - Network attacks 2.4.3.5 - Credential replay • 2.4.4 - Application attacks 2.4.4.1 - Injection

		2.4.4.2 - Buffer overflow 2.4.4.3 - Replay 2.4.4.4 - Privilege escalation 2.4.4.5 - Forgery 2.4.4.6 - Directory traversal 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.5 - Patching 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS) 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.6 - Application security 4.1.6.2 - Secure cookies 4.6 Given a scenario, implement and maintain identity and access management • 4.6.5 - Single sign-on (SSO) 4.6.5.1 - Lightweight Directory Access Protocol (LDAP)
8.9	Application Development and Security	1.3 Explain the importance of change management processes and the impact to security • 1.3.4 -Version control 2.2 Explain common threat vectors and attack surfaces • 2.2.7 - Unsupported systems and applications 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.2 - Access control

2.5.2.2 - Permissions

- 2.5.3 - Application allow list
- 2.5.5 - Patching
- 2.5.7 - Monitoring
- 2.5.11 - Hardening techniques

2.5.11.2 - Installation of endpoint protection

2.5.11.3 - Host-based firewall

2.5.11.7 - Removal of unnecessary software

3.3 Compare and contrast concepts and strategies to protect data

- 3.3.4 - Methods to secure data

3.3.4.6 - Obfuscation

4.1 Given a scenario, apply common security techniques to computing resources

- 4.1.1 - Secure baselines

4.1.1.1 - Establish

- 4.1.6 - Application security

4.1.6.1 - Input validation

4.1.6.2 - Secure cookies

4.1.6.3 - Static code analysis

4.1.6.4 - Code signing

- 4.1.7. Sandboxing

4.3 Explain various activities associated with vulnerability management

- 4.3.1 - Identification methods

4.3.1.2 - Application security

4.3.1.2.1 - Static analysis

4.3.1.2.2 - Dynamic analysis

		4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.2 - SELinux 4.6 Given a scenario, implement and maintain identity and access management • 4.6.1 - Provisioning/de-provisioning user accounts • 4.6.8 - Access controls 4.6.8.7 - Least privilege 4.7 Explain the importance of automation and orchestration related to secure operations • 4.7.1 - Use cases of automation and scripting 4.7.1.1 - User provisioning 4.7.1.2 - Resource provisioning 4.7.1.4 - Security groups 4.7.1.5 - Ticket creation 4.7.1.7 - Enabling/disabling services and access 4.7.1.9 - Integrations and Application programming interfaces (APIs) • 4.7.2 - Benefits 4.7.2.1 - Efficiency/time saving 4.7.2.2 - Enforcing baselines 4.7.2.5 - Staff retention • 4.7.3 - Other considerations 4.7.3.1 - Complexity 4.7.3.2 - Cost 4.7.3.3 - Single point of failure

		4.7.3.4 - Technical debt 4.7.3.5 - Ongoing supportability 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.6 - Software development lifecycle (SDLC) 5.2 Explain elements of the risk management process • 5.2.3 - Risk analysis 5.2.3.8 - Exposure factor
9.0	**Incident Response**	
9.1	Incident Response and Mitigation	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.1 - Segmentation • 2.5.4 - Isolation 4.8 Explain appropriate incident response activities • 4.8.1 - Process 4.8.1.1 - Preparation 4.8.1.2 - Detection 4.8.1.3 - Analysis 4.8.1.4 - Containment 4.8.1.5 - Eradication 4.8.1.6 - Recovery 4.8.1.7 - Lessons learned 5.1 Summarize elements of effective security governance • 5.1.4 - Procedures 5.1.4.3 - Playbooks
9.2	Log Management	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.7 - Monitoring

3.2 Given a scenario, apply security principles to secure enterprise infrastructure

- 3.2.1 - Infrastructure considerations

    3.2.1.7.3 - Intrusion prevention system (IPS)/intrusion detection system (IDS)

    3.2.1.7.5 - Sensors

4.1 Given a scenario, apply common security techniques to computing resources

- 4.1.1 - Secure baselines

    4.1.1.1 - Establish

4.3 Explain various activities associated with vulnerability management

- 4.3.1 - Identification methods

    4.3.1.1 - Vulnerability scan

- 4.3.2 - Analysis

    4.3.2.4 - Common Vulnerability Enumeration (CVE)

4.4 Explain security alerting and monitoring concepts and tools

- 4.4.2 - Activities

    4.4.2.1 - Log aggregation

    4.4.2.2 - Alerting

- 4.4.3 - Tools

    4.4.3.3.1 - Security information and event management (SIEM)

    4.4.3.5 - NetFlow

    4.4.3.6 - Vulnerability scanners

4.9 Given a scenario, use data sources to support an investigation

- 4.9.1 - Log data

		4.9.1.1 - Firewall logs 4.9.1.2 - Application logs 4.9.1.3 - Endpoint logs 4.9.1.4 - OS-specific security logs 4.9.1.5 - IPS/IDS logs 4.9.1.6 - Network logs 4.9.1.7 - Metadata • 4.9.2 - Data sources 4.9.2.3 - Dashboards 4.9.2.4 - Packet captures
9.3	Digital Forensics	4.8 Explain appropriate incident response activities • 4.8.6 - Digital forensics 4.8.6.1 - Legal hold 4.8.6.2 - Chain of custody 4.8.6.3 - Acquisition 4.8.6.4 - Reporting 4.8.6.5 - Preservation 4.8.6.6 - E-discovery 4.9 Given a scenario, use data sources to support an investigation • 4.9.2 - Data sources 4.9.2.1 - Vulnerability scans 4.9.2.3 - Dashboards 4.9.2.4 - Packet captures
9.4	Redundancy	3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts

		3.1.1.1.3 - Third-party vendors 3.1.1.5 - Network infrastructure 3.1.1.14 - High availability • 3.1.2 - Considerations 3.1.2.11 - Power 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.6.1 - Active vs. passive 3.2.1.7.4 - Load balancer 3.4 Explain the importance of resilience and recovery in security architecture • 3.4.1 - High availability 3.4.1.1 - Load balancing vs. clustering • 3.4.2 - Site considerations 3.4.2.4 - Geographic dispersion • 3.4.9 - Power 3.4.9.1 - Generators 3.4.9.2 - Uninterruptible power supply (UPS) 5.3 Explain the processes associated with third-party risk assessment and management • 5.3.2 - Vendor selection
9.5	Backup and Restore	3.4 Explain the importance of resilience and recovery in security architecture • 3.4.8 - Backups 3.4.8.1 - Onsite/offsite 3.4.8.2 - Frequency

		3.4.8.3 - Encryption 3.4.8.4 - Snapshots 3.4.8.5 - Recovery 3.4.8.6 - Replication 3.4.8.7 - Journaling
10.0	**Protocol, App, and Cloud Security**	
10.1	Host Virtualization	2.3 Explain various types of vulnerabilities • 2.3.5 - Virtualization 2.3.5.1 - Virtual machine (VM) escape 2.3.5.2 - Resource reuse 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.1 - Segmentation 3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts 3.1.1.5 - Network infrastructure 3.1.1.5.2 - Logical segmentation 3.1.1.8 - Containerization 3.1.1.9 - Virtualization 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.1 - Infrastructure considerations 3.2.1.7.4 - Load balancer 3.4 Explain the importance of resilience and recovery in security architecture • 3.4.1 - High availability

		3.4.1.1 - Load balancing vs. clustering 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.7. Sandboxing 4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.1 - Vulnerability scan
10.2	Virtual Networking	3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts 3.1.1.5 - Network infrastructure 3.1.1.9 - Virtualization 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.1 - Virtual private network (VPN) 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.7. Sandboxing
10.3	Software-Defined Networking	3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts 3.1.1.5.3 - Software-defined networking (SDN)
10.4	Cloud Services	1.2 Summarize fundamental security concepts • 1.2.3 - Authentication, Authorization, and Accounting (AAA) 1.2.3.1 - Authenticating people 2.2 Explain common threat vectors and attack surfaces • 2.2.11 - Supply chain

2.2.11.1 - Managed service providers (MSPs)

2.2.11.2 - Vendors

2.2.11.3 - Suppliers

2.3 Explain various types of vulnerabilities

- 2.3.6 - Cloud-specific
- 2.3.7 - Supply chain

2.3.7.1 - Service provider

3.1 Compare and contrast security implications of different architecture models

- 3.1.1 - Architecture and infrastructure concepts

3.1.1.1 - Cloud

3.1.1.1.2 - Hybrid considerations

3.1.1.1.3 - Third-party vendors

3.1.1.3 - Serverless

3.1.1.9 - Virtualization

- 3.1.2 - Considerations

3.4 Explain the importance of resilience and recovery in security architecture

- 3.4.4 - Multi-cloud systems

4.1 Given a scenario, apply common security techniques to computing resources

- 4.1.2 - Hardening targets

4.1.2.5 - Cloud infrastructure

5.3 Explain the processes associated with third-party risk assessment and management

- 5.3.1 - Vendor assessment

5.3.1.1 - Penetration testing

		5.3.1.2 - Right-to-audit clause 5.3.1.4 - Independent assessments • 5.3.4 - Vendor monitoring
10.5	Mobile Devices	2.3 Explain various types of vulnerabilities • 2.3.10 - Mobile device 2.3.10.1 - Side loading 2.3.10.2 - Jailbreaking 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.3 - Application allow list • 2.5.11 - Hardening techniques 2.5.11.1 - Encryption 3.3 Compare and contrast concepts and strategies to protect data • 3.3.4 - Methods to secure data 3.3.4.2 - Encryption 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.1 - Secure baselines 4.1.1.1 - Establish 4.1.1.2 - Deploy • 4.1.2 - Hardening targets 4.1.2.1 - Mobile devices • 4.1.3. Wireless devices 4.1.3.1 - Installation considerations • 4.1.4 - Mobile solutions 4.1.4.1 - Mobile device management (MDM) 4.1.4.2 - Deployment models

		4.1.4.2.1 - Bring your own device (BYOD) 4.1.4.2.2 - Corporate-owned, personally enabled (COPE) 4.1.4.2.3 - Choose your own device (CYOD) 4.1.4.3 - Connections methods 4.1.4.3.1 - Cellular 4.1.4.3.2 - Wi-Fi 4.1.4.3.3 - Bluetooth • 4.1.6 - Application security 4.1.6.4 - Code signing • 4.1.7. Sandboxing 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.1 - Group Policy 4.6 Given a scenario, implement and maintain identity and access management • 4.6.10 - Password concepts 4.6.10.2 - Password managers
10.6	Mobile Device Management	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.3 - Application allow list 3.1 Compare and contrast security implications of different architecture models • 3.1.2 - Considerations 3.1.2.6 - Ease of deployment 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.4 - Mobile solutions

		4.1.4.1 - Mobile device management (MDM) 4.1.4.2 - Deployment models 4.1.4.2.1 - Bring your own device (BYOD) 4.2 Explain the security implications of proper hardware, software, and data asset management • 4.2.3 - Disposal/decommissioning 4.2.3.1 - Sanitization 4.2.3.2 - Destruction 4.2.3.4 - Data retention
10.7	BYOD Security	2.2 Explain common threat vectors and attack surfaces • 2.2.8 - Unsecure networks 2.2.8.1 - Wireless 2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.4 - Isolation 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.2 - Hardening targets 4.1.2.1 - Mobile devices • 4.1.3. Wireless devices 4.1.3.1 - Installation considerations • 4.1.4 - Mobile solutions 4.1.4.1 - Mobile device management (MDM) 4.1.4.2 - Deployment models 4.1.4.2.1 - Bring your own device (BYOD) 4.1.4.2.2 - Corporate-owned, personally enabled (COPE)

		4.1.4.2.3 - Choose your own device (CYOD) 4.1.4.3.2 - Wi-Fi 4.1.4.3.3 - Bluetooth 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.10. Network access control (NAC) 4.6 Given a scenario, implement and maintain identity and access management • 4.6.8 - Access controls 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.1 - Acceptable use policy (AUP)
10.8	Embedded and Specialized Systems	1.4 Explain the importance of using appropriate cryptographic solutions • 1.4.3 - Tools 1.4.3.1 - Trusted Platform Module (TPM) 2.2 Explain common threat vectors and attack surfaces • 2.2.8 - Unsecure networks 2.2.8.1 - Wireless 2.2.8.2 - Wired 2.2.8.3 - Bluetooth 3.1 Compare and contrast security implications of different architecture models • 3.1.1 - Architecture and infrastructure concepts 3.1.1.10 - IoT 3.1.1.11 - Industrial control systems (ICS)/supervisory control and data acquisition (SCADA) 3.1.1.12 - Real-time operating system (RTOS)

		3.1.1.13 - Embedded systems 3.3 Compare and contrast concepts and strategies to protect data • 3.3.4 - Methods to secure data 3.3.4.2 - Encryption 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.2 - Hardening targets 4.1.2.1 - Mobile devices 4.1.2.7 - ICS/SCADA 4.1.2.8 - Embedded systems 4.1.2.10 - IoT devices • 4.1.4 - Mobile solutions 4.1.4.3.1 - Cellular 4.1.4.3.2 - Wi-Fi 4.1.4.3.3 - Bluetooth
10.9	Email	2.4 Given a scenario, analyze indicators of malicious activity • 2.4.1 - Malware attacks 2.4.1.6 - Virus • 2.4.4 - Application attacks 3.2 Given a scenario, apply security principles to secure enterprise infrastructure • 3.2.2 - Secure communication/access 3.2.2.3.1 - Transport Layer Security (TLS) 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.6 - Application security 4.1.6.2 - Secure cookies

		4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.7 - Email security 4.5.7.1 - Domain-based Message Authentication Reporting and Conformance (DMARC) 4.5.7.2 - DomainKeys Identified Mail (DKIM) 4.5.7.3 - Sender Policy Framework (SPF) 4.5.7.4 - Gateway • 4.5.9. DLP 5.6 Given a scenario, implement security awareness practices • 5.6.1 - Phishing
11.0	**Security Governance Concepts**	
11.1	Policies, Standards, and Procedures	4.6 Given a scenario, implement and maintain identity and access management • 4.6.9 - Multifactor authentication • 4.6.10 - Password concepts 4.6.10.1.1 - Length 4.6.10.1.2 - Complexity 4.6.10.1.3 - Reuse 4.6.10.1.4 - Expiration 5.1 Summarize elements of effective security governance • 5.1.1 - Guidelines • 5.1.2 - Policies 5.1.2.1 - Acceptable use policy (AUP) 5.1.2.2 - Information security policies 5.1.2.3 - Business continuity 5.1.2.4 - Disaster recovery

		5.1.2.5 - Incident response 5.1.2.6 - Software development lifecycle (SDLC) 5.1.2.7 - Change management • 5.1.3 - Standards 5.1.3.1 - Password 5.1.3.2 - Access control 5.1.3.3 - Physical security 5.1.3.4 - Encryption • 5.1.4 - Procedures 5.1.4.3 - Playbooks • 5.1.5 - External considerations 5.1.5.1 - Regulatory 5.1.5.2 - Legal 5.1.5.3 - Industry 5.1.5.4 - Local/regional 5.1.5.5 - National 5.1.5.6 - Global • 5.1.6 - Monitoring and revision • 5.1.7 - Types of governance structures 5.1.7.1 - Boards 5.1.7.2 - Committees 5.1.7.3 - Government entities 5.1.7.4 - Centralized/decentralized
11.2	Change Management	1.3 Explain the importance of change management processes and the impact to security • 1.3.2 - Technical implications

		1.3.2.1 - Allow lists/deny lists 1.3.2.2 - Restricted activities 1.3.2.3 - Downtime 1.3.2.4 - Service restart 1.3.2.5 - Application restart 1.3.2.6 - Legacy applications 1.3.2.7 - Dependencies • 1.3.3 - Documentation 1.3.3.1 - Updating diagrams 1.3.3.2 - Updating policies/procedures • 1.3.4 -Version control 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.7 - Change management • 5.1.4 - Procedures 5.1.4.1 - Change management • 5.1.7 - Types of governance structures 5.1.7.1 - Boards 5.2 Explain elements of the risk management process • 5.2.3 - Risk analysis
11.3	Automation and Orchestration	4.7 Explain the importance of automation and orchestration related to secure operations • 4.7.1 - Use cases of automation and scripting 4.7.1.5 - Ticket creation 4.7.1.7 - Enabling/disabling services and access

		4.7.1.8 - Continuous integration and testing • 4.7.2 - Benefits 4.7.2.1 - Efficiency/time saving 4.7.2.2 - Enforcing baselines 4.7.2.3 - Standard infrastructure configurations 4.7.2.5 - Staff retention 4.7.2.6 - Reaction time 4.7.2.7 - Workforce multiplier • 4.7.3 - Other considerations 4.7.3.1 - Complexity 4.7.3.2 - Cost 4.7.3.3 - Single point of failure 4.7.3.4 - Technical debt 4.7.3.5 - Ongoing supportability
12.0	**Risk Management Processes**	
12.1	Risk Management Processes and Concepts	3.4 Explain the importance of resilience and recovery in security architecture • 3.4.1 - High availability • 3.4.2 - Site considerations 3.4.2.1 - Hot 3.4.2.2 - Cold 3.4.2.3 - Warm 3.4.2.4 - Geographic dispersion • 3.4.3 - Platform diversity • 3.4.4 - Multi-cloud systems • 3.4.5 - Continuity of operations • 3.4.6 - Capacity planning

		3.4.6.1 - People 3.4.6.2 - Technology 3.4.6.3 - Infrastructure • 3.4.7 - Testing 3.4.7.1 - Tabletop exercises 3.4.7.2 - Fail over 3.4.7.3 - Simulation 3.4.7.4 - Parallel processing • 3.4.8 - Backups 4.2 Explain the security implications of proper hardware, software, and data asset management • 4.2.2 - Assignment/accounting 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.3 - Business continuity 5.1.2.5 - Incident response 5.2 Explain elements of the risk management process • 5.2.1 - Risk identification • 5.2.2 - Risk assessment 5.2.2.1 - Ad hoc 5.2.2.2 - Recurring 5.2.2.3 - One-time 5.2.2.4 - Continuous • 5.2.3 - Risk analysis 5.2.3.1 - Qualitative

		5.2.3.2 - Quantitative 5.2.3.3 - Single loss expectancy (SLE) 5.2.3.4 - Annualized loss expectancy (ALE) 5.2.3.5 - Annualized rate of occurrence (ARO) 5.2.3.6 - Probability 5.2.3.7 - Likelihood 5.2.3.8 - Exposure factor 5.2.3.9 - Impact • 5.2.4 - Risk register 5.2.4.1 - Key risk indicators 5.2.4.2 - Risk owners 5.2.4.3 - Risk threshold • 5.2.5 - Risk tolerance • 5.2.6 - Risk appetite 5.2.6.1 - Expansionary 5.2.6.2 - Conservative 5.2.6.3 - Neutral • 5.2.7 - Risk management strategies 5.2.7.1 - Transfer 5.2.7.2 - Accept 5.2.7.2.1 - Exemption 5.2.7.2.2 - Exception 5.2.7.3 - Avoid 5.2.7.4 - Mitigate • 5.2.8 - Risk reporting • 5.2.9 - Business impact analysis

		5.2.9.1 - Recovery time objective (RTO) 5.2.9.2 - Recovery point objective (RPO) 5.2.9.3 - Mean time to repair (MTTR) 5.2.9.4 - Mean time between failures (MTBF)
12.2	Vendor Management	5.1 Summarize elements of effective security governance • 5.1.4 - Procedures 5.1.4.2 - Onboarding/offboarding 5.3 Explain the processes associated with third-party risk assessment and management • 5.3.1 - Vendor assessment 5.3.1.1 - Penetration testing 5.3.1.2 - Right-to-audit clause 5.3.1.3 - Evidence of internal audits 5.3.1.4 - Independent assessments 5.3.1.5 - Supply chain analysis • 5.3.2 - Vendor selection 5.3.2.1 - Due diligence 5.3.2.2 - Conflict of interest • 5.3.3 - Agreement types 5.3.3.1 - Service-level agreement (SLA) 5.3.3.2 - Memorandum of agreement (MOA) 5.3.3.3 - Memorandum of understanding (MOU) 5.3.3.4 - Master service agreement (MSA) 5.3.3.5 - Work order (WO)/statement of work (SOW) 5.3.3.6 - Non-disclosure agreement (NDA)

		5.3.3.7 - Business partners agreement (BPA) • 5.3.4 - Vendor monitoring • 5.3.5 - Questionnaires • 5.3.6 - Rules of engagement
12.3	Audits and Assessments	4.3 Explain various activities associated with vulnerability management • 4.3.1 - Identification methods 4.3.1.6 - System/process audit • 4.3.4 - Validation of remediation 4.3.4.2 - Audit 4.4 Explain security alerting and monitoring concepts and tools • 4.4.2 - Activities 4.4.2.1 - Log aggregation 4.5 Given a scenario, modify enterprise capabilities to enhance security • 4.5.4 - Operating system security 4.5.4.1 - Group Policy 4.9 Given a scenario, use data sources to support an investigation • 4.9.1 - Log data 4.9.1.4 - OS-specific security logs 4.9.1.6 - Network logs 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.2 - Information security policies 5.5 Explain types and purposes of audits and assessments • 5.5.1 - Attestation • 5.5.2 - Internal 5.5.2.1 - Compliance

		5.5.2.2 - Audit committee 5.5.2.3 - Self-assessments • 5.5.3 - External 5.5.3.1 - Regulatory 5.5.3.2 - Examinations 5.5.3.3 - Assessment 5.5.3.4 - Independent third-party audit
13.0	**Data Protection and Compliance**	
13.1	Data Classification and Compliance	3.3 Compare and contrast concepts and strategies to protect data • 3.3.1 - Data types 3.3.1.1 - Regulated 3.3.1.2 - Trade secret 3.3.1.3 - Intellectual property 3.3.1.4 - Legal information 3.3.1.5 - Financial information 3.3.1.6 - Human and non-human readable • 3.3.2 - Data classifications 3.3.2.1 - Sensitive 3.3.2.2 - Confidential 3.3.2.3 - Public 3.3.2.4 - Restricted 3.3.2.5 - Private 3.3.2.6 - Critical • 3.3.3 - General data considerations 3.3.3.2 - Data sovereignty

4.2 Explain the security implications of proper hardware, software, and data asset management

- 4.2.3 - Disposal/decommissioning
    - 4.2.3.1 - Sanitization
    - 4.2.3.2 - Destruction
    - 4.2.3.3 - Certification
    - 4.2.3.4 - Data retention

5.1 Summarize elements of effective security governance

- 5.1.8 - Roles and responsibilities for systems and data
    - 5.1.8.2 - Controllers
    - 5.1.8.3 - Processors

5.4 Summarize elements of effective security compliance

- 5.4.2 - Consequences of non-compliance
    - 5.4.2.1 - Fines
    - 5.4.2.2 - Sanctions
    - 5.4.2.3 - Reputational damage
    - 5.4.2.4 - Loss of license
    - 5.4.2.5 - Contractual impacts
- 5.4.4 - Privacy
    - 5.4.4.1 - Legal implications
        - 5.4.4.1.1 - Local/regional
        - 5.4.4.1.2 - National
        - 5.4.4.1.3 - Global
    - 5.4.4.2 - Data subject
    - 5.4.4.3 - Controller vs. processor

		5.4.4.4 - Ownership 5.4.4.5 - Data inventory and retention 5.4.4.6 - Right to be forgotten
13.2	Personnel Policies	2.5 Explain the purpose of mitigation techniques used to secure the enterprise • 2.5.8 - Least privilege 3.3 Compare and contrast concepts and strategies to protect data • 3.3.1 - Data types 3.3.1.1 - Regulated 3.3.1.3 - Intellectual property 3.3.1.4 - Legal information 3.3.1.5 - Financial information • 3.3.2 - Data classifications • 3.3.3 - General data considerations 3.3.3.1 - Data states 3.3.3.1.1 - Data at rest 3.3.3.1.2 - Data in transit 3.3.3.1.3 - Data in use 3.3.3.2 - Data sovereignty 3.3.3.3 - Geolocation • 3.3.4 - Methods to secure data 3.3.4.2 - Encryption 4.1 Given a scenario, apply common security techniques to computing resources • 4.1.4 - Mobile solutions 4.1.4.2.1 - Bring your own device (BYOD)

		4.2 Explain the security implications of proper hardware, software, and data asset management • 4.2.3 - Disposal/decommissioning 4.2.3.4 - Data retention 4.4 Explain security alerting and monitoring concepts and tools • 4.4.3 - Tools 4.4.3.3.3 - Data loss prevention (DLP) 4.6 Given a scenario, implement and maintain identity and access management • 4.6.8 - Access controls 4.6.8.7 - Least privilege 4.8 Explain appropriate incident response activities • 4.8.2 - Training • 4.8.6 - Digital forensics 4.8.6.1 - Legal hold 5.1 Summarize elements of effective security governance • 5.1.2 - Policies 5.1.2.1 - Acceptable use policy (AUP) • 5.1.4 - Procedures 5.1.4.2 - Onboarding/offboarding 5.3 Explain the processes associated with third-party risk assessment and management • 5.3.2 - Vendor selection 5.3.2.1 - Due diligence 5.4 Summarize elements of effective security compliance • 5.4.4 - Privacy 5.4.4.1 - Legal implications

		5.4.4.5 - Data inventory and retention 5.6 Given a scenario, implement security awareness practices • 5.6.1 - Phishing 5.6.1.2 - Recognizing a phishing attempt • 5.6.2 - Anomalous behavior recognition 5.6.2.1 - Risky 5.6.2.2 - Unexpected 5.6.2.3 - Unintentional • 5.6.3 - User guidance and training 5.6.3.1 - Policy/handbooks 5.6.3.2 - Situational awareness 5.6.3.5 - Removable media and cables 5.6.3.6 - Social engineering • 5.6.4 - Reporting and monitoring 5.6.4.1 - Initial 5.6.4.2 - Recurring • 5.6.5 - Development

A.1.3 How to take the Security+ SY0-701 Exam

The Security+ SY0-701 exam is scheduled through Pearson VUE.

Certification	Provider	Website	Customer Service
CompTIA	Pearson VUE	pearsonvue.com	Online Chat and phone numbers by region are available on pearsonvue.com/comptia/contact

The Security+ SY0-701 exam information web page on CompTIA's website provides the latest details on how to schedule the exam.

TestOut is pleased to offer students a 10% off coupon code for exam vouchers purchased from CompTIA's online marketplace.

To purchase a voucher, go to the CompTIA website and complete the following:

Select your desired ***certification*** .

Add the corresponding ***CompTIA voucher(s)*** to your shopping cart.

Enter the coupon code **TESTOUT10** at checkout to get 10% off your purchase.

Go to the Pearson VUE website.

Enter your ***voucher information*** to register for the certification.

A.1.4 Security+ SY0-701 FAQs

Where do I take an exam?

When you schedule the exam with Pearson VUE, you will be presented with options to take the exam at a local testing center or your home or office. If you choose a local testing center, you will be given the option to pick from the testing centers closest to your location.

What do I bring to the exam?

You will need two forms of identification, one with a picture. For example, you could use a driver's license and a credit card. You will typically receive an erasable marker and whiteboard or laminated paper to use during the exam. Notes or other reference materials are not allowed inside the testing center. It is recommended that you do not bring personal items to the testing center; however, a testing center typically provides a locker to store personal items.

What specific information do I need to know to pass the exam?

People often ask, "What is on the exam?" This course is intended to help you gain the knowledge, skills, and abilities necessary to perform the corresponding job roles. Additionally, we highly recommend that you use the certification practice exam to prepare for the Security+ SY0-701 exam.

The questions on certification exams are protected to maintain the integrity of the exam. While the practice exam does not include the exact questions, it will help measure your understanding of the topics covered in the CompTIA objectives. You should review the Security+ SY0-701 exam objectives and make sure you are comfortable with each topic and objective listed. After you take the practice exam, the objectives for the exam are listed on the Report screen. You can use the report to focus your studies to prepare for the exam.

Is there a student discount for the Security+ SY0-701 exam?

CompTIA does offer discounts on its exam vouchers. Also, academic pricing for students is available through the academic store. Check the exam information page and www.comptia.org/blog/voucher-discount for more information.

TestOut is pleased to offer students a 10% off coupon code for exam vouchers purchased from CompTIA's online marketplace.

Is the Security+ SY0-701 exam an adaptive exam?

The Security+ SY0-701 exam and the certification practice exam are not adaptive tests. The certification practice exam is the best way to prepare for taking the certification exam. The content of the objectives for an exam is more comprehensive than any single adaptive test. Adaptive tests are too short to give you a thorough review and the chance to practice taking the test. You need to understand all of the questions before you take the certification exam.

An adaptive exam begins by giving you an easy-to-moderate question. If you answer the question correctly, it gives you a more difficult question. With each correct answer, the difficulty of the next question increases. On the other hand, if you answer the second question incorrectly, the next questions will be easier. The test changes the question difficulty until it determines your skill level.

There are two primary characteristics you will notice as you take an adaptive exam:

- You cannot skip questions or review previously answered questions. This means that you need to take more time to answer each question carefully before going on to the next question. Adaptive exams display a warning screen at the beginning of the exam stating that you will not be allowed to review previous questions.

- Adaptive tests are typically shorter than traditional exams. The current adaptive exams range between 15 and 35 questions.

How is the exam administered?

Certification exams are all computer-based. At the beginning of the exam, you will have an opportunity to view a tutorial on the exam software. Time spent reviewing the tutorial does not count towards the time you have to take the exam.

What types of questions are on the exam?

The Security+ SY0-701 exam has mostly multiple-choice questions. Additionally, there are a few performance-based questions at the start of the exam and some drag-and-drop activities. The CompTIA website provides sample questions and information on performance-based questions.

How many questions are on an exam, and how long do I have to complete it?

The Security+ SY0-701 exam has a maximum of 90 questions and 90 minutes to complete the exam.

How soon after I take the exam will I know whether I have passed it?

You will receive results as soon as you have completed the exam. The testing program provides immediate feedback and automatically generates a report showing the required passing score and your score. Pick up your exam report before you leave the testing center. You should keep this report in case there are any discrepancies in your certification program.

If I do not pass the exam, can I retake it?

For the Security+ SY0-701 exam, see the CompTIA website for exam policies. Typically, there is no waiting period before attempting to retake the exam a second time; however, the 3rd and subsequent attempts have a waiting period. See the CompTIA website for specific information on the retake policy.

A.1.5 Hints and Tips for taking the Security+ SY0-701 Exam

Follow these tips to make your exam experience less stressful and more successful:

When	Tips
Before the Exam	Before you take the exam, try these tips: Prepare a short review sheet for the exam. It should contain reference tables and information that you have trouble remembering. Shortly before you start the exam, study your notes as a last-minute review. Arrive 20 minutes early and relax for a few minutes before the exam. Take a deep breath. Look at the review sheet one last time. You will make fewer mistakes if you are not tense and rushed. Before the exam starts, review the exam tutorial to familiarize yourself with the exam. The time you spend on the orientation exam does not count toward the test time. If you have any questions, ask the exam administrator before the exam begins. The exam is timed, so make sure you ask questions before the test begins.
During the Exam	Once the exam has started: If you are unsure of a question's answer, eliminate the obviously incorrect answers first. Eliminating the obvious makes it easier for you to try to select the correct answer, especially if you have to guess. If you do not know, guess! Be sure you answer all of the questions before you finish. Unanswered questions are wrong and scored as incorrect answers. If you are unsure of an answer, make an educated guess. There is no extra penalty for incorrect answers. If you have time, review your answers before going on to the next question. A word of caution: be absolutely sure before you change an answer! If you are positive that your answer is wrong, change it. But if you are not sure and cannot explain to yourself why you need to change an answer, leave it. Most of the time, your first instinct is correct.
Use Scratch Pad	You will be given an erasable marker and a whiteboard or laminated paper to use during the exam. Follow these tips for using the scratch pad: Immediately after the exam starts, write down anything that could be a useful reference during the exam. This is the time to remember what you studied on your review sheet.

	The information on the review sheet should be fresh in your mind, because you just did a quick review. Write lists, reference tables, and any other vital information on the paper. Do not spend a lot of time, just a minute or two writing down reference material. The list of information will save you time as you answer the questions. While answering questions, use the scratch pad to draw diagrams. A question may be easier to answer after you see a diagram.
Retake an Exam	If you do not pass the exam: Use the score report on your transcript to identify the areas to focus further study. Think carefully about the exam and make notes about the questions that you could not answer. Do this as soon as possible after taking the exam. Look up the correct answers in your study materials. You may get the same or similar questions the next time. Do not wait too long to retake the exam. You already know much of the material, and you may forget what you know if you wait too long.

A.2 CompTIA Security+ Domain Review (20 Questions)

This section contains five domain practice reviews related to the CompTIA Security+ SY0-701 domains.

The domain practices:

- Have 20 questions per domain review
- Are randomly generated
- Have no time limit
- Are not pass/fail
- Have a percentage score at the end of the session

This section is meant to be used as a practice review only, not as a graded assignment. If a graded assignment is needed, use the CompTIA Security+ SY0-701 Certification Practice Exam score.

With these study questions, you can:

- Check your answers as you go to obtain immediate feedback.
- Skip questions, return to previous questions, and mark questions for later review.
- Repeat questions as many times as needed.

After you finish the study questions, you can:

- Review each question by selecting the Individual Responses option.

Expand questions marked as incorrect to see the correct answer and an accompanying explanation.

Print the score report to use for further review.

A.2.1 Security+ SY0-701 Domain 1: General Security Concepts (Section Quiz)

A.2.2 Security+ SY0-701 Domain 2: Threats, Vulnerabilities, and Mitigations (Section Quiz)

A.2.3 Security+ SY0-701 Domain 3: Security Architecture (Section Quiz)

A.2.4 Security+ SY0-701 Domain 4: Security Operations (Section Quiz)

A.2.5 Security+ SY0-701 Domain 5: Security Program Management and Oversight (Section Quiz)

A.3 CompTIA Security+ Domain Review (All Questions)

This section contains all the TestOut practice questions related to the Security+ SY0-701 exam. Use these questions to prepare yourself for the Security+ SY0-701 exam.

The questions in this section are not randomly generated. You will receive the same set of questions each time you open a new practice session.

This practice review has:

1374 questions

No time limit

No pass/fail

A percentage score at the end of the session

This section is meant to be used as a practice review only, not as a graded assignment. If a graded assignment is needed, use the Security+ SY0-701 Certification Practice Exam score.

With these study questions, you can:

Check your answers as you go to obtain immediate feedback.

Skip questions, return to previous questions, and mark questions for later review.

Repeat questions as many times as needed.

After you finish the study questions, you can:

Review each question by selecting the Individual Responses option.

Expand questions marked as incorrect to see the correct answer and an explanation of the correct answer.

Print the score report to use for further review.

A.3.1 Security+ SY0-701 Domain 1: General Security Concepts (Section Quiz)

A.3.2 Security+ SY0-701 Domain 2: Threats, Vulnerabilities, and Mitigations (Section Quiz)

A.3.3 Security+ SY0-701 Domain 3: Security Architecture (Section Quiz)

A.3.4 Security+ SY0-701 Domain 4: Security Operations (Section Quiz)

A.3.5 Security+ SY0-701 Domain 5: Security Program Management and Oversight (Section Quiz)

A.4 CompTIA Security+ SY0-701 Certification Practice Exam (Section Quiz)

B.0 TestOut Security Pro - Practice Exams

B.1 Prepare for TestOut Security Pro Certification

It is important to prepare for an exam by studying the course material, practicing skills, and committing new concepts to memory. You can use the instructions and tests in this course to help you prepare more efficiently.

We recommend that you take the following steps as you prepare for the TestOut Security Pro Certification exam:

Step	Description
Study the course material	The course materials include text lessons, demonstrations, video lessons, and hands-on labs. As you work through the course, follow these hints for the effective study: Review the learning and exam objectives on each section page. The objectives outline the knowledge and skills you will need for the official certification exam. Watch the videos. Watch the demonstrations. Read all text lesson fact pages. Practice the tasks in the lab simulations until you feel comfortable with your ability to complete them. Avoid skipping any sections unless you can easily pass the Practice Questions at the end of each section. Even if you already know the material, a review can always be helpful when preparing for an exam.
Review the certification exam domains and objectives	Review the domains and objectives for the TestOut Security Pro Certification provided in this section.
Take the domain practice exams	The domain practice exams group the performance-based labs by domain and help assess your understanding of a particular TestOut Security Pro Certification domain and the corresponding objectives.
Take the certification practice exam	After you are confident with your ability to complete the labs, take the certification practice exam to assess your preparedness to take the certification exam. This exam has roughly the same number of questions and time limit as the TestOut Security Pro Certification. Practice questions are designed to assess your knowledge as it relates to the exam objectives.

	Based on your practice exam results, review the course material for questions that you missed. Focus your time on understanding the topics covered in the objectives and not on memorizing answers, as the actual certification exam will have a different set of questions. When your practice exam scores are consistently over 95%, and you feel confident in your understanding of the exam objectives and topics, the next step is to take the certification exam.
Schedule and take the certification exam	The TestOut Security Pro Certification is scheduled through LabSim. If you are taking this course through an instructor, contact your instructor to schedule your exam.

B.1.1 Pro Exam Objectives

The Security Pro course and certification exam cover the following TestOut Security Pro objectives:

#	Domain	Module.Section
1.0	**Identity Management and Authentication**	
1.1	Manage identity 1.1.1 Manage Windows local and domain users and groups 1.1.2 Manage Linux users and groups 1.1.3 Manage Active Directory OUs	4.4, 4.6, 4.7 8.1
1.2	Harden authentication 1.2.1 Configure account policies 1.2.2 Manage account password 1.2.3 Secure default and local accounts 1.2.4 Enforce User Account Control (UAC) 1.2.5 Configure and link Group Policy Objects (GPO)	4.4, 4.5, 4.6 8.1 12.3
2.0	**Physical and Network Security**	
2.1	Harden physical access 2.1.1 Implement physical security 2.1.2 Install and configure a security appliance	5.2, 5.3, 5.4 6.1 8.1, 8.3

	2.1.3 Install and configure a firewall 2.1.4 Create and configure a screened subnet 2.1.5 Configure Network Address Translation (NAT)	
2.2	Harden network devices 2.2.1 Configure and access a switch 2.2.2 Configure and access a wireless network 2.2.3 Configure and access a Virtual Private Network (VPN) 2.2.4 Harden a wireless network 2.2.5 Configure router security 2.2.6 Bring Your Own Device (BYOD) security 2.2.7 Create and connect to a Virtual Local Area Network (VLAN)	4.8 5.5, 5.7, 5.9, 5.10 6.2 8.4, 8.5, 8.6 10.5, 10.6, 10.7
3.0	**Host and Application Defense**	
3.1	Harden computer systems 3.1.1 Configure file system inheritance 3.1.2 Configure anti-virus protection 3.1.3 Configure NTFS permissions 3.1.4 Configure Windows Update	2.3 7.1, 7.3 8.1, 8.2
3.2	Implement application defenses 3.2.1 Implement an application allow list 3.2.2 Implement Data Execution Prevention (DEP) 3.2.3 Configure web application security 3.2.4 Configure email filters and settings 3.2.5 Configure browser settings	8.1, 8.7, 8.8, 8.9 10.6, 10.9
3.3	Implement virtualization 3.3.1 Create virtual machines 3.3.2 Create virtual switches	10.1, 10.2
4.0	**Data Security**	

4.1	Protect and Maintain Data files 4.1.1 Perform data backups and recovery 4.1.2 Implement redundancy	9.4, 9.5
4.2	Implement Encryption Technologies 4.2.1 Encrypt data communications 4.2.2 Encrypt files 4.2.3 Manage certificates	3.1, 3.2, 3.3, 3.4, 3.5 7.3 8.2, 8.7
5.0	**Audit and Security Assessment**	
5.1	Implement logging and auditing 5.1.1 Configure advanced audit policy 5.1.2 Enable device logs	7.3 9.2 12.3
5.2	Assessment techniques 5.2.1 Implement intrusion detection 5.2.2 Identify social engineering 5.2.3 Scan for vulnerabilities 5.2.4 Analyze network attacks 5.2.5 Analyze password attacks	2.2 6.3, 6.5, 6.6 7.1, 7.2, 7.4 9.1, 9.2 10.1

B.1.2 Pro Exam Objectives by Course Section

The Security Pro course covers the following TestOut Security Pro exam objectives:

Section	Title	Objectives
1.0	**Security Concepts**	
1.1	Security Introduction	
1.2	Security Controls	
1.3	Use the Simulator	
2.0	**Threats, Vulnerabilities, and Mitigations**	

2.1	Understanding Attacks	
2.2	Social Engineering	5.2 Assessment techniques • 5.2.2 Identify social engineering
2.3	Malware	3.1 Harden computer systems • 3.1.2 Configure anti-virus protection
3.0	**Cryptographic Solutions**	
3.1	Cryptography	4.2 Implement Encryption Technologies • 4.2.1 Encrypt data communications
3.2	Cryptography Implementations	4.2 Implement Encryption Technologies • 4.2.1 Encrypt data communications • 4.2.2 Encrypt files
3.3	Hashing	4.2 Implement Encryption Technologies • 4.2.1 Encrypt data communications
3.4	Encryption	4.2 Implement Encryption Technologies • 4.2.2 Encrypt files
3.5	Public Key Infrastructure	4.2 Implement Encryption Technologies • 4.2.3 Manage certificates
4.0	**Identity and Access Management**	
4.1	Access Control Models	
4.2	Authentication	
4.3	Authorization	
4.4	Active Directory Overview	1.1 Manage identity • 1.1.1 Manage Windows local and domain users and groups • 1.1.3 Manage Active Directory OUs

		1.2 Harden authentication • 1.2.5 Configure and link Group Policy Objects (GPO)
4.5	Hardening Authentication	1.2 Harden authentication • 1.2.1 Configure account policies • 1.2.2 Manage account password • 1.2.3 Secure default and local accounts • 1.2.4 Enforce User Account Control (UAC) • 1.2.5 Configure and link Group Policy Objects (GPO)
4.6	Linux Users	1.1 Manage identity • 1.1.2 Manage Linux users and groups 1.2 Harden authentication • 1.2.2 Manage account password • 1.2.3 Secure default and local accounts
4.7	Linux Groups	1.1 Manage identity • 1.1.2 Manage Linux users and groups
4.8	Remote Access	2.2 Harden network devices • 2.2.3 Configure and access a Virtual Private Network (VPN)
4.9	Network Authentication	
5.0	**Network Architecture**	
5.1	Enterprise Network Architecture	
5.2	Security Appliances	2.1 Harden physical access • 2.1.2 Install and configure a security appliance • 2.1.4 Create and configure a screened subnet
5.3	Screened Subnets	2.1 Harden physical access • 2.1.4 Create and configure a screened subnet

5.4	Firewalls	2.1 Harden physical access • 2.1.3 Install and configure a firewall
5.5	Virtual Private Networks	2.2 Harden network devices • 2.2.3 Configure and access a Virtual Private Network (VPN) • 2.2.4 Harden a wireless network
5.6	Network Access Control	
5.7	Network Device Vulnerabilities	2.2 Harden network devices • 2.2.1 Configure and access a switch
5.8	Network Applications	
5.9	Switch Security and Attacks	2.2 Harden network devices • 2.2.1 Configure and access a switch
5.10	Router Security	2.2 Harden network devices • 2.2.5 Configure router security
6.0	**Resiliency and Site Security**	
6.1	Physical Threats	2.1 Harden physical access • 2.1.1 Implement physical security
6.2	Monitoring and Reconnaissance	2.2 Harden network devices • 2.2.4 Harden a wireless network
6.3	Intrusion Detection	5.2 Assessment techniques • 5.2.1 Implement intrusion detection
6.4	Protocol Analyzers	
6.5	Analyzing Network Attacks	5.2 Assessment techniques • 5.2.4 Analyze network attacks • 5.2.5 Analyze password attacks
6.6	Analyzing Password Attacks	5.2 Assessment techniques • 5.2.2 Identify social engineering • 5.2.5 Analyze password attacks
7.0	**Vulnerability Management**	

7.1	Vulnerability Management	3.1 Harden computer systems • 3.1.4 Configure Windows Update 5.2 Assessment techniques • 5.2.3 Scan for vulnerabilities
7.2	Vulnerability Scanning	5.2 Assessment techniques • 5.2.3 Scan for vulnerabilities
7.3	Alerting and Monitoring	3.1 Harden computer systems • 3.1.2 Configure anti-virus protection 4.2 Implement Encryption Technologies • 4.2.1 Encrypt data communications • 4.2.2 Encrypt files 5.1 Implement logging and auditing • 5.1.2 Enable device logs
7.4	Penetration Testing	5.2 Assessment techniques • 5.2.3 Scan for vulnerabilities
8.0	**Network and Endpoint Security**	
8.1	Operating System Hardening	1.1 Manage identity • 1.1.1 Manage Windows local and domain users and groups

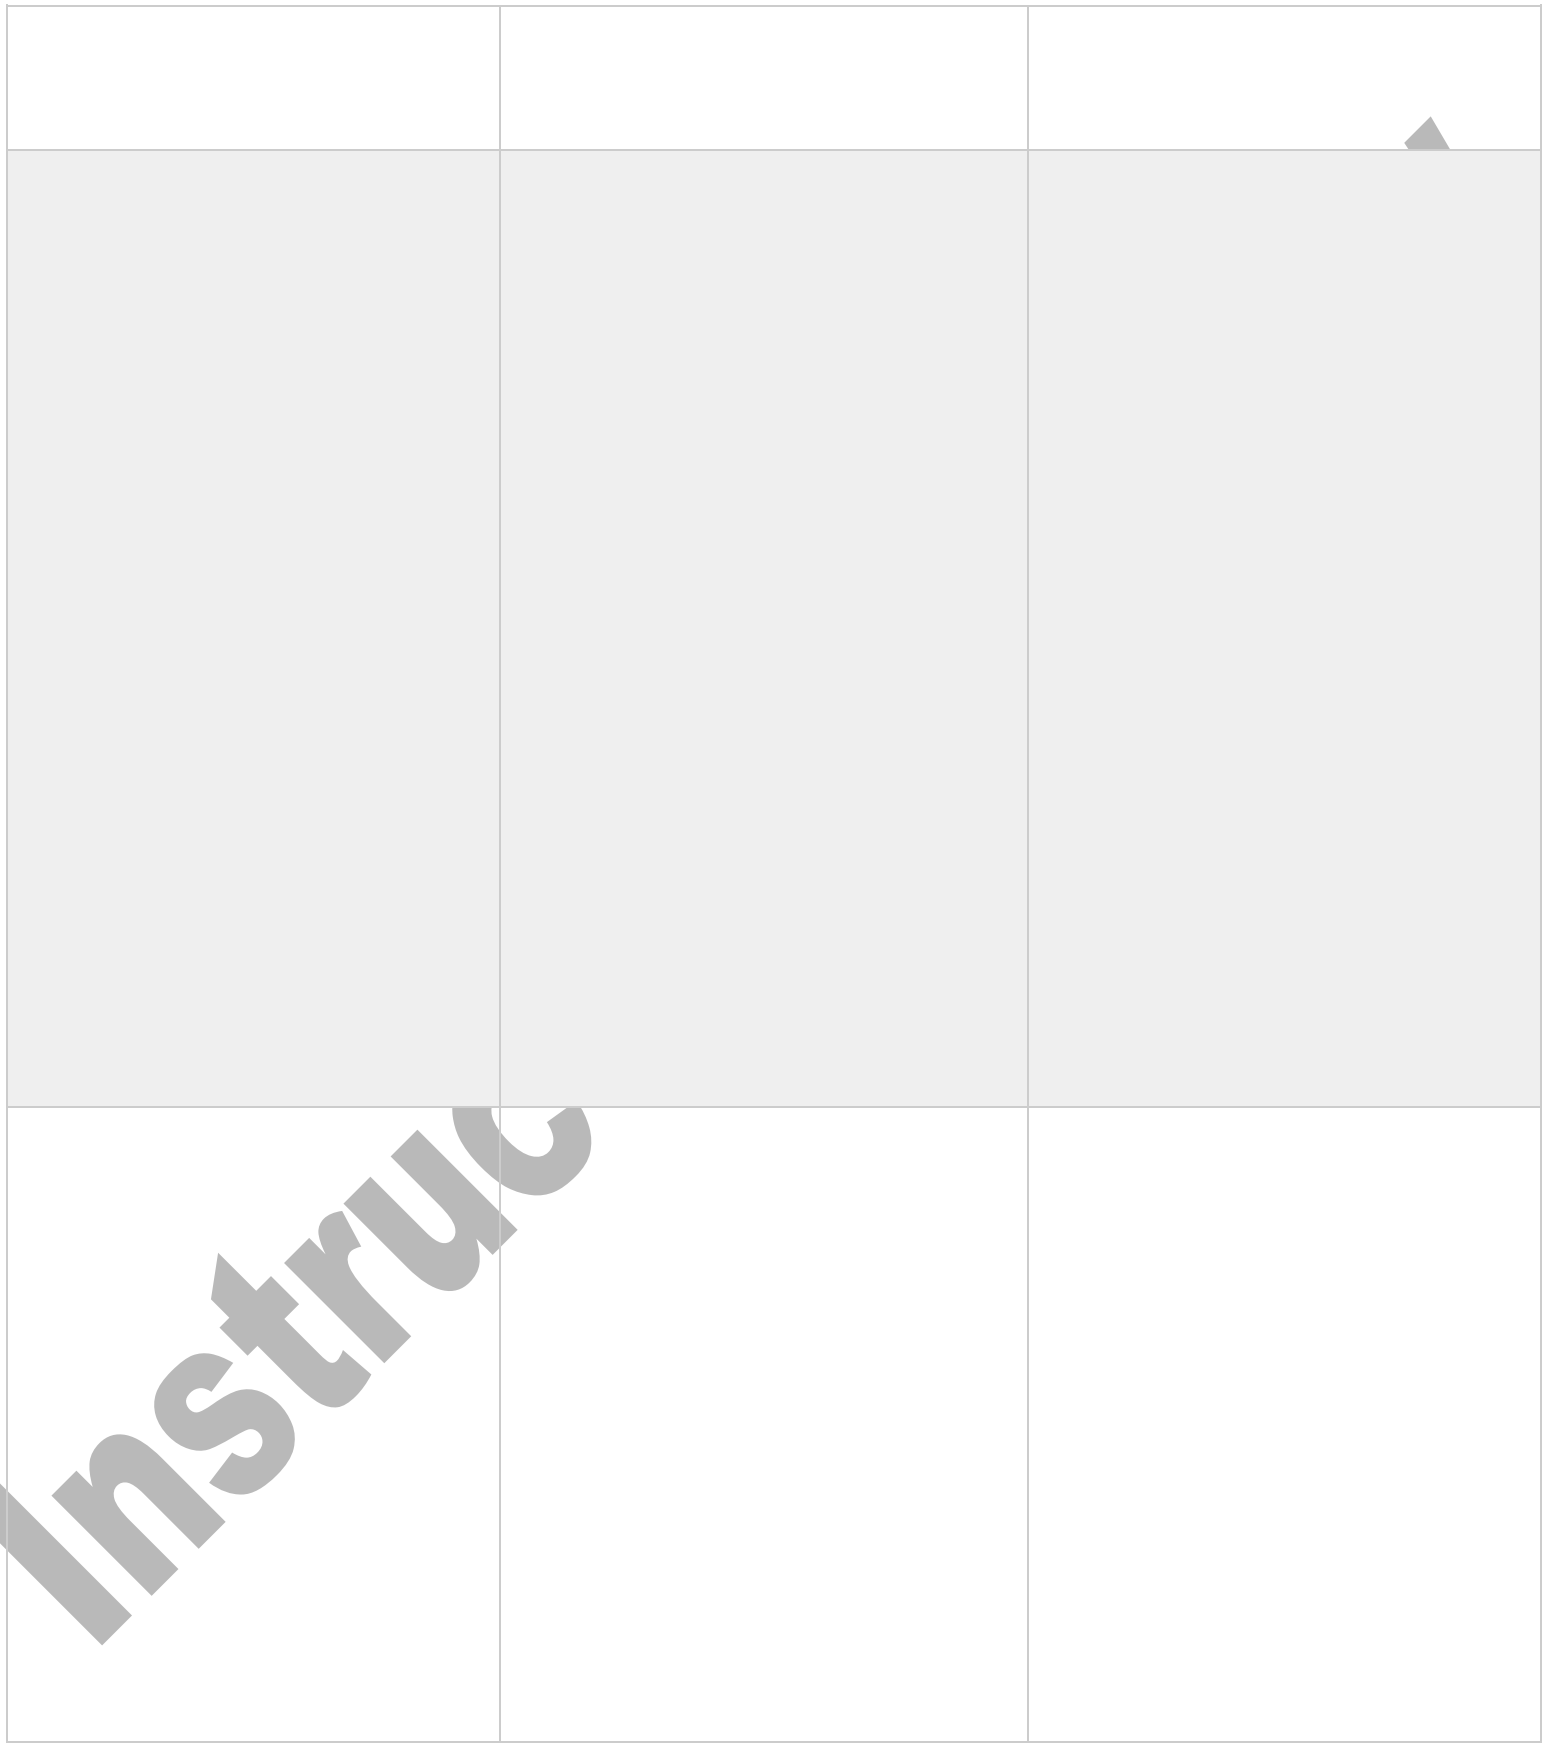
		1.2 Harden authentication • 1.2.5 Configure and link Group Policy Objects (GPO) 2.1 Harden physical access • 2.1.3 Install and configure a firewall 3.1 Harden computer systems • 3.1.2 Configure anti-virus protection • 3.1.4 Configure Windows Update 3.2 Implement application defenses • 3.2.

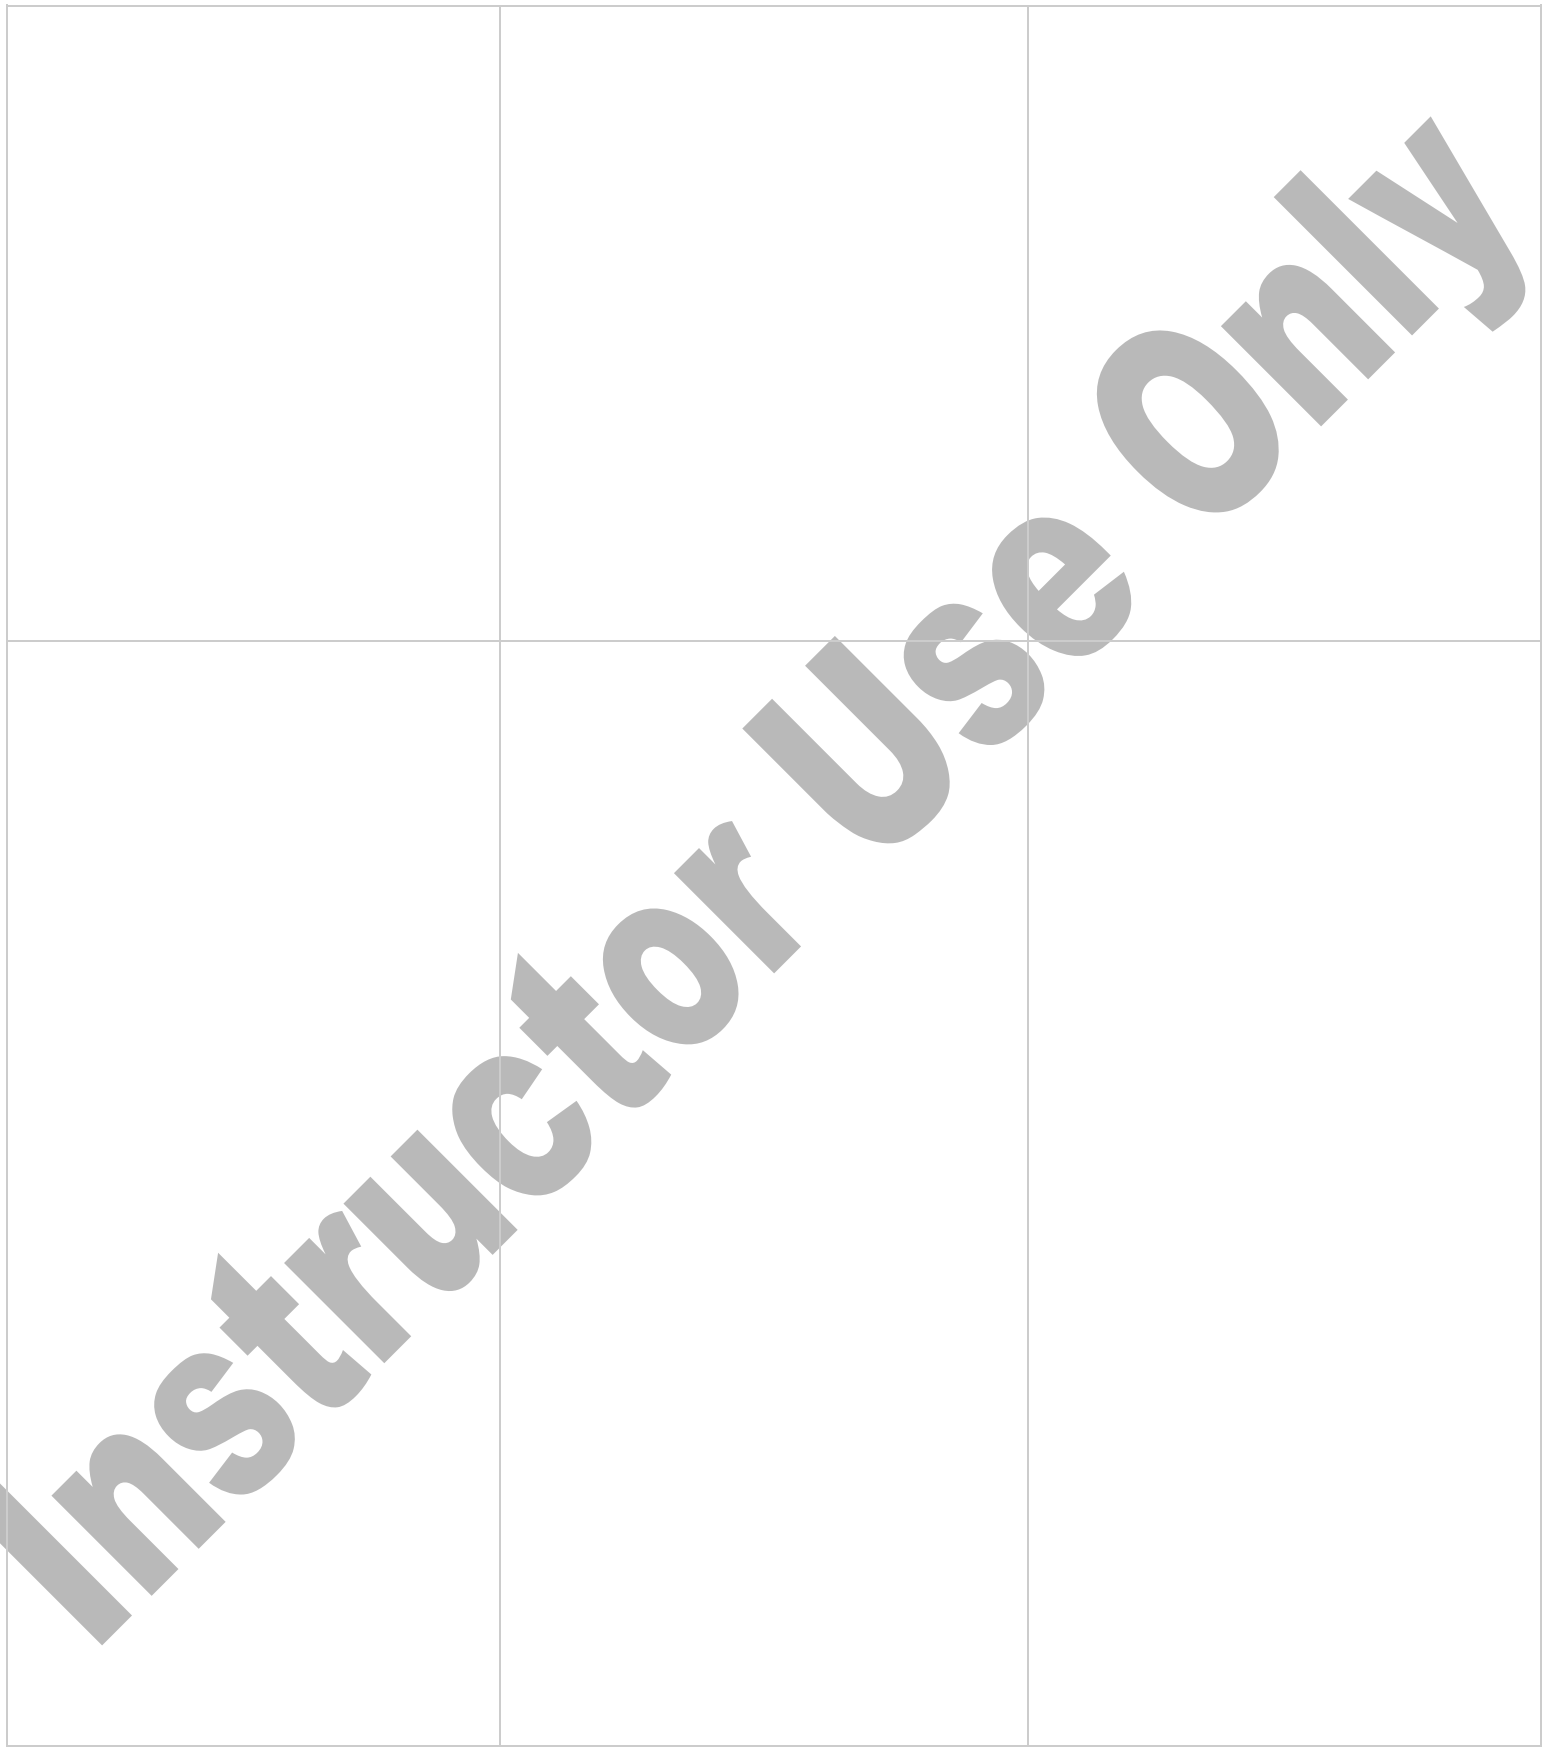
		1 Implement an application allow list
8.2	File Server Security	3.1 Harden computer systems • 3.1.1 Configure file system inheritance

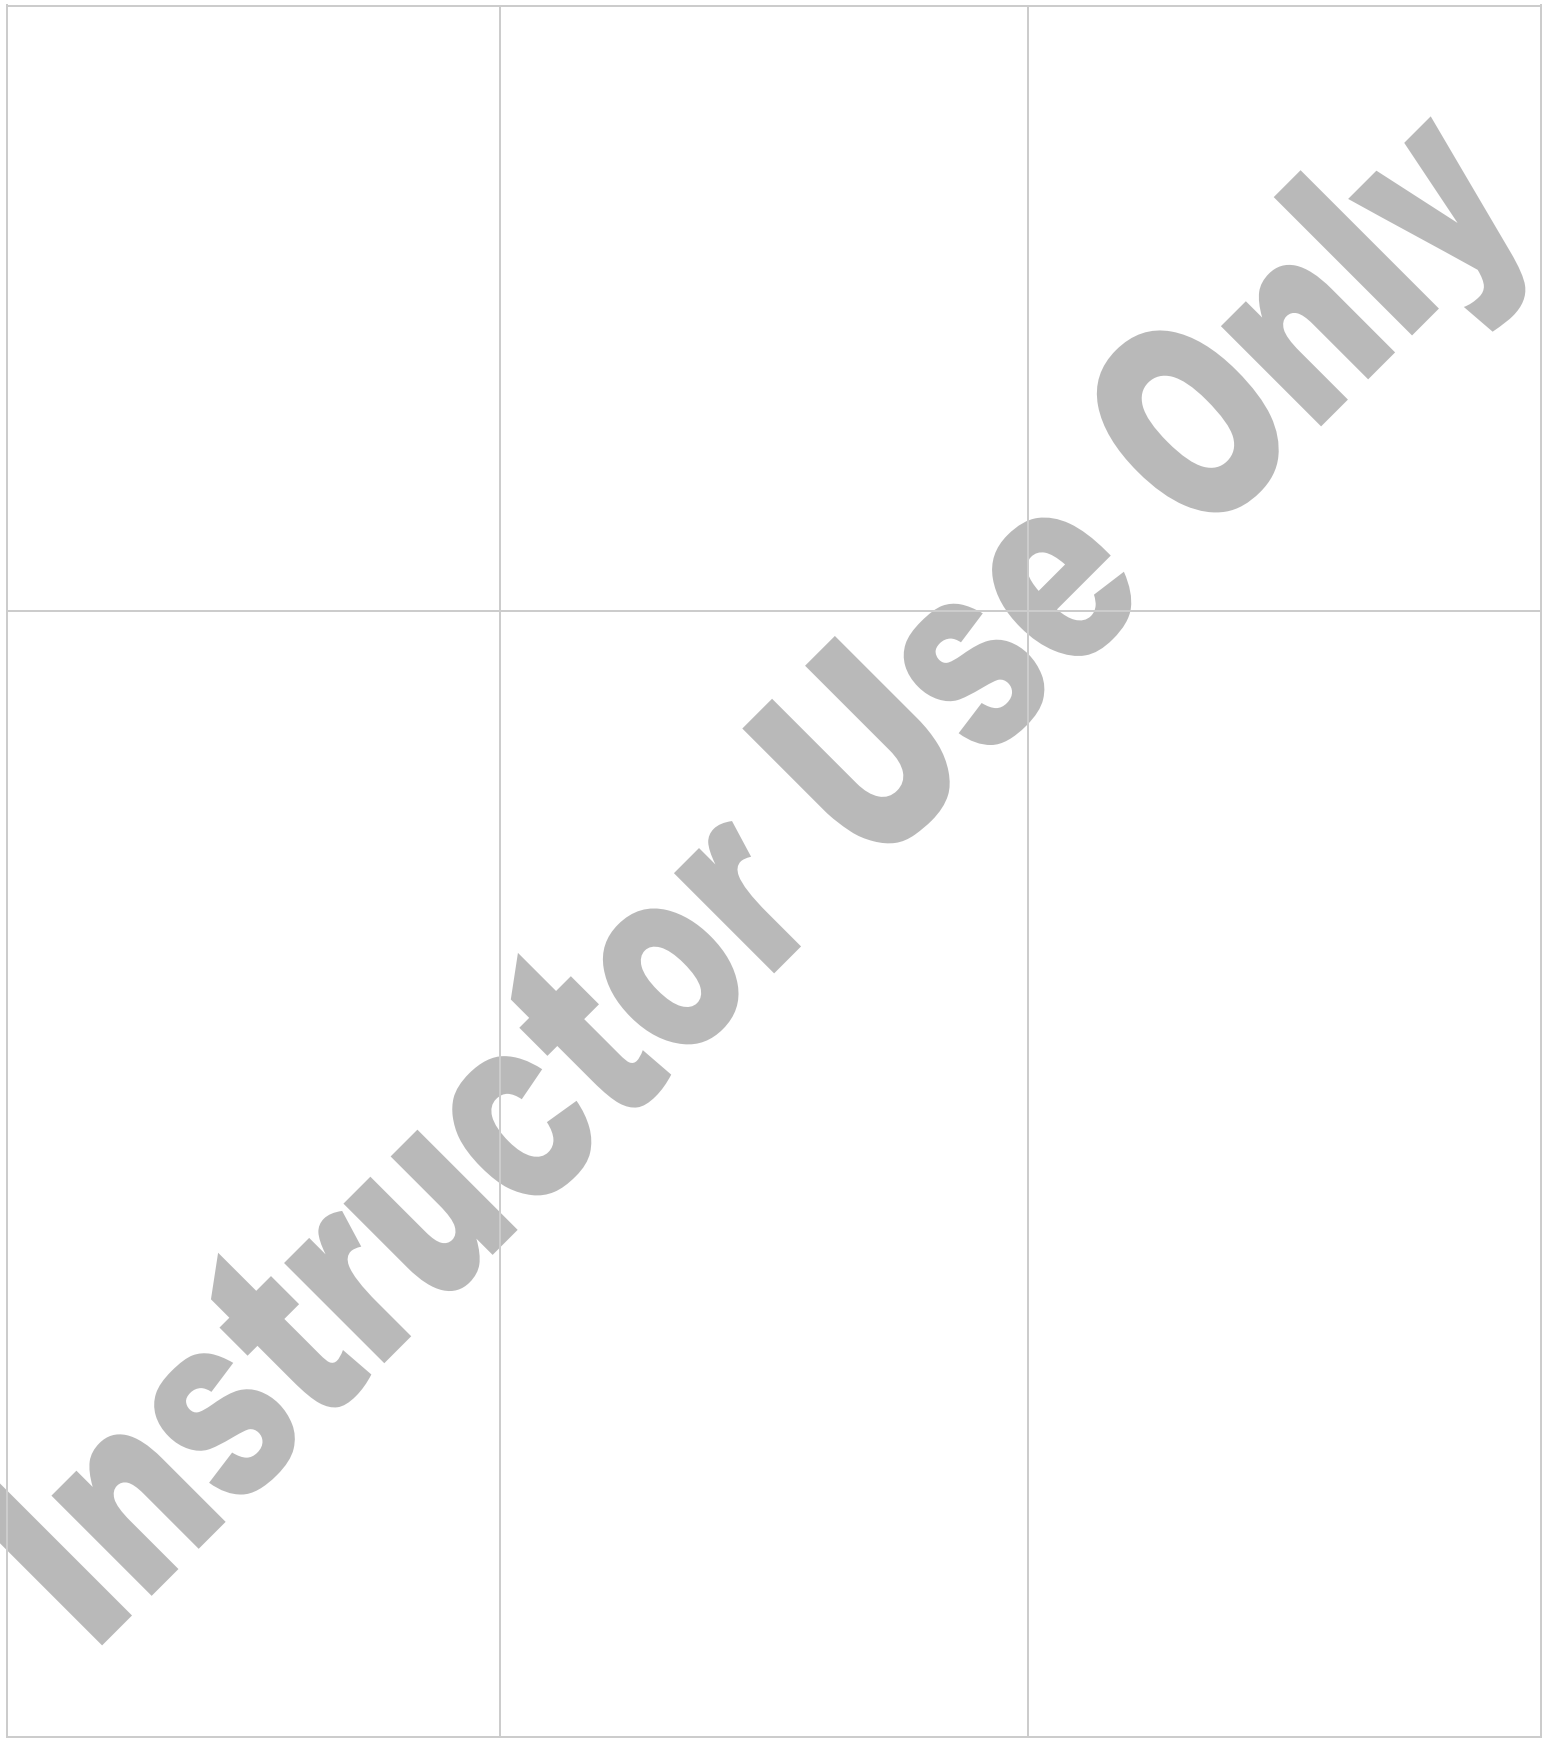
- 3.1.3 Configure NTFS permissions
- 4.2 Implement Encryption Techn

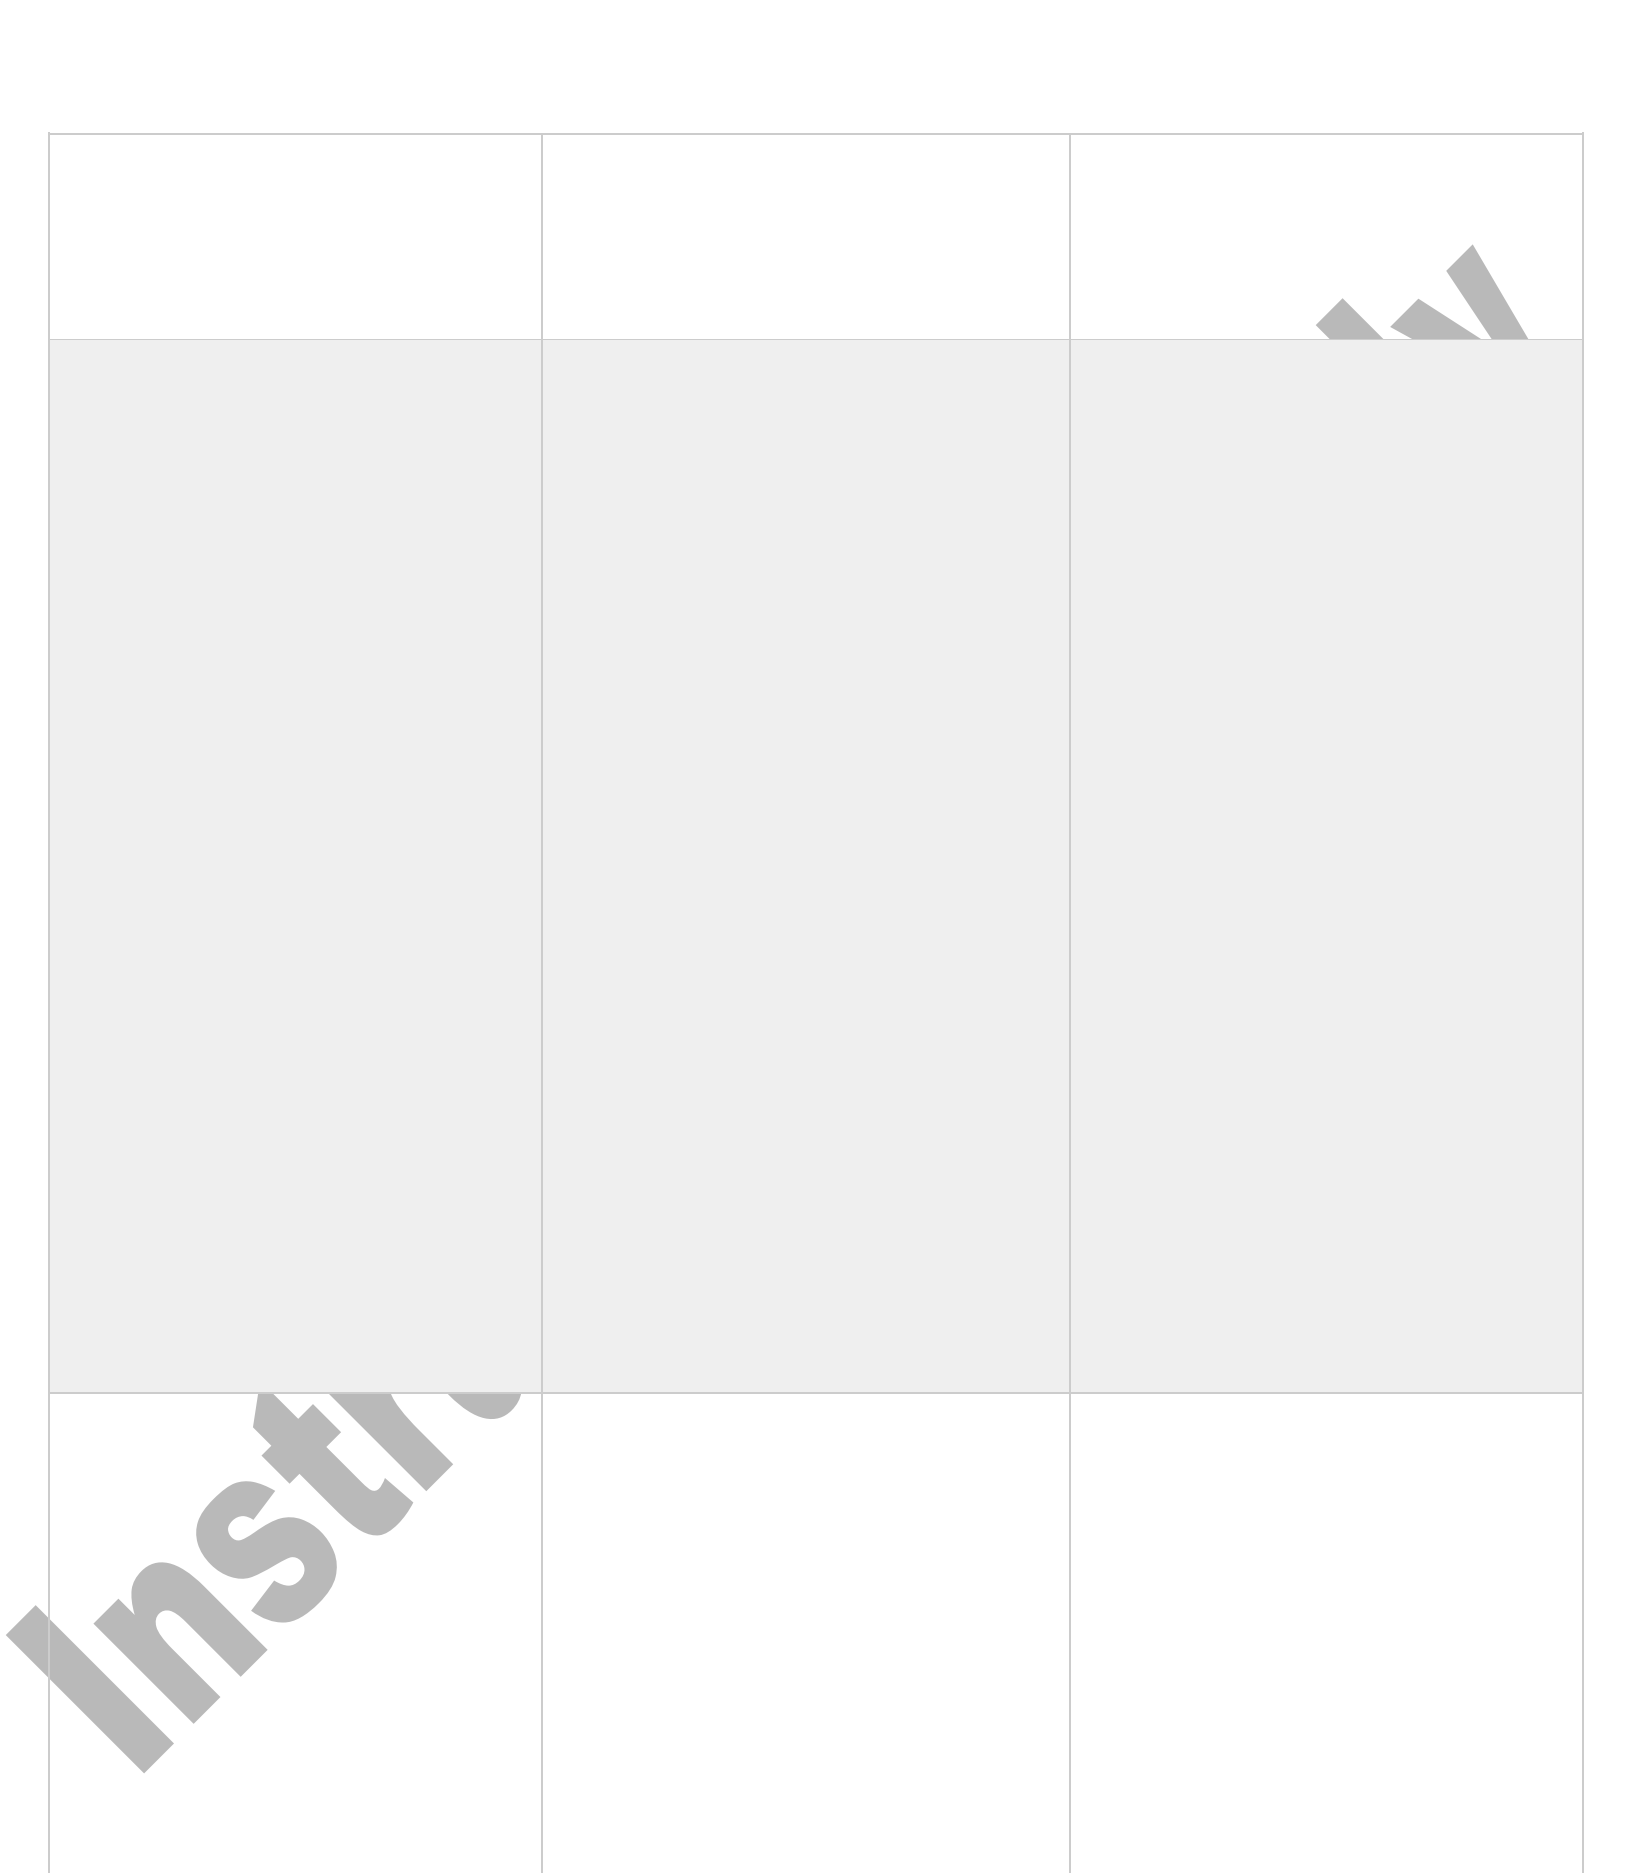
		• 4.2.2 Encrypt files ologies
8 3	Linux Host Security	2.1 Harden physical access

	Wireless Controller	









B.1.3 How to take the Pro Exam

To take the TestOut Security Pro Certification exam, you must first schedule the exam with an instructor or an administrator.

You are encouraged to budget your time and to keep moving through the exam so you can complete it within the time limit. Begin an exam at the scheduled exam time. Follow these steps to start the exam:

- Log in to LabSim.
- Select the **Certifications** tab from the top navigation menu.
- Navigate to the certification.
- Select **Start Exam** and read the instructions.
- Select **Start Exam** when you are ready to begin the exam.

Exam Notes

- When you purchase a TestOut course, the Pro Certification exam is included with the course. The course license must be active for you to take the exam.
- Unlike the practice exams, the TestOut Pro certification exams are assessment exams that do not allow students to check their answers or get instant feedback.
- The exam may be attempted only once per exam voucher.
- If you do not pass the exam, you may purchase a retake exam voucher online.
- Do not click **Start Exam** until you are ready to complete the certification exam. Starting the exam and exiting will use the exam voucher.

B.1.4 Pro Exam FAQs

TestOut Pro Certification Frequently Asked Questions (FAQs)

For the most up-to-date TestOut Pro Certification FAQs, visit TestOut Pro Certification at https://w3.testout.com/certification/pro-exams/resources/pro-exam-faqs .

B.2 TestOut Security Pro Domain Review

This section is a practice review that contains all the questions related to the TestOut Security Pro exam. Use these questions to prepare for the TestOut Security Pro exam.

The questions in this section are not randomly generated. You will receive the same set of questions each time you open a new practice session.

This practice review has:

- 84 lab simulations
- No time limit
- No pass/fail score
- A percentage score at the end of the session

The student's score should not be used as part of the student's grade. This section is meant to be used as a practice review only. If you need to include a score in the student's grade, use the TestOut Security Pro Certification Practice Exam score.

After you finish the practice review, you can print the score report to use for further review.

B.2.1 Pro Domain 1: Identity Management and Authentication (Section Quiz)

B.2.2 Pro Domain 2: Physical and Network Security (Section Quiz)

B.2.3 Pro Domain 3: Host and Application Defense (Section Quiz)

B.2.4 Pro Domain 4: Data Security (Section Quiz)

B.2.5 Pro Domain 5: Audit and Security Assessment (Section Quiz)

B.3 TestOut Security Pro Certification Practice Exam (Section Quiz)
